Dr. Clarke's account of the iron mines he visited at Persberg, which is of a very interesting character, will be read with interest by the English metallurgist. The author's visit to these mines was made after he had personally inspected many of the principal works of the same nature in other countries, and especially in his own. For the last ten years of his life he had been much in the habit of seeing similar works: it is not therefore owing to any surprise at the novelty of the scene before him, that he has now to mention the astonishment he felt when he arrived at the mouth of one of the great Persberg mines; but he is fully prepared to say of it, and with truth, there is nothing like it in all that he has beheld elsewhere. 'For grandeur of effect, filling the mind of the spectator with a degree of wonder which amounts to awe, there is no place where human labor is exhibited under circumstances more tremendously striking. As we drew near to the wide and open abyss, a vast and sudden prospect of yawning caverns and of prodigious machinery prepared us for the descent. We approached the edge of the dreadful gulph whence the ore is raised, and ventured to look down; standing upon the verge of a sort of platform, constructed over it in such a manner as to command a view into the great opening, as far as the eye could penetrate amidst its gloomy depths: for, to the sight, it is bottomless. Immense buckets suspended by rattling chains were passing, and we could perceive ladders scaling all the inward precipices upon which the work-people, reduced by their distance to pigmies in size, were ascending and descending. Far below the utmost of these figures, a deep and gaping gulf, the mouth of the lowermost pits, was, by its darkness, rendered impervious to the view. From the spot where we stood down to the place where the buckets are filled the distance might be about seventy-five fathoms; and as soon as any of these buckets emerged from the gloomy cavity we have mentioned, or until they entered into it in their descent, they were visible; but below this point they were hid in darkness. The clanking of the chains, the groaning of the pumps, the hallooing of the miners, the creaking of the blocks and wheels, the trampling of horses, the beating of the hammers, and the loud and frequent subterraneous thunder from the blasting of the rocks by gunpowder, in the midst of all this scene of excavation and uproar, produced an effect which no stranger can behold unmoved. We descended with two of the miners and our interpreter into this abyss. The ladders, instead of being placed like those in our Cornish mines, upon a series of platforms as so many landing-places, are lashed together in one unbroken line, extending many fathoms; and, being warped to suit the inclination or curvature of the sides of the precipices, they are not always perpendicular, but hang over in such a manner that even if a person held fast by his hands, and if his feet should happen to slip, they would fly off from the rock, and leave him suspended over the gulf. Yet such ladders are the only means of access

to the works below; and, as the laborers are not accustomed to receive strangers, they neither use the precautions, nor offer the assistance, usually afforded in more frequented mines. In the principal tin-mines of Cornwall the staves of the ladders are alternate bars of wood and iron; here they were of wood only, and in some parts rotten and broken, making us often wish, during our descent, that we had never undertaken an exploit so hazardous. In addition to the danger to be apprehended from the damaged state of the ladders, the staves were covered with ice or mud, and thus rendered so cold and slippery that we could have no dependence upon our benumbed fingers, if our feet failed us. Then to complete our apprehensions, as we mentioned this to the miners, they said, 'Have a care! It was just so, talking about the staves, that one of our women fell, about four years ago as she was descending to her work.' 'Fell,' said our Swedish interpreter, rather simply. 'and pray what became of her?' 'Became of her,' continued the foremost of our guides, disengaging one of his hands from the ladder, and slapping it forcibly against his thigh, as if to illustrate the manner of the catastrophe, 'she became (pankaka) a pancake.'

'As we descended farther from the surface, large masses of ice appeared, covering the sides of the precipices. Ice is raised in the buckets with the ore and rubble of the mine: it has also accumulated in such quantity in some of the lower chambers, that there are places where it is fifteen fathoms thick, and no change of temperature above prevents its increase. This seems to militate against a notion, now becoming prevalent, that the temperature of the air in mines increases directly as the depth from the surface, owing to the increasing temperature of the earth under the same circumstances; and in the same ratio; but it is explained by the width of this aperture at the mouth of the mine, which admits a free passage of atmospheric air. In our Cornish mines ice would not be preserved in a solid state at any considerable depth from the surface.

'After much fatigue, and no small share of apprehension, we at length reached the bottom of the mine. Here we had no sooner arrived, than our conductors, taking each of us by an arm, hurried us along through regions of thick-ribbed ice and darkness, into a vaulted level, through which we were to pass into the principal chamber of the mine. The noise of countless hammers, all in vehement action, increased as we kept along this level; until at length subduing every other sound we could no longer hear each other speak, notwithstanding our utmost efforts. At this moment we were ushered into a prodigious cavern, whence the sounds proceeded; and here, amidst falling waters, tumbling rocks, steam, ice, and gunpowder, about fifty miners were in the very height of their employment. The magnitude of the cavern, over all parts of which their labors were going on, was alone sufficient to prove that the iron ore is not deposited in veins, but beds. Above, below, on every side, and in every nook of this fearful dungeon, glimmering tapers disclosed the grim and anxious countenances of the miners. They were now driving bolts of iron into the rocks, to oore cavities for the gunpowder for blasting. Scarcely had we recovered from the stupefaction occasioned by our first introduction into this Pandæmonium, when we beheld, close to us, hags more horrible than perhaps it is possible for any other female figures to exhibit, holding their dim quivering tapers to our faces, and bellowing in our ears. One of the same sisterhood, snatching a lighted splinter of deal, darted to the spot where we stood, with eyes inflamed and distilling rheum, her hair clotted with mud, dugs naked and pendulous; and such a face, and such hideous yells, as it is impossible to describe:—

Black it stood, as Night—fierce as ten Furies—
Terrible as hell.

If we could have heard what she said, we should not have comprehended a syllable; but as several other Parcæ, equally Gorgonian in their aspect, passed swiftly by us, hastening tumultuously towards the entrance, we began to perceive, that, if we remained longer in our present situation, Atropos might indeed cut short the threads of our existence; for the noise of the hammers had now ceased, and a tremendous blast was near the point of its explosion. We had scarcely retraced with all speed our steps along the level, and were beginning to ascend the ladders, when the full volume of the thunder reached us, as if roaring with greater vehemence because pent among the crashing rocks, whence, being reverberated over all the mine, it seemed to shake the earth itself with its terrible vibrations.'

The following is an improved process for *hardening* steel. Articles manufactured of steel for the purpose of cutting are, almost without an exception, hardened from the anvil; in other words, they are taken from the forger to the hardener without undergoing any intermediate process; and such is the accustomed routine, that the mischief arising has escaped observation. The act of forging produces a strong scale or coating, which is spread over the whole of the blade; and, to make the evil still more formidable, this scale or coating is unequal in substance varying in proportion to the degree of heat communicated to the steel in forging; it is, partially, almost impenetrable to the action of water when immersed for the purpose of hardening. Hence it is that different degrees of hardness prevail in nearly every razor manufactured: this is evidently a positive defect; and, so long as it continues to exist, great difference of temperature must exist likewise. Razor-blades not unfrequently exhibit the fact here stated in a very striking manner: what are termed clouds, or parts of unequal polish, derive their origin from this cause, and clearly and distinctly, or rather distinctly though not clearly, show how far this partial coating has extended, and where the action of the water has been yielded to, and where resisted. It certainly cannot be matter of astonishment, that so few improvements have been made in the hardening of steel, when the evil here complained of so universally obtains as almost to warrant the supposition that no attempt has ever been made to remove it. The remedy, however, is easy and simple in the ex-

treme, and so evidently efficient in its application, that it cannot but excite surprise, that, in the present highly improved state of our manufactures, such a communication should be made as a discovery entirely new.

Instead, therefore, of the customary mode of hardening the blade from the anvil, let it be passed immediately from the hands of the forger to the grinders; a slight application of the stone will remove the whole of the scale or coating, and the razor will then be properly prepared to undergo the operation of hardening with advantage. It will be easily ascertained, that steel in this state heats in the fire with greater regularity, and that when immersed, the obstacles being removed to the immediate action of the water on the body of the steel, the latter becomes equally hard from one extremity to the other. To this may be added that, as the lowest possible heat at which steel becomes hard is indubitably the best, the mode here recommended will be found the only one by which the process of hardening can be effected with a less portion of fire than is, or can be, required in any other way.

We will now direct our reader's attention to a very important, though simple process connected with the hardening and preservation of steel, for which the scientific world is mainly indebted to Mr. Pepys of the Poultry. In his manufactory the tempering, or reduction of the hardening, is not governed by the color only, but by a more accurate method; the exact variations of temperature are given in a fluid, into which a Fahrenheit's thermometer graduated to the boiling point of mercury is immersed, and the delicacy of this operation may be sufficiently understood from the various colors produced on the steel at the various temperatures shown by the thermometer. The change or scale takes place at 430°, and finishes at nearly 600°. Nine changes of colors are observable at about 20° distance of each other.

430° Slight color inclining to yellow.
450 Straw color, pale.
470 Yellow.
490 Brown.
510 Brown with purple spots.
530 Purple
550 Bright blue.
560 Blue.
600 Blackish blue inclined to scale or oxyd.

From 430 to 470 is chiefly employed for razors and some of the finer edged surgical instruments, 470 and 490 for penknives, and some pointed instruments. From 510 to 550 includes pocket-knives, table-knives, carvers, scissors, &c., &c.

The experience of the workman is much required, and also a knowledge for what purpose the edge is to be employed, during these three ranges of temperature.

Of amalgamation.—The process of amalgamation in procuring the precious metals, to which we have already briefly adverted, is but little practised in this country, and yet its value has been generally admitted by the leading chemists both in South America and Europe. The treatise on this subject published by Baron Born in Germany is very rare, and but little known in this country, and we have been favored by a perusal of those parts that have been since translated by Mr. Raspe, which now makes the whole process both plain and intelligible. Amalgamation is the solution of metals in quicksilver. It depends on their elective affinities. Its object and use is either the purification of gold, silver, and other metals, or other mechanical purposes, of which there is no occasion to speak in this place.

The affinity of quicksilver with gold and silver was well known in the remotest antiquity. Vitruvius tells us how gold may be recovered by it from embroidery and old clothes. On this affinity also depends the gilding of metals and brass, which Pliny mentions. All our gold and silver smiths, and many other trades, are acquainted with it. From time immemorial quicksilver has been used in the streaming for gold, in order to purify, and collect into one body the gold dust, which is dispersed in the sands. To obtain these ends, the auriferous sand, brought into a smaller compass by washing, is mixed and triturated with quicksilver; and the amalgam, or solution of the gold, is pressed through a piece of leather, which separates the abundant quicksilver. The Gipsies on the banks of the Arannyos in Transylvania, the Russians on the banks of the Okka, the Americans in their stream works in Chili, and the Germans on the banks of the Rhine, use it in the same manner. The miner applied it for the same purposes, fetching auriferous stones from under ground, and pounding them to sand, which he afterwards triturated with quicksilver in particular mills. Of these quick mills, Agricola has left us an accurate account. Metallurgy being much improved in Germany since the days of Agricola, it was found that only part of the gold was extracted in these mills; that, to obtain the whole, the leavings must go to the fire; and that the gold taken up by the quicksilver must be parted from the silver. All this took away much of the credit of these quick mills; they began soon to be looked upon as superfluous. The gold was separated by washing, only from the first and richer stuff of the stamps; the poorer sorts went to the fire, and the gold was parted from silver by quartation. However, in some mines in the Zillerthal in Tirol, at Gasteris in Salzburgh, in some gold works in Savoy and Chili, which produce native gold, these quick mills are still in use for the purposes of dry or wet amalgamation. By Schlutter's account, the native silver of Kongsberg in Norway was also extracted in quick mills, till they fell into disrepute on account of the large quantities of silver they left in the residuum.

Burning and calcination of the ores promote amalgamation, in so far as it promotes their pulverisation, and assists the quicksilver, chiefly in the treatment of gray silver and copper ores. The best symptom of sufficient calcination is their change of color and loss of brightness. All bright ores must be calcined, but with great care that no vitriol may be disengaged, for that prevents the amalgamation, or, by the subsequent saline additions, produces a salt, which dissolves the metals, and makes them unfit to unite with the quicksilver. These and other circumstances

make fusion and treatment in furnaces frequently preferable to amalgamation, chiefly where there is plenty of wood and firing. Circumstances must determine whether it be better to grind and pulverise them before or after calcination. Their value and contents are better found by the calcination of the pulverised stuff. During the calcining fire it must be constantly stirred and turned about. From time to time some powder is taken from the furnace, and tried with quicksilver and salt, which presently shows the nature of the ore. The inspissation of the quicksilver, or the grain of the stuff, informs the artist whether or what addition it may require, and whether the calcination is perfected or not. The calcination of ores in lumps does not act equally upon all their parts; nor can the fire penetrate them every where. But it is attended with a smaller loss of dust, and saves much trouble and expense in the stamps and mills.

The irony ores, which resist the fire longer, are calcined with an addition of sulphur, or of sulphureous and antimonial stuff, proportioned to the iron they contain. Sulphureous and antimonial ores require calcination with iron scoria. The arsenical ores, or those which are mixed with orpiment and sandarac, are calcined with lead glance; and those which are infected with light or black bitumen must be exposed to the calcining fire with iron scoria or pounded limestone.

To determine the impurities of ores, and their proper additions, pound them coarsely, and throw them upon a heated iron plate. If the smoke be white or black, it is a symptom of white or black bitumen; if yellow, it argues orpiment; if red, sandarac; if yellow and greenish, it implies sulphur. The ores or halvan stuff must never be calcined with salt, for it would calcine the silver. The duration of the calcining fire cannot be determined but by the apparent loss of brightness and change of colors which the ores undergo, and by the test of quicksilver; if, when triturated with some of the calcined stuff, it remains white and pure, and takes a silver color, the calcination is completed. Besides this general rule, there are some other symptoms. If antimonial and sulphureous ores do no longer send forth a suffocating or disagreeable smoke, if the thick black smoke of bituminous ores turns white, and if the silver in the stuff appears in white glittering sparks, in all these cases the calcination is perfected. Able masters will obtain the same and even in the calcination of paco's, negrillo's, and other vitriolic ores, though they require a longer calcining heat and various additions of alum and salt; but then they require no further addition in the subsequent operations, and the quicksilver will take up all their silver in the course of four days. Also less quicksilver will be lost; for, as there is no occasion for the frequent turning and working of the heap, it cannot be worked into impalpable and irrecoverable dust.

One circumstance cannot be too strongly recommended; it is, that vitriolic ores must always be lixiviated before they go to the calcining fire. If the calcined stuff be suspected of being vitriolic, it must be tried by quicksilver; if it takes a lead color, the stuff must be washed till iron put into it does no longer take a copper color. The lixivium of the vitriolic stuff, or ore, is preserved as a useful addition to some ores.

Before the master dresses his heap, he mixes the fine and sifted powder, and takes a sample of three or four pounds for the assay by fire. According to the produce he calculates the contents of the whole for his government. Moreover, he tries the same with quicksilver, to come at the method how the whole is to be treated, and to learn what additions will be required. First he lixiviates the stuff, to extract the sulphate of copper. Then he takes one pound of the lixiviated stuff and tries it by trituration with salt and quicksilver, carefully observing its color and change. If the quicksilver takes the color and form of silver filings, and these quicksilver flakes turn thinner and thinner, it is proof that the amalgamation goes on successfully, and that there is no occasion for any addition. The whole is stirred from time to time, till the quicksilver seems to diminish, and to recover its natural globular form without dividing into small globules. Then the stuff is washed, all the silver being then completely taken up. Formerly the complete extraction of silver by amalgamation, without other additions, was looked upon as impossible; but the ores of Verenguela de Pacagés are actually treated only with quicksilver and salt, and yet they yield their full produce. If the quicksilver takes a lead color, which the Spanish miners call plomo, then the heap requires additions of iron, lead, tin, quicklime, and ashes; for, with them, any silver or ore may be amalgamated. If it turns black, iron is added; if a light lead color tin,; if a dark lead color, lead; if it takes a yellowish or gold color, which implies copper, it requires an addition of lime.

It often divides into small white powdery globules, in consequence of the gravity or hardness of the mineral. This chiefly happens in the amalgamation of lead glance, marcasite, and other bright minerals; or in that of uncalcined hard matrices or loadstones. It likewise arises from too much stirring; and may be obviated by previous calcination of the stuff, or by less stirring. Yet this quicksilver dust is hardly to be avoided in great operations. It serves the workmen for a measure of their progress, nay even for a direction how to operate. This dust is called by different names. The whitish dust, which arises simply from too great division, is called quicksilver dust. What arises from the amalgama of lead and tin is called dust of addition; and what comes from the silver amalgama, silver dust. They are easily distinguished. Quicksilver dust is white, without any quickness, hardly moving when the stuff is stirred with water; it rather sticks to the bottom, and on rubbing it between the fingers it clots into globules. The silver dust sinks towards the coarser stuff on the bottom, and floats about in larger or smaller flakes; rubbed and pressed between the fingers it turns into an amalgama. The dust of addition is, as it were, intermediate between the two. Pressed between the fingers or rubbed, it unites with the quicksilver, which

had begun to combine with silver. These different powders are produced during the amalgamation and washing, by too frequent stirring and turning, chiefly when lead, marcasite, and irony ores are in the mixture; also by sulphate of copper, which in particular brings on this too minute division of the quicksilver; and likewise by too abundant addition of salt, which inspissates the water, and prevents the quicksilver particles from falling to the bottom. They are commonly of the color of quicksilver, and of a white, black, and lead color; like the color of the quicksilver they indicate the various imperfections of the heap in hand, and their respective remedies.

When the master is fully informed, by smaller assays, of the quality and produce of his stuff, of the additions it requires, and of the circumstances which may attend his operations, he accordingly regulates his heap and his proceedings. The heap is wetted with water and mixed with the proper quantity of salt. In the beginning, but one-third of the quicksilver and one-half of the tin and lead are added. During the first two days, it is but once turned over every day, because the quicksilver then uncombined with silver would be apt to fly into very minute globules, and consequently bring on great loss of quicksilver dust. Moreover, too much quicksilver chills the heap, and its amalgamation should rather be assisted by heat. For these reasons it is but gradually added; and though, for want of quicksilver, the work should but slowly proceed in the beginning, yet this may easily be remedied afterwards.

The additions of tin and lead are always thrown into the heap together with the quicksilver. Too much of either hurts the process, for they deaden the quicksilver, and make it unfit for taking up the silver.

Both quicksilver and other additions must be proportioned according to circumstances; observing that the quantities added at a time must be less and less, the more the amalgamation approaches perfection: otherwise the whole would be overloaded with, and swim in quicksilver, whereas it should be kept rather dry, and two parts of amalgama to be in the heap to one of quicksilver. Some masters are of opinion, that abundance and superfluity of quicksilver cannot be hurtful, provided there be a sufficient quantity or proportion of additional ingredients. But this very abundance is exceedingly hurtful, by the great quantity of quicksilver dust which must arise from the turning of the stuff; moreover, if by some accident the additional ingredients should be wasted or destroyed, the dust of addition will change into quicksilver dust, which, having hardly any weight, will not fall to the bottom, but swim on the surface, and run off with the water. If the addition is lime, the whole must be added at once, and the heap be turned over for two or three days, till the quicksilver is added. Too much prevents the combination of the two metals, and any inconveniency may be remedied but this.

The heaps are frequently turned and worked over, that the quicksilver may be thoroughly mixed with the stuff, and take up the silver contained in it. The turning heats the quicksilver and so far assists its attraction. The frequent rubbing purifies the silver. From the difference of their constituent parts, the heaps and the difference of ores are subject to different accidents. The respective progress and obstacles of the amalgamation best appear by fine pulverisation of the stuff; and the quicksilver is the mirror in which all that appears clearly.

The quicksilver deadened by too abundant addition of lead, tin, iron, and lime, loses its oval and affects a vermicular form. Shaken in a glass or other vessel by itself, without any water, it adheres to the sides as it were in strings like thread. Thus circumstanced it is unfit for taking up silver. Its best remedy is sulphate of copper, or the lixivium of vitriolic ores, which was spoken of before. The other base metals, which by their cold nature had deadened the quicksilver, are changed by this sulphate of copper into an oxide, the quicksilver is thereby warmed and restored to life and activity. For the same purpose copper powder is thrown into the heap, and vitriol is the chief ingredient of all the additions which are intended to warm the quicksilver. Thus copper ore is calcined, and when ground fine two parts of it are mixed with one part of salt. Then it is calcined once more, adding half a pound of brass filings to 1 cwt.; or equal parts of fine and coarse stuff and salt are calcined together; or equal parts of copper ore, coarse stuff, and salt; or equal parts of copper ore, coarse stuff, iron scoria, and of the fine silver stuff. They are formed into a paste and cakes which are calcined. These solvents must be thrown into the heap very cautiously, and in consequence and by the direction of smaller assays, which determine what quantity of vitriol will do it good, or disagree with it. The heaps which have too much vitriol, and no additional remedies, give a lead color to the quicksilver. Its quickness is not affected, any more than that its smaller particles appear not in a convex but spherical form.

To obviate this evil, and to protect the quicksilver against the corrosion and action of the vitriol, iron is added, as having a particular power to recal it to life, and to bring it again into one body. But, as there is no certain rule for its proportion, small samples of the heap should be submitted to experiment, nor the heap be turned over till that proportion be fully determined. Sometimes, on examining the heap whilst it is turning, the quicksilver appears in small globules connected as a bunch of grapes. This implies salt, which covers the quicksilver and prevents its combination. It is remedied by the addition of some coarse stuff, which, on being turned with the heap, cleanses the quicksilver. Some add ashes; but the best and most natural remedy is alum, which abounds at Potosi, and whitens the silver. If the heap be not turned equally, and the quicksilver be not added at the proper time, or the silver does not unite with it, dry silver will arise, and lie on the coarser stuff like cobweb, which, if not skimmed off in time, is carried off by the washing water. To collect this dry silver, and the finest quicksilver dust, some silver amalgama is pressed upon

it through a chamois skin, and the whole is once more turned and worked over. The frequent turning, the heat of climate and season, the fermentation produced in the heap by the vitriol, and other additions, all co-operate in the amalgamation, and promote its success; whereas cold weather, neglect of stirring, and the lead color of the quicksilver prevent it.

It is very difficult to determine upon the maturity of the heap, when all the silver is taken up, and when it may go to the washing. And yet much depends upon it. If washed too soon, silver is lost in the leavings; if worked too long there is loss of quicksilver, time, and labor. The symptoms of maturity hitherto mentioned are all of them exceedingly uncertain and fallacious. The heap may appear not to require any additional quicksilver; the silver dust may appear to be completely collected; that of quicksilver may begin to make its appearance; the amalgama may begin to appear pure, and to show a gold color; and yet silver may remain in the leavings. The most infallible test of the maturity of the heap is the assay of the triturated stuff by fire. If no silver is produced thereby, then so much quicksilver is thrown into the heap, that it may contain three parts amalgama to two of silver, or at least one part quicksilver to two of amalgama. By this additional fresh quicksilver, all the dust of quicksilver, and the dry and uncombined silver, are perfectly collected; the amalgama is the heavier for it, and sinks the more readily to the bottom, when brought to the washing-tub. Some clean quicksilver is also put into the bottom of this tub; the inside of which must be lined with iron plate, well cleaned, and rubbed with quicksilver. The stuff brought into the tub must be diluted with a great quantity of water, and be stirred round with a pestle, lined with iron plate in such a manner that it may turn round six times one side, and six times the other, always touching the bottom; the unconnected bodies of quicksilver and amalgama are thereby to meet, to combine, and to fall to the bottom. To recover the salt, which had been mixed with the heap, the water, which is first thrown upon the stuff in the washing-tub, is collected, and by evaporation the salt falls to the bottom. The whole having thus been washed over, and the quicksilver being collected into one body, nothing remains in the tub but some fine quicksilver dust, which ought to be collected by a piece of leather or cloth. Then the whole is pressed through a piece of leather or wet cloth. The amalgama thereby obtained is beaten into a pyramidal or conical mould, and called pinna. 100 lbs. of amalgama commonly produce a pinna of silver of forty marcs. The finest particles of silver pass with the quicksilver through the pressing bag; and in the boxes, in which it is preserved for further use, crusts of silver amalgama collect at the bottom. More silver runs off with warmed quicksilver. The amalgama formed into conical pinnas is commonly distilled from earthen retorts into similar receivers, in order to free it from its quicksilver; or the same distillation is performed in iron vessels, by which nothing is lost of the quicksilver fumes.

P. Joseph Acosta gives the following account of the amalgamation of gold and silver ores:—'Commonly 6000 or 7000 cwt. of quicksilver are consumed at Potosi in the dressing of the ore, not to mention what is recovered from the leavings of the first washing. These leavings, called lamas, are burnt in particular furnaces in order to extract the remaining quicksilver. There are upwards of fifty such furnaces near Potosi and Tarapaja. The ore annually refined amounts to about 300,000 cwt. from the leavings of which nearly 2000 cwt. of quicksilver are recovered. Let us observe that the ores are of a different nature. Some are rich, and require but little quicksilver; others produce little and consume a great quantity; others again produce and destroy much of it. Commonly the richest requires most, and vice versâ; and profit and loss in mining depend on the quality of the ore. The ore is first pulverised in mills, and then passed through iron or brass sieves. Properly built and regulated, these mills will grind 30 cwt. in the space of twenty-four hours. The pulverised stuff is put into heaps in the open air, and salt is mixed with it in the proportion of 5 cwt. to 50 cwt. in order to macerate and cleanse it of its impurities, that it may be the better acted upon by the quicksilver. Upon these heaps, and whilst they are stirring, the quicksilver is pressed through a coarse cloth, through which it comes as a drizzling rain in small globules. Before the fire-places were invented, the ore was repeatedly kneaded with quicksilver in wooden troughs, and formed into large round masses, which were left in that form for a couple of days. Then they were worked again till the quicksilver appeared embodied with the silver, which sometimes would take twenty and more, but at least nine days. When it was found that fire assists this incorporation of the silver, ovens were built, in which the mixture of salt, quicksilver, and ores, is generally heated, and the quicksilver appears to be incorporated in the course of five or six days. When the quicksilver has taken up the silver, and wholly separated it from its matrix, the lead and the copper, the ovens are opened, the stuff is taken out, and the quicksilver is expelled and recovered in the following manner:—

'The mixture is put into water-troughs, and stirred therein by means of mills and water wheels, whereby the earthy and extraneous particles are washed away, and the quicksilver with the silver settles at the bottom. The sediment looks like sand. It is further washed over in flat plates, and perfectly cleansed; what goes off with the water is collected, and further made use of under the name of relaves.

'When in this manner the amalgama is cleansed and bright, it is put into a cloth and squeezed out. The uncombined quicksilver runs off, and the remaining body of amalgama contains five parts of quicksilver, and one of silver. This amalgama is made into silver masses, called pinnas, which have the form of a sugar loaf, are hollow within, and commonly weigh 100 lbs. To expel the quicksilver, they are exposed to a strong fire, and covered with an earthen cap or helmet, of the form of a sugar loaf, which is externally surrounded with coal. The heat evaporates the quicksilver in the form of steam,

which coming in contact with the earthen cover is condensed, and runs off by a pipe into a vessel filled with water, so that the quicksilver is recovered, and the silver purified. Though the silver still appears in the form of amalgama, yet it loses five parts of its weight, and looks spongy. The silver, thus collected and purified, is so fine that silversmiths cannot work it without alloy, and even in the mint some alloy must be added.'

Another writer on this subject says, 'The ores must be calcined in furnaces like lime-kilns, and the calcining fire must be kept up according to the nature of the ores; afterwards they may be pulverised in hand, horse, or water-mills, or in stamps. The pulverised stuff is passed through fine iron sieves, and then put into earthen or copper vessels by 20 or 10 cwts. More or less salt is mixed with it, according to circumstances. The light-colored stuff requires 50 lbs. per 1000, the darker somewhat more. To this is to be added 5 lbs. dry tartarus, 2 lbs. pulverised horn, and 3 lbs. brick-dust. More or less of these additions is required; but that depends so much on the nature of the ores, that some of them require but a small part of these additions. After this mixture has been put into the boiler, a sufficient quantity of water must be added, that the whole may be pounded into a kind of paste, neither too thick nor too thin; and the vessels must be exposed to the sunshine, for the operation succeeds better in summer than winter, when it is performed in warm rooms. When the paste begins to dry, some water must be added, and it must be worked over by pounding three or four times a day. At the expiration of three or four days, various colors appear on the surface. Then 15 lbs. of sulphur per 1000 must be added, and the whole must be worked over again. At last 100 lbs., or, if the ores are of a mild nature, a less quantity of quicksilver is added; the whole mass is carefully worked over, and left at rest to settle for about ten hours. Then fire is kindled under the boiler, and the stuff contained in it must be stirred or triturated for two days together, observing that a proportionate quantity of water may always keep it sufficiently liquid and diluted. At last, let it repose for twelve hours; let it dry, and take it out. If the ores were rich and well worked, particles and globules of quicksilver amalgama appear in it, which are collected, washed out, and kept for further use. The leavings are carried to a place fit for washing them over. This place must be on the slope of a hill, where a kind of pit is dug out and lined with brick and mortar. It must hold about 25 cwt. of the triturated stuff. Running water is led upon it, and it must be stirred without interruption. The superflous water runs off over the rim of the pit, and carries off the lighter particles gradually. When all the earthy and stony particles are thus washed off, the silver amalgama at the bottom is taken out, and, together with the before said grains or clots of amalgama, it is pressed through a hempen or coarse linen cloth, which may be done by hand, or other mechanical contrivances. The quicksilver, which comes through clean, is kept for future use, the amalgama is evaporated in particular furnaces, and the remaining silver is run into ingots. In this manner all the silver is extracted from every kind of ore in a very short time; and, on account of its inconsiderable expense, even poor ores and poor mines can be worked to advantage.

'In order to extract the gold from its ores, the following practice is put in process:—The auriferous sand, which contains gold-grains and gold-dust, is concentrated by washing, and without any calcination it goes to the just mentioned washing-pit, which for this purpose need not be spacious. On its upper part is fixed a square launder, about twelve feet long, which on its bottom is covered with a woollen cloth, for the purpose of keeping the gold-dust, which may be carried off with the water and stuff gently stirred in the pit. When the water carries off no more mud, but runs off clear, the farther supply is stopped, the water in the pit is pumped or taken out in buckets; the coarser sand in the bottom is separated or scraped off by the hands, and the finer heaviest sand at the bottom is mixed with quicksilver. Then it is squeezed through a piece of cloth; the quicksilver comes off without any gold, which, separated from the sand, remains as an amalgama, and is pure after the adhering quicksilver has been evaporated. The sand and heavier dust remaining on the launder is washed and treated in the same manner. The auriferous ores and loadstones, however, which rise from different mines, are calcined like silver ores, more or less, as the nature of their matrices will direct. Then they are ground and sifted; and the auriferous stuff thus prepared is put into heaps, exposed to the sunshine, and worked and turned about with tartarus and water for about three or four days. It requires no salt. Afterwards sulphur, and at last quicksilver, are added and mixed with it. There is no occasion for fire under the vessel in which it is triturated, except in winter; and two days after, though not dried, it is immediately carried to the washing-pit, and treated like the silver amalgama.

'This method of extracting gold and silver is so certain and safe, that, when other methods of amalgamation extract only one ounce of gold or silver, this produces three or four from the poorest ores in a shorter time, and with less expense.'

Soon after the process of amalgamation had been introduced in Peru, in the year 1588, a Spaniard of the name of Don Juan de Corduba, applied to the court of Vienna, offering to extract the silver from the ores, whether poor or rich, by the means of quicksilver, at a small expense, and within the course of eight or ten days. He was referred to baron Lewis de Hoyos, who laid before him various sorts of ore, from which he is reported to have actually extracted the gold and silver by his method. Upon this he was ordered to make a great experiment upon 20 cwt. of Kultenberg, in Bohemia. From the report of the celebrated Lazarus Erker, then upper bar-master at Kultenberg, and from papers sent in with the same, it appears that Corduba received for the above experiment 20 cwt. dried

mundick stuff of the stamps of five-eighths of an ounce of silver per cwt., which on the 21st of March he mixed with 17 cwt. of quicksilver, and left to macerate nineteen days. On straining 3 cwt. of the triturated stuff, he had no silver, nor could he recover above one-third of the quicksilver. He took afterwards half a cwt. of the calcined stamp stuff of Kultenberg, which he left to macerate ten days; and, straining it, he had but 1 cwt of silver, which was not full the tenth part of the real produce.

The quantity of mercury consumed in the process of amalgamation is thus described by baron Humboldt:—

'Mexico consumes annually upwards of 2,000,000 lbs. troy of mercury. In 1803 a very useful project was formed in Spain of supplying Mexico for several years, in order that, in the unforeseen case of a war, the amalgamation might not be impeded by the want of mercury; but this project (del requesto) shared the fate of many others which have never been executed. Before 1770, when the working of mines was far from being so considerable as at present, New Spain received no other mercury but that of Almaden and Huancavelica. The German mercury furnished by the Austrian government, of which the greatest part is from Idria, was only introduced into Mexico after the falling in of the subterraneous works of Huancavelica, at a time when the mine of Almaden was inundated in the greatest part of its works, and yielded a very inconsiderable produce. But in 1800, and 1802, this last mine was again in such a flourishing state, that it could alone have furnished more than 20,000 cwt. of mercury per annum, and there were sufficient grounds to conceive the hope of a termination of the necessity for recurring to German mercury, for the supply of Mexico and Peru. There have been years when 10,000 or 12,000 cwt. of this last mentioned mercury have been imported at Vera Cruz. Upon the whole, from 1762 to 1781, the amalgamation works of New Spain destroyed the enormous quantity of 25,124,200 lbs. troy, of which the value in America amounted to more than £2,400,000.

'When the price of mercury has progressively lowered, the working of the mines has gone on increasing. In 1590, under the viceroy Don Luis de Velasco II., a cwt. of mercury was sold in Mexico for £40 10*s*. But, in the eighteenth century, the value of this metal had diminished to such a degree, that in 1750 the court distributed it to the miners at £17 15*s*. Between 1767 and 1776, its price was £13 9*s*. per cwt. In 1777, under the administration of the minister Galvez, a royal decree fixed the price of the mercury of Almaden at £8 17*s*. 6*d*. and that of Germany at £13 13*s*. At Guanaxuato these two sorts of mercury are increased by the expensive carriage on the backs of mules, from 8*s*. 8*d*. to 10*s*. 10*d*. per cwt.

'The impartial distribution of mercury (el repartimiento del azogue) is of the greatest consequence to the prosperity of the mines of New Spain. Unfortunately, however, the viceroys and those persons who were about them, under the old government, were jealous of the right of administering this branch of the royal revenue. They knew very well that to distribute mercury, and especially that of Almaden, which is one-third cheaper than that of Idria, was to concede a favor; and in the colonies, as every where else, it is profitable to favor the richest and most powerful individuals. From this state of things, the poorest miners, those of Tasco, Temascaltepec, or Copala, could not procure mercury, when the great works of Guanaxuato and Real del Monte had it in abundance.

The following table proves the influence of the price of mercury on its consumption. The diminution of this price, and the freedom of trade with all the ports of Spain, have jointly contributed to the progress of mining.

Periods.	Price of a cwt. of mercury.	Total consumption of mercury.
	£. s. d.	
1762—1766	17 15 0	35,750 cwt.
1767—1771	13 9 0	42,000
1772—1777	13 9 0	53,000
1778—1782	8 17 6	59,000

'It was known in Mexico, in 1782, that China possesses mercury mines; and it was imagined that nearly 15,000 cwt. might be annually drawn from Canton. The viceroy Galvez sent thither a cargo of otter skins by way of exchange for the mercury; but this project, wise in itself, was badly executed. The Chinese mercury obtained from Canton and Manilla was impure, and contained a great deal of lead; and its price amounted to £17 6*s*. 8*d*. the cwt. Even at this price only a very small quantity could be procured. Since 1793 this important object has been totally lost sight of; yet it is deserving of the utmost attention, especially at a time when the Mexicans experience great difficulty in procuring mercury from the continent of Europe.

'From all the researches which I could make, the whole of Spanish America, namely, Mexico, Peru, Chili, and the kingdom of Buenos Ayres (for elsewhere the process of amalgamation is unknown), annually consume more than 25,000 cwt. of mercury, the price of which in the colonies amounts to more than £250,000 sterling. M. Heron de Villefosse, in an interesting table which contains the quantity of each metal extracted from the mines over the whole globe, estimates the mercury annually drawn from those of Europe at 36,000 cwt. From these data we find that mercury is, after cobalt, the rarest of all metals, and that it is even twice as rare as tin

'The following table indicates the quantity of mercury lost in the processes of amalgamation, used in different districts of mines, to extract the silver from the ore. A loss (perdida y consumo) of 100 lbs. of mercury is computed

	lbs. troy of silver.
In the mines of Guanaxuato, for about	65
In the mines of the intendancy of Guadalaxara	58
In the mines of Pachuca, Zacatecas, Sombrerete, Guadiana, Durango, Parral, Zichu, Tonala, Comanja, Zerralbo, Temextla, Alchichica, Tepeaca, Zimapan, Cairo, and Tlapa	53

In the mines of Chichiapa, Tetala, Tasco, Santa Theresa de Leiba y Banos, Ituquaro, Tehuistla, San Esteban dé Albukquerque, and Chiconasi 48
In the mines of Temascaltepec, Ayuteco, and Chautla de la Sal 44
In the mines of Zacualpa, San Luis Potosi, Guautla, Sultepec, and Tlapujahua . 42

'The government regulates the distribution (repartimiento) of silver, according to these data, and the quantity of silver annually extracted from the different districts of mines.

'The amalgamation of a cwt. of ores, which contain from three and a half to four ounces of silver, costs in Mexico, including the loss of mercury, from 4*s*. to 5*s*. M. Sonneschmidt calculates the loss of mercury at ten, twelve, or fourteen ounces for eight ounces of silver; and he reckons eight ounces of mercury consumed (azogue consumido), and from three to six ounces lost (azogue pirdido).

'From December 1801 till August 1804 Spain received from its colonies £23,250,094 in gold and silver, and £13,725,961 in agricultural produce. From 1788 to 1795 the total importation was only at an average, from £7,000,000 to £10,000,000 sterling per annum.

'The produce of the mines of Spanish America varies a seventh from year to year, or more than 310,000 lbs. troy of silver. We have estimated this produce for the Spanish and Portuguese colonies at 17,291 kilogrammes of gold, or 75,217 Castilian marcs, and at 795,581 kilogrammes or 4460 Castilian marcs of silver, which together are of the value of £9,400,000. Europe, Siberia, and America, furnish per annum 57,368 lbs. in gold, and 2,175,000 lbs. in silver, or to the value of £10,755,000.'

Mercury, when native, and enveloped in much earthy or other matter, from which it cannot be separated merely by washing, is distilled either by ascent or descent. When it is mineralised by sulphur, that is, when it is contained in cinnabar, some intermediate substance, as quicklime or iron, must be added in the distillation, to disengage it from the sulphur.

The rich ore of Almaden in Spain is a cinnabar, with which a calcareous stone happens to be so blended, that no addition is required to disengage the mercury from the sulphur. The distillation is there performed in a furnace consisting of two cavities, one of which is placed above another. The lower cavity is the fire-place, and contains the fuel, resting upon a grate, through the bars of which the air enters, maintains the fire, and passes into a chimney, placed at one side of the fire-place, immediately above the door through which fuel is to be introduced. The roof of this fire-place, which is vaulted and pierced with several holes, is also the floor of the upper cavity. Into this upper cavity, the mineral from which mercury is to be distilled is introduced through a door in one of the sides of the furnace. In the opposite wall of this cavity are eight openings, all at the same height. To each of these openings is adapted a pile of aludels connected and luted together, extending sixty feet in length. These aludels, which are earthen vessels open at each end, and wider in the middle than at either extremity, are supported upon an inclined terrace; and the aludel of each file, that is most distant from the furnace, terminates in a chamber built of bricks, which has two doors and two chimneys.

When the upper cavity is filled sufficiently with the mineral, a fire is made below, which is continued during twelve or fourteen hours. The heat is communicated through the holes of the vaulted roof of the fire-place to the mineral in the upper cavity, by which means the mercury is volatilised, and its vapor passes into the aludels, where much of it is condensed, and the rest is discharged into the brick-chamber, in which it circulates till it also is condensed. If any air or smoke passes through the aludels along with the vapor of the mercury, they escape through the two chimneys of the chamber. Three days after the operation, when the apparatus is sufficiently cooled, the aludels are unluted, the doors of the chamber opened, and the mercury is collected.

The metallurgical processes now resorted to in South America, for procuring the precious metals, are too important to be passed unnoticed. The conduct of the mines is thus described by baron Humboldt:—

The art of mining is daily improving, and the pupils of the School of Mines at Mexico gradually diffuse correct notions respecting the circulation of air in pits and galleries. Machines are beginning to be introduced, in place of the old method of carrying minerals and water on men's backs up stairs of a rapid ascent. In proportion as the mines of New Spain resemble more and more those of Europe, the miner's health will be less injured by the influence of the foul air, and the excessively prolonged efforts of muscular motion.

From 5000 to 6000 persons are employed in the amalgamation of the minerals, or the preparatory labor. A great number of these individuals pass their lives in walking barefoot over heaps of brayed metal, moistened and mixed with muriate of soda, sulphate of iron, and oxide of mercury, by the contact of the atmospheric air and the solar rays. It is a remarkable phenomenon to see these men enjoy the most perfect health. The physicians who practise in places where there are mines unanimously assert, that the nervous affections, which might be attributed to the effect of an absorption of oxide of mercury, very rarely occur. At Guanaxuato part of the inhabitants drink the very water in which the amalgamation has been purified (aqua de lavaderos) without feeling any injury from it. This fact has often struck Europeans not intimately acquainted with the principles of chemistry. The water is at first of a grayish-blue color, and contains in suspension black oxide of mercury, and small globules of native mercury and amalgamation of silver. This metallic mixture gradually precipitates, and the water becomes limpid. It can neither dissolve the oxide of mercury nor the muriate of mercury, which is one of the most insoluble salts we know. The mules are very fond of this water, because it contains a little muriate of soda in solution.

We have already said, that the labor of a

is entirely free throughout the kingdom of New Spain. No Indian or Mestizo can be compelled to devote himself to the working of mines. It is absolutely false, though the assertion has been repeated in works of the greatest estimation, that the court of Madrid sends out galley slaves to work in the gold and silver mines. The mines ot Siberia have been peopled by Russian malefactors, but in the Spanish colonies this species. of punishment has been fortunately unknown for centuries. The Mexican miner is tolerably well paid, as he earns at the least from £1 to £1. 4*s*. per week of six days, while the wages of laborers who work in the open air, hus bandmen for example, are 6*s*. 3*d*. on the central table-land, and 7*s*. 6*d*. near the coast. The miners, tenateros and faeneros, occupied in transporting the minerals to the plats (despachos), frequently gain more than 4*s*. 10*d*. per day of six hours. Honesty is by no means so common among the Mexican as among the German or Swedish miners; they make use of a thousand tricks to steal rich specimens of ores. As they are almost naked, and are searched on leaving the mine in the most indecent manner, they conceal small morsels of native silver, or red sulphuret and muriate of silver, in their hair, under their arm pits, and in their mouths. It is a most shocking spectacle to see in the large mines of Mexico, hundreds of workmen, among whom there are a great number of very respectable men, all compelled to allow themselves to be searched on leaving the shaft or level. A register is kept of the minerals found in the hair, in the mouth, or other parts of the miners' bodies. In the mine of Valenciana, at Guanaxuato, the value of these stolen minerals amounted between 1774 and 1787 to the sum of £63,000 sterling.

In the interior of the mines much care is employed in controlling the tenateros, by whom the ores are carried towards the shaft from the place of operation. At Valenciana, for example, they know to within a few pounds the quantity of work containing ore which daily goes out of the mine. I say, the work, for the rock is never there an object of extraction, and is employed to fill up the vacancies formed by the extraction of the minerals. At the plats of the great shafts, two chambers are dug in the wall, in each of which two persons (despachadores) are seated at a table, with a book before them containing the names of all the miners employed in the carriage. Two balances are suspended before them, near the counter. Each tenatero loaded with ores presents himself at the counter; and two persons stationed near the balances judge of the weight of this load by raising it lightly up. If the tenatero, who on the road has had time to estimate his load, believes it lighter than the despachador, he says nothing, because the error is advantageous to him; but on the other hand, if he believes the weight of the ore he carries in his bag to be greater than it is estimated, he demands that it should be weighed, and the weight which is thus determined is entered in the book of the despachador. From whatever part of the mine the tenatero comes, he is paid at the rate of one real de plata (6¼*d*.) for a load of 2¼ cwt., and one real and a half for a load of 3¼ cwt. per journey. There are some tenateros who perform in one day from eight to ten journeys, and their pay is regulated from the book of the despachador. This mode of reckoning is no doubt highly deserving of praise; and we cannot sufficiently admire the celerity, the order, and the silence with which they thus determine the weight of so many thousand quintals of ores, which are furnished by veins of six or eight fathoms in breadth, in a single day.

These ores, which are separated from the sterile rocks in the mine itself by the master miners (quebradores), undergo three sorts of preparation, viz. at the places for jigging or washing the ores, where women work; under the stamping mills; and under the tahonas or arastras. These tahonas are machines in which the work is ground under very hard stones, which have a rotatory motion, and weigh upwards of seven or eight cwt. They are not yet acquainted with washing with the tub (setz wäsche), nor washing on sleeping tables (tables dormantes) (liegende-heerde), or percussion (stosrheerde). The preparation under the stumps (mazos), or in the tahonas, to which I shall give the name of edge mills, on account of their resemblance to some oil and snuff mills, differs according as the ore is destined to be smelted or amalgamated. The mills properly belong only to this last process; however, very rich metallic grains called polvillos, which have passed through the trituration of the tahona, are also smelted.

The quantity of silver extracted from the ores, by means of mercury, is in the proportion of three and a half to one of that produced by smelting. This proportion is taken from the general table formed by the provincial treasuries, from the different districts of mines of New Spain. There are, however, some of these districts, for example those of Sombrerete and Zimapan, in which the produce from smelting exceeds that of amalgamation.

Silver (plata quintada) extracted from the Mines of New Spain, from the 1st January 1785 to the 31st of December 1789.

Provincial treasuries receiving the fifth.	Silver extracted by amalgamation.	Silver extracted by smelting.
Mexico . .	950,185	104,835
Zacatecas . .	1,031,360	173;631
Guanaxuato .	1,937,895	531,138
San Luis Potosi .	1,491,058	24,465
Durango . .	536,272	386,081
Guadalaxara .	405,357	103,615
Bolanos . .	336,355	27,614
Sombrerete . .	136,395	184,205
Zimapan . .	1,215	247,002
Pachuca . .	269,536	185,500
Rosario . .	477,134	191,368
Total in lbs. Troy	7,572,762	2,159,454

In times of peace amalgamation gains a gradual ascendancy over smelting, which is generally badly managed. As wood is becoming

yearly more scarce on the ridge of the Cordilleras, which is the most populous part, the diminution of the produce of smelting is very advantageous to the manufactories which require a great consumption of combustibles. In time of war the want of mercury arrests the progress of amalgamation, and compels the miner to endeavour to improve the process of smelting. M. Velasquez, the director-general of the mines, supposed even in 1797, before the discovery of the rich mines of Catorse, where there is scarcely any smelting, that of all the ores of New Spain two-fifths were smelted, and the other three-fifths amalgamated.'

The present mode of *smelting gold* at Villa Rica may now be adverted to. All the gold dust brought from the Comarca of Do Oiro Preto, or Villa Rica, comes first into the weighing room, where the escrivão da receita weighs it, and separates the fifth part from it as due to the king; and the escrivão da conferencia enters in the list the quantity of each owner, without and with the deduction. The parts belonging to the king are thrown together, mixed, and melted into large bars; but the four parts belonging to private individuals, into single smaller bars. For this purpose the gold-dust is put into a crucible of proportionate size, and, as soon as it begins to melt, it is kept there for some time with sublimate of mercury. When it appears to be perfectly melted, the metal is poured into a square iron mould, furnished with handles, in which it cools. These moulds are of very different sizes, containing from ten sitavas to an arroba of gold. The various combinations of the gold to be melted with iron, antimony, manganese, or arsenic, determine the time necessary to melt it. Gold which is more difficult to melt is mixed with a greater proportion of sublimate; this is particularly the case with that with which much iron is mingled; the workmen, by long experience, generally know the quantity of the addition which the gold of such mines requires. Very pure gold is perfectly melted in three hours The color of the gold smelted at Villa Rica is of very different hues, from the most beautiful gold-yellow to reddish copper-color, bright yellow, and even gray-yellow; a specimen of every shade is preserved. The gold bar when cut comes into the hands of the assayer, who determines the weight and fineness by the trial with sublimate: for this purpose he takes a piece from one end of the bar, and in difficult cases from both. In bars from well known mines the trial is made only with the touch-stone; for which are kept, on copper pins, the specimens from sixteen to twenty-four carats, each of which is divided into eight equal parts. The purest gold smelted at Villa Rica is of twenty-three carats and seven-eighths. The mines of Villa Rica generally produce gold from twenty to twenty-three carats; those of Sabará and Congontras de Sabará, from eighteen to nineteen carats; that from the Rio das Valhas near Sabará gives from nineteen to twenty. The gold of Cocaës and Inficionado is very pure, though not of a very fine yellow, but often pale or copper-colored. When the weight and fineness, and consequently the value, of the bar are determined and entered in the list, the Brazilian arms, the number of the list, the mark of the smelting-house, the date of the year, and the degree of fineness, are stamped upon it, and a printed ticket is given with the bar, which, besides all the above particulars, states the value in rees, the weight which the proprietor gave in gold-dust, and how much was deducted for the king. Without this instrument, signed by the officers of the smelting office, the bar, which is returned to the owner, cannot legally pass instead of coin. It is strictly prohibited to export it from the province of Minas without notice; because the royal mints are to repurchase the bars for their nominal value in ready money. But as an agio of ten per cent. is offered for the bars, even on the coasts of Brasil, this species of fraud is very common.

Arsenic, zaffre, and bismuth, are obtained generally from one ore, namely, that called cobalt. The arsenic of the ore is separated by roasting, and adheres to the internal surface of a chimney, which is extended horizontally about 200 or 300 feet in length, and in the sides of which are several doors, by means of which the arsenic, when the operation is finished, may be swept out and collected. These chimneys are generally bent in a zig zag direction that they may better retard and stop the arsenical flowers. These flowers are of various colors, white, gray, red, yellow, according to the quantity of sulphur or other impurity with which they happen to be mixed. They are afterwards purified by repeated sublimations, while some alkaline or earthy substances are added to detain the sulphur, and to assist the purification.

In the same roasting of the ore by which the arsenic is expelled, the bismuth, or at least the greatest part of this semi-metal which is contained in the ore, being very fusible, and having no disposition to unite with the regulus of cobalt, which remains in the ore, is secured by liquefaction.

The remaining part of the roasted ore consists chiefly of calx of regulus of cobalt, which not being volatile as the arsenic is, nor so easily fusible as bismuth is, has been neither volatilised nor melted. It contains also some bismuth, and a small quantity of arsenic, together with any silver or other fixed metal which happened to be contained in the ore. This roasted ore being reduced to a fine powder, and mixed with three or four times its weight of fine sand, is the powder called saffre or zaffre. Or the roasted ore is sometimes fused with about thrice its quantity of pure sand and as much pure potash, by which a blue glass called smalt is produced, and a metallic mass, called speiss, is collected at the bottom of the vessel in which the matters are fused. The metallic mass or speiss is composed of very different substances, according to the contents of the ore and the methods of treating it. The matters which it contains at different times are, nickel, regulus of cobalt, bismuth, arsenic, sulphur, copper, and silver. Bismuth is seldom procured from any other ores but that of cobalt. It might, however, be extracted from its proper ores, if a sufficient quantity of these were found, by the same method by which

it is obtained from cobalt, namely, liquefaction.

Before metallic ores are worked upon in the large way, it will be necessary to enquire what sort of metal, and what portion of it, is to be found in a determined quantity of the ore; to discover whether it will be worth while to extract it largely, and in what manner the process is to be conducted, so as to answer that purpose. The knowledge requisite for this is called the art of ASSAYING, and has already been briefly adverted to under that article.

The assaying of ores may be performed either in the dry or moist way; the first is the most ancient, and in many respects the most advantageous, and consequently still continues to be mostly used.

Assays are made either in crucibles under the blast of the bellows, or in tests under a muffle. The assay weights are always imaginary, sometimes an ounce represents a hundred weight on the large scale, and is subdivided into the same number of parts as that hundred weight is in the great; so that the contents of the ore obtained by the assay, shall accurately determine, by such relative proportion, the quantity to be expected from any weight of the ore on a larger scale.

In the lotting of the ores, care should be taken to have small portions from different specimens, which should be pulverised, and well mixed in an iron or brass mortar. The proper quantity of the ore is now taken, and if it contain either sulphur or arsenic, it is put into a crucible or test, and exposed to a moderate degree of heat, till no vapor arises from it; to assist this volatilisation, some add a small quantity of powdered charcoal. To assist the fusion of the ores, and to convert the extraneous matters connected with them into scoria, assayers use different kinds of fluxes. The most usual and efficacious materials for the composition of these are borax, tartar, nitre, sal ammoniac, common salt, glass, fluor-spar, charcoal powder, pitch, lime, litharge, &c., in different proportions. The crude of white flux consists of one part of nitre, and two of tartar, well mixed together.

The above crude flux detonates by means of kindled charcoal; and, if the detonation be effected in a mortar slightly covered, the smoke that rises unites with the alkalised nitre and the tartar, and renders it black.

Cornish reducing flux: 10 oz. of tartar, 3 oz. and 6 drachms of nitre, and 3 oz. and 1 drachm of borax; mixed well together. Cornish refining flux: deflagrate, and afterwards pulverise 2 parts of nitre and 1 part of tartar.

The above fluxes answer the purpose very well, provided the ores be deprived of all their sulphur, or if they contain much earthy matter, because in the latter case they unite with them and convert them into a thin glass; but, if any quantity of sulphur remain, these fluxes unite with it, and form a liver of sulphur, which has the power of destroying a portion of all the metals; consequently the assay, under such circumstances, must be very inaccurate. The principal difficulty in assaying appears to be in the appropriation of the proper fluxes to each particular ore; and it likewise appears that such a discriminating knowledge can only be acquired from an extensive practice, or from a knowledge of the chemical affinities and actions of different bodies upon each other.

In assaying, we are at liberty to use the most expensive materials to effect our purpose; hence the use of different saline fluxes; but, in the working at large, such expensive means cannot be applied, as by such processes the inferior metals would be too much enhanced in value, especially in working very pure ores. In consequence of which, in smelting works where the object is the production of metals in the great way, cheaper additions are used, such as limestone, feldt-spar, fluor-spar, quartz, sand, slate, and slags. These are to be chosen according to the different views of the operator, and the nature of the ores. Thus, iron ores, on account of the argillaceous earth they contain, require calcareous additions, and the copper ores, rather slags or vitrescent stones, than calcareous earth.

The mode of assaying ores for their particular metals, by the dry way, is deficient so far as relates to pointing out the different substances connected with them, because they are always destroyed by the process for obtaining the assay metal. The assay by the moist way is more correct, because the different substances can be accurately ascertained. The late celebrated Bergman first communicated this fact. It depends upon a knowledge of the chemical affinities of different bodies for each other: and must be varied according to the nature of the ore; it is very extensive in its application, and requires great patience and address in its execution. To describe the treatment of each variety of metallic ores would take up too much of our room; but, to give a general idea, we shall describe the procedure, both in the dry and the humid way, on one species of all the different ores.

To assay iron ores.—The ore must be roasted till the vapor ceases to rise. Take two assay quintals of it, and triturate them with one of fluor-spar, three-fourths of a quintal of powdered charcoal, and four quintals of decrepitated sea salt; this mixture is to be put into a crucible, lined on the inside with clay and powdered charcoal; a cover must be luted upon the crucible, and the crucible itself exposed to a violent fire for an hour, and, when it is cool, broken; when, if the operation has been well conducted, the iron will be found at the bottom of the crucible; to which must be added those metallic particles which may adhere to the scoria. The metallic particles so adhering may be separated by pulverising it in paper, and then attracting them with a magnet. If the ore should be in a calciform state, mixed with earths, the roasting of it previous to assaying, if not detrimental, is at least superfluous; if the earths should be of the argillaceous and siliceous kind, to half a quintal of them add of dry quick lime and fluor-spar of each one quintal and a quarter, reduced to powder, and mix them with one quarter of a quintal of powdered charcoal, covering the whole with one ounce of decrepitated common salt; and expose the luted crucible to a strong forge fire for an hour and a quarter; then let it gradually cool, and let the regulus be struck off

and weighed. If the ore contain calcareous earth, there will be no occasion to add quicklime; the proportion of the ingredients may be as follows, viz. one assay quintal of the ore, one of decrepitated sea salt, half a quintal of powdered charcoal, and one of fluor-spar, and the process conducted as above. There is a great difference in the reguli of iron; when the cold regulus is struck with a hammer and breaks, the iron is cold-short; if it break on being struck red-hot, it is called red-short; but if it resist the hammer both in its cold and ignited state it is good iron.

Humid assay of iron ore.—To assay the calciform ores, which do not contain much earthy or stony matter, they must be reduced to a fine powder, and dissolved in the marine acid, and precipitated by the Prussian alkali. A determinate quantity of the Prussian alkali must be tried previously, to ascertain the portion of iron which it will precipitate, and the estimate made accordingly. If the iron contain any considerable portion of zinc or manganese, the precipitate must be calcined to redness, and the calx treated with dephlogisticated nitrous acid, which will then take up only the calx of zinc; when this is separated, the calx should again be treated either with nitrous acid, with the addition of sugar, or with the acetous acid, which will dissolve the manganese, if any; the remaining calx of iron may then be dissolved by the marine acid, and precipitated by the mineral alkali, or it may be farther calcined, and then weighed.

Zinc ores.—Take the assay weight of roasted ore, and mix it well with an eighth part of charcoal dust; put it into a strong luted earthen retort, to which must be fitted a receiver; place the retort in a furnace, and raise the fire, and continue it in a violent heat for two hours; suffer it then to cool gradually, and the zinc will be found adhering to the neck of the retort in its metallic form.

In the humid way. Distil vitriolic acid over calamine to dryness; the residuum must be lixiviated in hot water; what remains undissolved is siliceous earth; to the solution add caustic volatile alkali, which precipitates the iron and argil, but keeps the zinc in solution. The precipitate must be re-dissolved in vitriolic acid, and the iron and argil separated.

Tin ores.—Mix a quintal of tin ore, previously washed, pulverised, and roasted, till no arsenical vapor rises, with half a quintal of calcined borax, and the same quantity of pulverised pitch; these are to be put into a crucible moistened with charcoal-dust and water, and the crucible placed in an air furnace. After the pitch is burnt, give a violent heat for a quarter of an hour, and on withdrawing the crucibles the regulus will be found at the bottom. If the ore be not well washed from earthy matters, a larger quantity of borax will be requisite, with some powdered glass; and if the ore contain iron, some alkaline salt may be added.

The assay of tin ores, in the liquid way, was looked upon as impracticable, till Bergman devised the following method, which is generally successful:—Let the tin ore be well separated from its stony matrix by well washing, and then reduced to the most subtile powder; digest it in concentrated sulphuric acid, in a strong heat for several hours; then, when cooled, add a small portion of concentrated marine acid, and suffer it to stand for an hour or two; then add water, and, when the solution is clear, pour it off, and precipitate it by fixed alkali; 131 grs. of this precipitate, well washed and dried, are equivalent to 100 of tin in its reguline state, if the precipitate consist of pure tin; but, if it contain copper or iron, it must be calcined in a red heat for an hour, and then digested in nitrous acid, which will take up the copper; and afterwards in marine acid which will separate the iron.

Lead ores.—As most of the lead ores contain either sulphur or arsenic they require to be well roasted. Take a quintal of roasted ore, with the same quantity of calcined borax, half a quintal of fine powdered glass, a quarter of a quintal of pitch, and as much clean iron-filings. Line the crucible with wetted charcoal dust, and put the mixture into the crucible, and place it before the bellows of a forge-fire. When it is red-hot, raise the fire for fifteen or twenty minutes; then withdraw the crucible and break it when cold.

In the humid way. Dissolve the ore by boiling it in dilute nitrous acid; the sulphur, insoluble stony parts, and calyx of iron, will remain. The iron may be separated by digestion in the marine acid, and the sulphur by digestion, in caustic fixed alkali. The nitrous solution contains the lead and silver, which should be precipitated by the mineral fixed alkalies and the precipitate well washed in cold water, dried, and weighed. Digest it in caustic volatile alkali, which will take up the calx of silver; the residuum, being again dried and weighed, gives the proportion of the calx of lead, 132 grs. of which are equal to 100 of lead in its metallic state. The difference of weight of the precipitate, before and after the application of the volatile alkali, gives the quantity of silver, 129 grs. of which are equal to 100 of silver in its metallic state.

Copper ores.—Take an exact troy ounce of the ore, previously pulverised, and calcine it well; stir it all the time with an iron rod, without removing it from the crucible; after the calcination add an equal quantity of borax, half the quantity of fusible glass, one-fourth the quantity of pitch, and a little charcoal dust; rub the inner surface of the crucible with a paste composed of charcoal dust, a little fine powdered clay, and water. Cover the mass with common salt, and put a lid on the crucible, which is to be placed in a furnace: the fire is to be raised gradually, till it burns briskly, and the crucible continued in it for half an hour, stirring the metal frequently with an iron rod; and, when the scoria which adheres to the rod appears clear, then the crucible must be taken out, and suffered to cool; after which it must be broken, and the regulus separated and weighed; this is called black copper, to refine which equal parts of common salt and nitre are to be well mixed together. The black copper is brought into fusion, and a tea-spoonful of the flux is thrown upon it, which is repeated three or four times, when the metal is poured into an ingot mould, and the button is found to be fine copper.

In the humid way. Make a solution of vitreous copper ore, in five times its weight of concentrated vitriolic acid, and boil it to dryness; add as much water as will dissolve the vitriol thus formed; to this solution add a clean bar of iron, which will precipitate the whole of the copper in its metallic form. If the solution be contaminated with iron, the copper must be redissolved in the same manner, and precipitated again. The sulphur may be separated by filtration.

Bismuth ores.—If the ore be mineralised by sulphur, or sulphur and iron, a previous roasting will be necessary. The strong ores require no roasting, but only to be reduced to a fine powder. Take the assay weight and mix it with half the quantity of calcined borax, and the same of pounded glass; line the crucible with charcoal; melt it as quickly as possible; and, when well done, take out the crucible, and let it cool gradually. The regulus will be found at the bottom.

In the humid way. Bismuth is easily soluble in nitrous acid or aqua-regia. Its solution is colorless, and is precipitable by the addition of pure water; 118 grs. of the precipitate from nitrous acid, well washed and dried, are equal to 100 of bismuth in its metallic form.

Antimonial ores.—Take a common crucible, bore a number of small holes in the bottom, and place it in another crucible a size smaller, luting them well together; then put the proper quantity of ore in small lumps into the upper crucible, and lute thereon a cover; place these vessels on a hearth, and surround them with stone about six inches distant from them; the intermediate space must be filled with ashes, so that the undermost crucible may be covered with them; but, upon the upper, charcoal must be laid, and the whole made red-hot by the assistance of hand-bellows. The antimony being of easy fusion is separated, and runs through the holes of the upper vessel into the inferior one, where it is collected.

Humid assay of arseniated antimony. Dissolve the ore in aqua-regia, both the regulus and arsenic remain in the solution, the sulphur is separated by filtration. If the solution be boiled with twice its weight of strong nitrous acid, the regulus of antimony will be precipitated, and the arsenic converted into an acid, which may be obtained by evaporation to dryness.

Manganese ore.—The regulus is obtained by mixing the calx or ore of manganese with pitch, making it into a ball, and putting it into a crucible, lined with charcoal powder one-tenth of an inch on the sides, and one-fourth of an inch at bottom; then filling the empty space with charcoal dust, covering the crucible with another inverted and luted on, and exposing it to the strongest heat of a forge for an hour or more.

In the humid way. The ores should be first well roasted to dephlogisticate the calx of manganese and iron, if any, and then treated with nitrous acid to dissolve the earths. The residuum should now be treated with nitrous acid and sugar, by which means a colorless solution of manganese will be obtained, and likewise of the iron, if any. Precipitate with the Prussian alkali, and digest the precipitate in pure water; the prussiate of manganese will be dissolved, whilst the prussiate of iron will remain undissolved.

Arsenical ores.—This assay is made by sublimation in close vessels. Beat the ore into small pieces, and put them into a matrass, which place in a sand-pot, with a proper degree of heat; the arsenic sublimes in this operation, and adheres to the upper part of the vessel, when it must be carefully collected with a view to ascertain its weight. Sometimes a single sublimation will not be sufficient, for the arsenic in many cases will melt with the ore, and prevent its total volatilisation, in which case it is better to perform the first sublimation with a moderate heat, and afterwards bruise the remainder again, and expose it to a stronger heat.

In the humid way. Digest the ore in marine acid, adding the nitrous by degrees to help the solution. The sulphur will be found on the filter; the arsenic will remain in the solution, and may be precipitated in its metallic form by zinc, adding spirit of wine to the solution.

Nickel ore.—The ores must be well roasted to expel the sulphur and arsenic; the greener the calx proves, during this torrefaction, the more it abounds in the nickel; but the redder it is, the more iron it contains. The proper quantity of this roasted ore is fused in an open crucible, with twice or thrice its weight of black flux, and the whole covered with common salt. By exposing the crucible to the strongest heat of a forge-fire, and making the fusion complete, a regulus will be produced. This regulus is not pure, but contains a portion of arsenic, cobalt, and iron. Of the first it may be deprived by a fresh calcination, with the addition of powdered charcoal; and of the second by scorification; but it is with difficulty that it is entirely freed from the iron.

By solution in nitrous acid it is freed from its sulphur; and, by adding water to the solution, bismuth, if any, may be precipitated: as may silver, if contained in it, by the marine acid; and copper, when any, by iron.

To separate cobalt from nickel, when the cobalt is in considerable quantity, drop a saturated solution of the roasted ore in nitrous acid into liquid volatile alkali; the cobaltic part is instantly re-dissolved, and assumes a garnet color; when filtered, a gray powder remains on the filter, which is the nickel. The cobalt may be precipitated from the volatile alkali by any acid.

A brief account of the most valuable metallic alloys must close this part of our subject. We may commence with a fusible metal. 4 oz. of bismuth, $2\frac{1}{2}$ oz. of lead, and $1\frac{1}{2}$ oz. of tin. Put the bismuth into a crucible, and, when it is melted, add the lead and tin. This will form an alloy fusible at the temperature of boiling water.

1 oz. of zinc, 1 oz. of bismuth, and 1 oz. of lead. This alloy is so very fusible that it will remain in a state of fusion if put on a sheet of paper, and held over the flame of a candle or lamp.

3 parts of lead, 2 parts of tin, and 5 parts of

bismuth, will form an alloy fusible at 197° Fahrenheit, peculiarly applicable to casting, or the taking of impressions from gems, seals, &c. In making casts with this and similar alloys, it is necessary to use the metal at as low a temperature as possible; otherwise, the water adhering to the things from which the casts are to be taken, forms vapor, and produces bubbles. The fused metal should be poured into a tea-cup, and allowed to cool, till just ready to set at the edges, when it must be poured into the mould. In taking impressions from gems, seals, &c., the fused alloy should be placed on paper or pasteboard, and stirred about till it has, by cooling, attained the consistence of paste, at which moment the die, gem, or seal, should be stamped on it, and a very sharp impression will then be obtained.

Bath metal is a mixture of 4½ oz. of zinc, with 1 lb. of brass.

Brass is composed of 4½ lbs. of copper, and 1½ lb. of zinc. But brass that is to be cast into plates, from which pans and kettles are to be made, and wire that is to be drawn, must, instead of using the zinc in a pure state, be composed of 56 lbs. of the finest calamine, or ore of zinc, and 34 lbs. of copper.

Old brass, which has frequently been exposed to the action of fire, when mixed with the copper and calamine, renders the brass far more ductile, and fitter for the making of fine wire, than it would be without it; but the German brass, particularly that of Nuremberg, is, when drawn into wire, said to be far preferable to any made in England for the strings of musical instruments.

Pinchbeck. 5 oz. of pure copper, and 1 oz. of zinc. The zinc must not be added till the copper is in a state of fusion. Some use only half this quantity of zinc, in which proportion the alloy is more easily worked, especially in the making of jewellery. Or 1 oz. of brass, and 2 oz. of copper, fused together under a coal of charcoal dust.

Prince's metal. 3 oz. of copper, and 1 oz. of zinc; or 8 oz. of brass, and 1 oz. of zinc. Or 4 oz. of copper, and 2 oz. of zinc. In this last the copper must be fused before the zinc is added. When they have combined, a very beautiful and useful alloy is formed, called prince Rupert's metal.

Bell-metal. 6 parts of copper, and 2 parts of tin. These proportions are the most approved, for bells, throughout Europe, and in China. In the union of the two metals the combination is so complete, that the specific gravity of the alloy is greater than that of the two metals in an uncombined state. Or 10 parts of copper, and 2 parts of tin. It may, in general, be observed, that a less proportion of tin is used for making church-bells than clock-bells: and that a little zinc is added for the bells of repeating-watches, and other small bells.

Tutania, or Britannia-metal. 4 oz. of plate brass, and 4 oz. of tin; when in fusion add 4 oz. of bismuth, and 4 oz. of regulus of antimony. This is the composition, or hardening, that is to be added at discretion to melted tin, until it has acquired the requisite degree of color and hardness; or melt together 2 lbs. of plate brass, 2 lbs. of tin, 2 lbs. of bismuth, 2 lbs. of regulus of antimony, 2 lbs. of a mixture of copper and arsenic, either by cementation or melting. This composition is to be added at discretion to melted tin; or 1 lb. of copper, 1 lb. of tin, and 2 lbs. of regulus of antimony, with or without a little bismuth; or 8 oz. of shruff brass, 2 lbs. of regulus of antimony, and 10 lbs. of tin.

German tutania. 2 drachms of copper, 1 oz. regulus of antimony, and 3 oz. of nitre.

Spanish tutania, 8 oz. of scrap-iron or steel, 1 lb. of antimony, and 3 oz. of nitre. The iron or steel must be heated to a white heat, and the antimony and nitre must be added in small portions. Melt and harden 1 lb. of tin with 2 oz. of this compound. Or melt together 4 oz. of antimony, 1 oz. of arsenic, and 2 lbs. of tin. The first of these Spanish alloys would be a beautiful metal if arsenic were added.

Engestroom tutania. 4 parts copper, 8 parts regulus of antimony, and 1 part bismuth. When added to 100 parts of tin, this compound will be ready for use.

Queen's metal. 4½ lbs. of tin, ½ lb. of bismuth, ½ lb. antimony, and ½ lb. lead. This alloy is used for the making of tea-pots, and other vessels, which are required to imitate silver. Or 100 lb. of tin, 8 lbs. regulus of antimony, 1 lb. bismuth, and 4lbs. copper.

White metal. 10 oz. of lead, 6 oz. of bismuth, and 4 drachms of regulus of antimony. Or 2 lbs. of regulus of antimony, 8 oz. of brass, and 10 oz. of tin.

Common hard white metal. 1 lb. of brass, 1½ oz. of zinc, and ½ oz. of tin.

Tombac. 16 lbs. of copper, 1lb. of tin, and 1 lb. of zinc.

Red tombac. 5½ lbs. of copper, and ½ lb. of zinc. The copper must be fused in the crucible before the zinc is added. This alloy is of a reddish color, and possesses more lustre, and is of greater durability than copper.

White tombac, copper, and arsenic, put together in a crucible and melted, covering the surface with muriate of soda, to prevent oxidation, will form a white brittle alloy.

Gun metal. 112 lbs. of Bristol brass, 14 lbs. zinc, and 7 lbs. block tin. Or 9 parts copper, and 1 part tin. The above compounds are those used in the manufacture of small and great brass guns, swivels, &c.

Blanched copper. 8 oz. of copper, and ½ oz. of neutral arsenical salt, fused together, under a flux composed of calcined borax, charcoal dust, and fine powder glass.

Specula of telescopes. 7 lbs. of copper, and when fused, add 3lbs. of zinc, and 4 lbs. of tin. These metals will combine and form a beautiful alloy of great lustre, and of a light yellow color, fitted to be made into specula for telescopes. Mr. Mudge used only copper and grain-tin, in the proportion of 2 lbs. to 14½ oz.

Kustitian's metal for tinning. To 1 lb. of malleable iron, at a white heat, add 5 oz. of regulus of antimony, and 24 lb. of the purest Molucca tin. This alloy polishes without the blue tint, and is free from lead or arsenic.

Metal for flute-key valves. 4 oz. of lead, and 5 oz. of antimony, fused in a crucible, and cast into a bar, forms an alloy of considerable hard

ness and lustre. It is used by flute manufacturers (when turned into small buttons in a lathe) for making valves to stop the key-holes of flutes.

Printers' types. 10 lbs. of lead, and 2 lbs. of antimony. The antimony must be thrown into the crucible when the lead is in a state of fusion. The antimony gives a hardness to the lead, without which the type would speedily be rendered useless in a printing-press. Different proportions of lead, copper, brass, and antimony, frequently constitute this metal. Every artist has his own proportions, so that the same composition cannot be obtained from different foundries; each boasts of the superiority of his own mixture.

Small types and stereotype plates. 9 lbs. of lead, and when melted, add 2 lbs. of antimony, and 1 lb. of bismuth. This alloy expands as it cools, and is therefore well suited for the formation of small printing types (particularly when many are cast together to form stereotype plates), as the whole of the mould is accurately filled with the alloy; consequently there can be no blemish in the letters. Or 8 parts lead, 2 parts antimony, and ½ part tin.

Common pewter. 7 lbs. of tin, 1 lb. of lead, 6 oz. of copper, and 2 oz. of zinc. The copper must be fused before the other ingredients are added. This combination of metals will form an alloy of great durability and tenacity; also of considerable lustre.

Best pewter. 100 parts tin, and 17 parts regulus of antimony.

Hard pewter. 12 lbs. of tin, 1 lb. regulus of antimony, and 4 oz. of copper.

Common solder. 2 lbs. of lead, and 1 lb. of tin. The lead must be melted before the tin is added. This alloy, when heated by a hot iron, and applied to the tinned iron with powdered rosin, acts as a cement or solder; it is also used to join lead pipes, &c.

Soft solder. 2 lbs. of tin, and 1 lb. of lead.

Solder for steel joints. 19 dwts. of fine silver, 1 dwt. copper, and 2 dwts. of brass, melted together under a coal of charcoal dust. This solder possesses several advantages over the usual zinc soda or brass, when employed in soldering cast steel, &c., as it fuses with less heat, and its whiteness has a better appearance than brass.

Silver solder for jewellers. 19 dwts. of fine silver, 1 dwt. copper, and 10 dwts. brass.

Silver solder for plating. 10 dwts. brass, and 1 oz. pure silver.

Gold solder. 12 dwts. of pure gold, 2 dwts. pure silver, and 4 dwts. copper.

Brass solder for iron. Thin plates of brass are to be melted between the pieces that are to be jointed. If the work be very fine, as when two leaves of a broken saw are to be brazed together, cover it with pulverised borax, melted with water, that it may incorporate with the brass powder which is added to it; the piece must be then exposed to the fire, without touching the coals, and heated till the brass is seen to run.

Bronze. 7 lbs. pure copper, 3 lbs. zinc, and 2 lbs. tin. The copper must be fused before the other ingredients are added. These metals, when combined, form the bronze, so much used both in ancient and modern times, in the formation of busts, medals, and statues.

According to Pliny, the metal used by the Romans for their statues, and for the plates on which they engraved inscriptions, was composed in the following manner:—They first melted a quantity of copper, into which they put one-third of its weight of old copper which had been long in use; to every 100lbs. weight of this mixture they added 12½ lbs. of an alloy, composed of equal parts of lead and tin.

Mock platina. Melt together 8 oz. of brass, and 5 oz. of zinc.

Useful alloy of gold with platinum. 7½ dr. pure gold, and ½ dr. platinum. The platinum must be added when the gold is perfectly melted. The two metals will combine intimately, forming an alloy rather whiter than pure gold, but remarkably ductile and elastic; it is also less perishable than pure gold, or jewellers' gold; but more readily fusible than that metal. These excellent qualities must render this alloy an object of great interest to workers in metals. For springs, where steel cannot be used, it will prove exceedingly advantageous. It is a curious circumstance that the alloy of gold and platinum is soluble in nitric acid, which does not act on either of the metals in a separate state. It is remarkable, too, that the alloy has very nearly the color of platinum, even when composed of eleven parts of gold to one of the former metal.

Ring gold. 6 dwts. 12 grs. Spanish copper, 3 dwts. 16 grs. fine silver, and 1 oz. gold coin.

Gold from 35s. to 40s. per ounce. 8 oz. 8 dwts. Spanish copper, 10 dwts. fine silver, and 1 oz. gold coin.

Manheim gold, or similor. 3¾ oz. copper, 1½ oz. of brass, and 15 grs. of pure tin.

Gliding metal. 4 parts of copper, 1 part of Bristol old brass, and 14 oz. of tin to every pound of copper.

For common jewellery. 3 parts of Copper, 1 part of Bristol old brass, and 4 oz. of tin to every pound of copper. If this alloy is for fine polishing, the tin may be omitted, and a mixture of antimony and lead substituted. Paler polishing metal is made by reducing the copper to two or to one part.

Yellow dipping metal. 2 parts of cheadle brass, 1 part of copper, with a little Bristol old brass, and ½ oz. of tin to every pound of copper. This alloy is almost of the color of gold coin. Cheadle brass is the darkest, and gives the metal a greenish hue. Old Bristol brass is pale and yellow. Or 1 lb. of copper, and 5 oz. of zinc. The copper should be tough cake, and not tile. When antimony is used, instead of tin, it should be in smaller quantity, or the metal will be brittle.

Imitation of silver. ¾ oz. of tin, and 1 lb. of copper, will make a pale bell-metal, which will roll and ring very near to sterling silver.

Of casting.—The casting of metal, after its preparation from the ore, is a most important part of the science of metallurgy.

The art of founding in metal, or casting, now occupies a space in our wants, which entitles it to considerable attention. If the Greeks, and after them the Romans, perfected it in as far as refers to the casting in brass and bronze, we have extended it more than they did, inasmuch as we have turned it to all the great features of general utility. Iron constitutes the grand staple in modern founding. See IRON MANUFACTURE.

The great abundance of this metal, with its consequent cheapness, together with the developments of chemistry, has, amongst us, opened to it a field, and created for it a demand, by which its operations may go on ad infinitum, and it is hoped with a success commensurate.

For composition of brass, see CHEMISTRY

The casting figures in brass is not much practised among the moderns at this time, although it was a good deal followed at the restoration of the arts in the fifteenth century. At that time brass works were had recourse to in the decoration of most buildings of any consideration; and, in order to supply the metal at little cost, several of the ancient edifices then existing were mutilated for the purpose. In Rome many of the vaultings to the temples were ornamented by having their lacunaria relieved by pateras and other decorations of brass or silver; these the popes of the times removed to compose the childish ornaments for their then erecting or newly consecrated Catholic churches. France, Germany, and England, at that time subject to the same caprice in religion as well as in the arts, adopted a similar style of decoration in their religious edifices, as numerous reliques still existing in tombs, shrines, screens, and other parts of their cathedrals and religious houses fully demonstrate. Amongst us certainly, and particularly after Henry VIII.'s separation from the church of Rome, such works were discontinued as Catholic and idolatrous. Elizabeth, proceeding in the reformation already commenced by her predecessor, not only destroyed the images, but the pictures also; and at the same time strictly forbad any thing of the kind to be admitted in future under the severest penalties. The rebellion in 1648, completed what the Reformation had begun. The fanatics of this time defaced whatever they could get at, that the former inquisition had spared; they tore down the brass from the monuments and screens, carried away the plate from the altars, broke the painted windows, and dilapidated the tombs of the saints, crying out in their work of spoliation, 'cursed be he that doeth the work of the Lord deceitfully.' After this, it would be vain to look in England for works in brass of any consideration, as little was spared but what was too remote for the Vandals of that period to get at. From this time, among us, a void or chaos existed and continued to exist in works of art, till a more enlightened policy began to blend itself, which happened about the close of the seventeenth century. But the effects of the persecution had been felt so much that the liberal arts had lost their practisers; hence the introduction of foreigners, and the consequent notion about our inability in works of taste; which is much too insipid and ridiculous at this time to need refutation.

We conclude with an account of our principal metalline exports, TIN, and COPPER :—

	Counties to which Exported.	Quantity of Tin Exported.	
		British Tin.	Foreign Tin.

METAMOR'PHOSE, *v. a.* } Fr. *metamorphoser*; Gr. *μεταμορφοω*. To change the form of a thing: transformation.
METAMOR'PHOSIS, *n. s.* }

Thou Julia, thou hast *metamorphosed* me;
Made me neglect my studies, lose my time.
Shakspeare.

They became degenerate and *metamorphosed* like Nebuchadnezzar, who, though he had the face of a man, had the heart of a beast. *Davies on Ireland.*

His whole oration stood upon a short narration, what was the causer of this *metamorphosis*. *Sidney.*

Obscene talk is grown so common, that one would think we were fallen into an age of *metamorphosis*, and that the brutes did not only poetically, but really speak. *Government of the Tongue.*

From such rude principles our form began,
And earth was *metamorphosed* into man. *Dryden.*

What! my noble colonel in *metamorphosis*? On what occasion are you transformed? *Id.*

Cowardice may be *metamorphosed* into prudence; intemperance into good-nature and good fellowship. *Pope.*

There are probable machines in epic poems, where the gods are no less actors than the men; but the less credible sort, such as *metamorphoses*, are far more rare. *Broome.*

METAMORPHOSIS is used for the mythological changes related by the ancient poets; upon which Ovid wrote fifteen books. Mythological metamorphoses were held to be of two kinds, apparent and real; thus that of Jupiter into a bull was only apparent; whereas that of Lycaon into a wolf was supposed to be real. Most of the ancient metamorphoses include some allegorical meaning, relating either to physics or morality: some authors are even of opinion that a great part of the ancient philosophy is couched under them; and lord Verulam and Dr. Hooke have attempted to unriddle several of them.

MET'APHOR, *n. s.* } Fr. *metaphore*; Gr. *μεταφορα*; *μετα*, trans, and *φερω*, I bear or carry. A trope or figure of speech whereby a word is applied to a use to which, in its original import, it cannot be put; or, as Dr. Johnson says, it is a simile comprised in a word.
METAPHOR'ICAL, *adj.* }
METAPHOR'IC. }

The words which were, do continue; the only difference is, that, whereas before they had a literal, they now have a *metaphorical* use. *Hooker.*

Some of the best interpreters therefore have taken this *metaphor* of light to imply the purity and perfect goodness of God. *Bp. Hall.*

The work of tragedy is on the passions, and in a dialogue; both of them abhor strong *metaphors*, in which the epopœa delights. *Dryden.*

The *metaphor* of laughing, applied to fields and meadows when they are in flower, or trees when they are in blossom, runs through all languages, which I have not observed of any other *metaphor*, excepting that of fire and burning when they are applied to love. *Addison.*

One died in *metaphor*, and one in song. *Pope.*

METAPHOR, in poetry. A metaphor differs from a simile in form only, not in substance: in a simile the two subjects are kept distinct in the expression, as well as in the thought; in a metaphor the two subjects are kept distinct in the thought only, not in the expression. For example, Homer compares a hero to a lion, and describes all the qualities of a lion that resemble those of the hero. The fundamental pleasure here, that of resemblance, belongs to the thought. An additional pleasure arises from the expression: the poet, by figuring his hero to be a lion, goes on to describe the lion in appearance, but in reality the hero; and his description is peculiarly beautiful, by expressing the virtues and qualities of the hero in new terms, which, properly speaking, belong not to him but to the lion. An allegory differs from a metaphor; and a figure of speech differs from both. A metaphor is an act of the imagination, figuring one thing to be another. An allegory requires no such operation, nor is one thing figured to be another: it consists in choosing a subject having properties or circumstances resembling those of the principal subject; and the former is described in such a manner as to represent the latter. The subject thus represented is kept out of view: we are left to discover it by reflection; and we are pleased with the discovery because it is our own work. In a figure of speech there is no fiction of the imagination employed, as in a metaphor; nor a representative subject introduced, as in an allegory. This figure, as its name implies, regards the expression only, not the thought; and it may be defined, the using a word in a sense different from what is proper to it. Thus youth, or the beginning of life, is expressed figuratively by the morning of life: morning is the beginning of the day; and in that view it is employed to signify the beginning of any other series, life especially, the progress of which is reckoned by days. The following particular rules, however, may here be laid down, as proper to be observed respecting metaphors:—No comparison ought to be made where the resemblance is either too strong or too faint. A metaphor, above all, ought to be short: it is difficult, for any time, to suppose a lively image of a thing to be what we know it is not; and, for that reason, a metaphor drawn out to any length, instead of illustrating or enlivening the principal subject, becomes disagreeable by overstraining the mind. In constructing a metaphor the writer ought to use such words only as are applicable literally to the imagined nature of his subject: figurative words ought carefully to be avoided; for such complicated figures, instead of setting the principal subject in a strong light, involve it in a cloud. The jumbling different metaphors in the same sentence, beginning with one metaphor and ending with another, commonly called a mixed metaphor, ought never to be indulged. It is improper to join different metaphors in the same period, even where they are preserved distinct; for, when the subject is imagined to be first one thing and then another, in the same period, without interval, the mind is distracted by the rapid transition. It is still worse to jumble together metaphorical and natural expression, so as that the period must be understood in part metaphorically, in part literally; for the imagination cannot follow, with sufficient ease, changes so sudden and unprepared.

MET'APHRASE, *n. s.* } Gr. *μεταφρασις*. A verbal translation from one language into another: a literal translator.
METAPHR'ASER, }

This translation is not so loose as paraphrase, nor so close as *metaphrase*. *Dryden.*

METAPHYSICS.

METAPHYSIC, *n. s.* ⎫ Fr. *metaphysique;*
METAPHYS'ICS, ⎬ Gr. *μεταφυσικη*. On-
METAPHYS'ICAL, *adj.* ⎬ tology; the doctrine
METAPHYSIC'IAN, *n. s.* ⎭ of the general affections of being: a term first used by Aristotle. See below. Metaphysical is used by Shakspeare for supernatural: a metaphysician is a person skilled in, or a student of, metaphysics.

Hie thee hither,
To chastise with the valour of my tongue
All that impedes thee from the golden round,
Which fate, and *metaphysical* aid, doth seem
To have crowned thee withal.
Shakspeare. Macbeth.

The mathematicks and the *metaphysicks*,
Fall to them as you find your stomach serves you.
Shakspeare.

Wherein the philosopher, and the superstitiously ignorant, are contrarily extreme: while the one seeks out natural causes of God's immediate and *metaphysical* works, the other ascribes ordinary effects to supernatural causes. *Bp. Hall.*

If sight be caused by intromission, or receiving in, the form of contrary species should be received confusedly together, which, how absurd it is, Aristotle shews in his *metaphysicks*. *Peacham.*

Call her the *metaphysicks* of her sex,
And say she tortures wits as quartans vex
Physicians. *Cleaveland.*

The *metaphysick's* but a puppet motion
That goes with screws, the notion of a notion,
The copy of a copy, and lame draught
Unnaturally taken from a thought. *Hudibras.*

See physick beg the Stagyrite's defence!
See *metaphysick* call for aid on sense!
Pope's Dunciad.

The topics of ontology, or *metaphysick*, are cause, effect, action, passion, identity, opposition, subject, adjunct, and sign. *Watts's Logick.*

METAPHYSICS. This term literally means after physics, and originated with Aristotle. After treating of physics, or rather what we should term natural history, he begins his next book with the Greek words *μετα τα φυσικα*, which we have joined together as one word—metaphysics. In the treatise of Aristotle, to which the above words are prefixed, he pretends to go beyond physics, to elevate the mind above corporeal objects, to fix it on the contemplation of spiritual things, and to enable it to judge of the principles of science by abstraction. The metaphysics of Aristotle were long a principal part of the learning of the schools, in which confusion was worse confounded. Johnson remarks, in his apposite manner, that what reason did not dictate, reason cannot explain; and this remark will apply in all its force to many unmeaning or absurd modes of expression. If we were at liberty to follow our own choice, we would rather discard the term metaphysics than attempt a definition of it. It is no longer the symbol of the absurdities that were formerly very gravely treated of under the imposing names of ontology and pneumatology; but it is yet so worthy of its origin and particular appropriation, that scarcely any two writers can be found who would agree respecting its import.

But, without attempting to define what is or what ought to be the import of the term, we purpose to give a brief view of the most distinguished metaphysical writers, from the period when the authority of Aristotle was shaken off, down to the present time; and to attempt an estimate of the reality and value of metaphysical knowledge.

What may be designated the modern metaphysics cannot be traced back farther than the fifteenth century,—that memorable period when an extraordinary impulse was given in Europe to the human mind, and commonly called the revival of learning. Down to that time, through the whole of the middle or dark ages, the doctrines of Aristotle were not only blindly received, but it was considered a kind of blasphemy to call them in question. There was now at last, however, a mental revolution, attended with extraordinary freedom and boldness towards received opinions and established authorities. Luther, the father of the Protestant Reformation, expresses himself with much decision concerning the futility of the Aristotelian doctrines. 'What does it contribute,' he asks, 'to the knowledge of things, to trifle and cavil in words conceived and prescribed by Aristotle concerning matter, form, motion, and time?' Nihil adjumenti ex ipso haberi posse non solùm ad theologiam seu sacras literas, verùm etiam ad ipsam naturalem philosophiam. Quid enim juvet ad rerum cognitionem, si de materiâ, formâ, motu, tempore, nugari et cavallari queas verbis ab Aristotele conceptis et præscriptis. The following passage to the same purpose is quoted by Bayle, article Luther, note H. H.: 'You will not persuade me that philosophy is that garrulity concerning matter, motion, infinity, place, vacuum, time:—things that we learn almost wholly from Aristotle, which avail nothing to the intellect, the affections, or moral conduct of men, but which are fit only to sow and spread contentions.' Non mihi persuadebitis, philosophiam esse garrulitatem illam de materiâ, formâ, motu, infinito, loco, vacuo, tempore, quæ ferè in Aristotele sola discimus, talia quæ nec intellectum, nec affectum, nec communes hominum mores quidquam juvent; tantùm contentionibus serendis seminandisque idonea. In another of the extracts made by Boyle from Luther, the latter says that he was very desirous if he had leisure of exposing the quackery of Aristotle. In his Colloquia Mensalia we are told that 'he hated Aristotle, and called the schoolmen sophistical locusts, caterpillars, frogs, and lice.' See *Jortin's Life of Erasmus.*

It cannot be fairly said that Luther affected to hate or despise what he would not be at the trouble of learning; for, according to the testimony of Melancthon and other competent witnesses, he possessed much mastery in scholastic learning, and was a strenuous partisan of the sect of Nominalists, or Terminists, concerning which some notice will be taken in a subsequent part. The opinion of Luther, so freely and boldly expressed, must have had much influence in bringing the scholastic metaphysics into neglect

and contempt among the Protestants. In this indeed, as in other important respects, the energy of the great reformer was counteracted by Melancthon, who favored to the utmost of his ability the Peripatetic jargon. 'The preservation of the Aristotelian philosophy in the Protestant colleges was chiefly owing to Melancthon, who wrote abridgments of most of its doctrines, which long prevailed in them. Et Melancthoni quidem præcipuè debetur conservatio philosophiæ Aristotelicæ in academiis Protestantium. Scripsit is compendia plerarumque disciplinarum philosophiæ Aristotelicæ, quæ in academiis diu regnârunt. Heineccii, Elem. Hist. Phil.

Another person who contributed not a little towards throwing off the yoke of the old philosophy, and establishing that intellectual independence which now began to display itself in several parts of Europe, was the famous or notorious Paracelsus. This daring innovator, who had so little reverence for antiquity that he would have made a bonfire of the writings of Aristotle, Hippocrates, and all the other old authors of any intellectual authority, was born at Einfidelen, Switzerland, in 1493, and was consequently ten years younger than Luther. Le Clerc, having quoted from Paracelsus the expression which designates the philosophy of Aristotle 'a wooden foundation,' adds, 'He ought to have attempted to lay a better; but, if he has not done this, he has at least, by discovering its weakness, invited his successors to look out for a firmer basis.'

A much better and more permanently influential man than Paracelsus was Ramus, born at Cuth in Picardy in 1515. He received his education in the college of Navarre, and his thesis on being admitted to the degree of M. A. was an attack on the doctrine of Aristotle; which occasioned a violent controversy, in consequence of which Ramus was prohibited from teaching; but he was in 1551 nominated to the regius professorship in the university of Paris, where he opposed Aristotle with invincible courage. The bold and persevering spirit with which Ramus, remarks Mr. Stewart, disputed in the university of Paris the authority of Aristotle, and the persecutions he incurred by this philosophical heresy, entitle him to an honorable distinction from the rest of his brethren. He was certainly a man of uncommon acuteness as well as eloquence, and placed in a very strong light some of the most vulnerable parts of the Aristotelian logic; without, however, exhibiting any marks of that deep sagacity which afterwards enabled Bacon, Descartes, and Locke, to strike at the very root of the system. His copious and not inelegant style as a writer recommended his innovations to those who were disgusted with the barbarism of the schools; while his avowed partiality for the reformed faith (to which he fell a martyr in the massacre of Paris) procured many proselytes to his opinions in all the Protestant countries of Europe. In England his logic had the honor, in an age of comparative light and refinement, to find an expounder and methodiser in the author of Paradise Lost; and in some of our northern universities, where it was very early introduced, it maintained its ground till it was supplanted by the logic of Locke. It has been justly said of Ramus, that, 'although he had a genius sufficient to shake the Aristotelian fabric, he was unable to substitute any thing more solid in its place;' but it ought not to be forgotten that even this praise, scanty as it may now appear, involves a large tribute to his merits as a philosophical reformer. Before human reason was able to advance, it was necessary that it should first be released from the weight of its fetters.'

How far human reason has been able to advance, in the metaphysical regions, we shall endeavour to ascertain in the proper place. It is certainly no small part of the merit of Ramus that he did not attempt to substitute any thing of his own for much that he objected to in Aristotle, whose chief folly, as well as that of many other metaphysicians, both before and after him, was in doing any thing whatever of the kind which he attempted. When men raise questions unsusceptible of solution, all that they can possibly write concerning them must be of the nature of a literary nuisance; and he performs the greatest service to the world who demolishes the babel-building and clears the whole away. It is said, by Montesquieu, that the only good book which the Spaniards have is the one which exposes the absurdity of all the rest. And we shall find, perhaps, that the best part of the best metaphysical book yet in existence is of this description.

Next in the order of time among the demolishers of the Aristotelian philosophy, but superior to all the others in intellectual power, stands the great lord Bacon, justly designated the father of experimental philosophy. It would now be idle to indulge in eulogial strains on the intellectual character of the author of Novum Organon. That he was a determined enemy to the sophistry and absurdity of the schools which had been so long dignified with the name of philosophy, and that he embraced every opportunity of exposing them, is well known to all who are acquainted with his writings. It is probable that the decided manner in which he expressed his opinion did more towards the exploding of the old philosophy than had been effected by the efforts of Luther, Paracelsus, Ramus, and all his predecessors, who aimed at its subversion. We must not forget, however, that, according to his own memorable words, 'time is the greatest of all innovators.' We are apt to ascribe too much to particular persons, and too little to the intellectual state of the world at the time when they appeared. There is no doubt, for instance, that Luther exerted a mighty influence on the opinions of his contemporaries; yet he is perhaps rather to be considered as the son than the father of the Reformation. So in reference to the school philosophy—its overthrow was owing to the progress of general knowledge in the slow course of time, rather than to any sudden creation of gigantic genius or influential intellect. The simultaneous attacks upon Aristotle in so many remote parts of Europe, in Germany, Italy, Switzerland, France, and England, proves that the general mind was now prepared to throw off the yoke.

'The merits of Bacon,' remarks Mr. Stewart, 'as the father of experimental philosophy, are so universally acknowledged, that it would be

superfluous to touch upon them here. The lights which he has struck out in various branches of the philosophy of mind have been much less attended to; although the whole scope and tenor of his speculations show that to this study his genius was far more strongly and happily turned than to that of the material world. It was not, as some seem to have imagined, by sagacious anticipations of particular discoveries afterwards to be made in physics, that his writings have had so powerful an influence in accelerating the advancement of that science. In the extent and accuracy of his physical knowledge he was inferior to many of his predecessors; but he surpassed them all in his knowledge of the laws, the resources, and the limits of the human understanding. The sanguine expectations with which he looked forwards to the future were founded solely on his confidence in the untried capacities of the mind; and on a conviction of the possibility of invigorating and guiding, by means of logical rules, those faculties which, in all our researches after truth, are the organs or instruments to be employed.

'Nor is it merely as a logician that Bacon is entitled to notice on the present occasion. It would be difficult to name another writer prior to Locke, whose works are enriched with so many just observations on the intellectual phenomena. Among these the most valuable relate to the laws of memory and of imagination; the latter of which subjects he seems to have studied with peculiar care. In one short and beautiful paragraph concerning Poetry, under which title may be comprehended all the various creations of this faculty, he has exhausted every thing that philosophy and good sense have ever yet had to offer, on what has been since called the beau ideal: a topic which has furnished occasion to so many over-refinements among the French critics, and to so much extravagance and mysticism in the cloud-capt metaphysics of the new German school. In considering imagination as connected with the nervous system more particularly as connected with that species of sympathy to which medical writers have given the name of imitation, he has suggested some very important hints which none of his successors have yet prosecuted; and has, at the same time, left an example of cautious enquiry, worthy to be studied by all who may attempt to investigate the laws regulating the union between mind and body. His illustration of the different classes of prejudices incident to human nature, is, in point of practical utility, at least equal to any thing on that head to be found in Locke; of whom it is impossible to forbear remarking, as a circumstance not easily explicable, that he should have resumed this important discussion without once mentioning the name of his great predecessor. The chief improvement made by Locke, in the farther prosecution of the argument, is the application of Hobbes's theory of association, to explain in what manner these prejudices are originally generated.

'In Bacon's scattered hints on topics connected with the philosophy of the mind, strictly so called, nothing is more remarkable than the precise and just ideas they display of the proper aim of this science. He had manifestly reflected much and successfully on the operations of his own understanding, and had studied, with uncommon sagacity, the intellectual characters of others. Of his reflections and observations on both subjects he has recorded many important results; and has in general stated them without the slightest reference to any physiological theory concerning their causes, or to any analogical explanations founded on the caprices of metaphorical language. If, on some occasions, he assumes the existence of animal spirits, as the medium of communication between soul and body, it must be remembered that this was then the universal belief of the learned; and that it was, at a much later period, not less confidently avowed by Locke. Nor ought it to be overlooked (I mention it to the credit of both authors) that in such instances the fact is commonly so stated, as to render it easy for the reader to detach it from the theory. As to the scholastic questions concerning the nature and essence of mind,—whether it be extended or unextended? whether it have any relation to space or time? or whether (as was contended by others) it exist in every ubi but in no place? Bacon has uniformly passed them over with silent contempt; and has probably contributed not less effectually to bring them into general discredit by this indirect intimation of his own opinion, than if he had descended to the ungrateful task of exposing their absurdity.

'While Bacon, however, so cautiously avoids these unprofitable discussions about the nature of mind, he decidedly states his conviction that the faculties of man differ not merely in degree, but in kind, from the instincts of the brutes. 'I do not therefore,' he observes on one occasion, 'approve of that confused and promiscuous method in which philosophers are accustomed to treat of pneumatology; as if the human soul ranked above those of brutes merely like the sun above the stars, or like gold above other metals.

'Among the various topics stated by Bacon, for the consideration of future logicians, he did not overlook (what may be justly regarded, in a practical view, as the most interesting of all logical problems) the question concerning the mutual influence of thought and of language on each other. 'Men believe,' says he, 'that their reason governs their words, but it often happens that words have power enough to re-act upon reason.' This aphorism may be considered as the text of by far the most valuable part of Locke's Essay,—that which relates to the imperfections and abuse of words; but it was not till within the last twenty years that its depth and importance were perceived in all their extent. I need scarcely say that I allude to the excellent Memoirs of M. Prevost, and of M. Degerando, on 'Signs considered in their connexion with the Intellectual Operations.' The anticipations formed by Bacon of that branch of modern logic which relates to universal grammar do no less honor to his sagacity. 'Grammar,' he observes, 'is of two kinds: the one literary, the other philoso-

phical. The former has for its object to trace the analogies running through the structure of a particular tongue, so as to facilitate its acquisition to a foreigner, or to enable him to speak it with correctness and purity. The latter directs the attention not to the analogies which words bear to words, but to the analogies which words bear to things,' or, as he afterwards explains himself more clearly, 'to language considered as the sensible portraiture or image of the mental processes.' In farther illustration of these hints he takes notice of the light which the different genius of different languages reflects on the characters and habits of those by whom they were respectively spoken. 'Thus,' says he, 'it is easy to perceive that the Greeks were addicted to the culture of the arts, the Romans engrossed with the conduct of affairs; inasmuch as the technical distinctions introduced in the progress of refinement require the aid of compounded words; while the real business of life stands in no need of so artificial a phraseology.' Ideas of this sort have, in the course of a very few years, already become common, and almost tritical; but how different was the case two centuries ago! It would be endless to particularise the original suggestions thrown out by Bacon on topics connected with the science of mind. The few passages of this sort already quoted are produced merely as specimens of the rest. They are by no means selected as the most important in his writings; but, as they happened to be those which left the strongest impression on my memory, I thought them as likely as any other to invite the curiosity of my readers to a careful examination of the rich mine from which they are extracted. His small volume of Essays, the best known and most popular of all his works, may be read from beginning to end in a few hours,—and yet, after the twentieth perusal, one seldom fails to remark in it something overlooked before. This, indeed, is characteristic of all Bacon's writings, and is only to be accounted for by the inexhaustible aliment they furnish to our own thoughts, and the sympathetic activity they impart to our torpid faculties.'

Most of the above remarks are as critically just as they are elegantly expressed. Perhaps a little more concentration and definiteness, or less diffuseness and vagueness of statement, could be wished. If we may express our idea of Bacon's peculiar excellence in the fewest possible words, it consists in pointing out in such a manner as at once to arrest attention and flash conviction the various sources or causes of human error. No author ever did more for sound philosophy, whether considered in reference to mind or to matter; consequently, in as far as the term metaphysics imports sound thinking and reasoning or real and useful knowledge, Bacon is entitled to rank among the first and highest of metaphysical philosophers; but, in the more limited and usual application of the expression, Hobbes is unquestionably to be considered as the father of the modern metaphysics, variously designated, with too much of assumption and pretension perhaps, the physiology of the mind, the philosophy of the human mind, the science of mind, intellectual philosophy, &c.

HOBBES, GASSENDI, AND DESCARTES.

The end of the sixteenth and beginning of the seventeenth century was pre-eminently the age of great men. Bacon, Galileo, Kepler, Hobbes, Milton, Gassendi, Descartes, and not a few others of kindred spirit, were contemporaries. Bacon was born in 1561, Hobbes in 1588, Gassendi in 1592, Descartes in 1596. 'The period when Hobbes began his literary career,' says Mr. Stewart, 'as well as the principal incidents of his life, were in a singular degree favorable to a mind like his; impatient of the yoke of authority and ambitious to attract attention, if not by solid and useful discoveries, at least by an ingenious defence of paradoxical tenets. After a residence of five years at Oxford, and a very extensive tour through France and Italy, he had the good fortune upon his return to England to be admitted into the intimacy and confidence of lord Bacon; a circumstance which we may presume contributed not a little to encourage the bold spirit of enquiry, and that aversion to scholastic learning, which characterise his writings.' 'It is very remarkable that Descartes should have thought so highly of the ethical principles of Hobbes as to pronounce him a much greater master of morality than of metaphysics. Mr. Addison, on the other hand, gives a decided preference (among all the books written by Hobbes) to his Treatise on Human Nature; and to his opinion on this point I most implicitly subscribe; including, however, in the same commendation some of his other philosophical essays on similar topics. They are the only part of his works which it is now possible to read with interest; and they every where evince in their author, even when he thinks most unsoundly himself, the power of setting his reader a thinking, which is one of the most unequivocal marks of original genius. They have plainly been studied with the utmost care both by Locke and Hume. To the former they have suggested some of his most important observations on the association of ideas, as well as much of the sophistry displayed in the first book of his Essay on the Origin of our Knowledge, and on the factitious nature of our moral principles; to the latter (among a variety of hints of less consequence) his theory concerning the nature of those established connexions among physical events which it is the business of the natural philosopher to ascertain, and the substance of his argument against the scholastic doctrine of general conceptions. It is from the work of Hobbes, too, that our later Necessitarians have borrowed the most formidable of those weapons with which they have combated the doctrine of moral liberty; and from the same source has been derived the leading idea which runs through the philological materialism of Mr. Horne Tooke. It is probable, indeed, that this last author borrowed it at second hand from a hint in Locke's Essay; but it is repeatedly stated by Hobbes, in the most explicit and confident terms. Of this idea (than which, in point of fact, nothing can be imagined more puerile and unsound) Mr. Tooke's etymologies, when he applies them to the solution of metaphysical questions, are little more than an ingenious expansion

adapted and levelled to the comprehension of the multitude. The speculations of Hobbes, how ever, concerning the theory of the understanding, do not seem to have been nearly so much attended to during his own life as some of his other doctrines, which, having a more immediate reference to human affairs, were better adapted to the unsettled and revolutionary spirit of the times. It is by these doctrines, chiefly, that his name has since become so memorable in the annals of modern literature; and although they now derive their whole interest from the extraordinary combination they exhibit of acuteness and subtlety with a dead palsy in the powers of taste and of moral sensibility, yet they will be found, on an attentive examination, to have had a far more extensive influence on the subsequent history, both of political and of ethical science, than any other publication of the same period.'

Much of the above quotation is very just, though somewhat debased with that metaphysicum odium so characteristic of the school of Reid, Oswald, and Beattie. Indeed Mr. Stewart writes more in the spirit of a metaphysical partisan, we had almost said of a persecutor, when treating of Hobbes, Gassendi, and sometimes too of Locke, than in the dispassionate temper of philosophy. In this respect Dr. Thomas Brown is a noble exception, or rather he is a striking contrast to the other moral professors of the Scottish universities. Instead of presenting the ethical and political principles of Hobbes to prejudice the reader against his writings in toto, in the manner of Mr. Stewart, Dr. Brown thus notices the philosopher of Malmesbury:—'I may now proceed farther back, to another philosopher of great eminence, whose name, unfortunately for its reputation, is associated more with his political and religious errors, than with his analytical investigations of the nature of the phenomena of thought. The author to whom I allude is Hobbes, without all question one of the most acute intellectual enquirers of the country and age in which he lived. As the physiology of the mind, in Britain at least, seemed at that time to be almost a new science, he was very generally complimented by his contemporary poets as the discoverer of a new land. Some very beautiful Latin verses, addressed to him, I quoted to you in a former lecture, in which it was said on occasion of his work on Human Nature, that the mind, which had before known all things, was now for the first time made known to itself.

Omnia hactenus
Quæ nosse potuit, nota jam primum est sibi.

and in which be was said in revealing the mind, to have performed a work next in divinity to that of creating it.

Divinum est opus
Animum creare, proximum huic ostendere.

By Cowley, who styles him 'the discoverer of the golden lands of new philosophy,' he is compared to Columbus, with this difference, that the world which that great navigator found was left by him rude and neglected, to the culture of future industry; while that which Hobbes discovered might be said to have been at once explored by him and civilised. The eloquence of his strong and perspicuous style, I may remark by the way, seems to have met with equal commendation from his poetical panegyrists. His style is thus described in some verses of Sheffield, duke of Buckingham:—

Clear as a beautiful transparent skin,
Which never hides the blood, yet holds it in;
Like a delicious stream it ever ran,
As smooth as woman, but as strong as man.'

The reader is now acquainted with some of the characteristic peculiarities of Hobbes's intellect; but no one can have an adequate conception of it without reading his writings. Mr. Stewart has awarded, though reluctantly, something of due praise to the treatise on Human Nature; which might have been entitled Multum in Parvo. It may be read, as Mr. Stewart remarks of Bacon's Essays, through in a few hours, and yet, after the twentieth perusal, one seldom fails to remark in it something overlooked before. It has not only the merit of setting the reader a thinking, as remarked by the above critic: we cannot read it, so as to enter into the author's meaning, without thinking; and it is impossible to give any thing like adequate attention, without understanding his meaning; for he excels not only in brevity, but in clearness and definiteness; expressing with a lucidness and rigorous precision, peculiarly his own, his meaning, his whole meaning, and nothing but his meaning. In this respect, indeed, he not only excels—he is a contrast to nearly all other metaphysicians, especially to Locke and Hume. Much of his other excellence is owing indeed to this; for, of all who have been aware of the connexion between words and ideas for better or for worse, none ever kept the nature of that connexion so steadily and so constantly in view. To such as have studied what he has said on this subject, the third book of Locke's Essay (unquestionably the best in the whole work) will seem mere prosing verbiage—a wood of words, to use one of Locke's own happiest expressions.

The following paragraph at the conclusion of Leviathan is strikingly characteristic of the author, and descriptive of his opinion respecting language as the medium of thought:—'There is nothing I distrust more than my diction: which nevertheless I am confident (excepting the mischances of the press) is not obscure. That I have neglected the ornament of quoting ancient poets, orators, and philosophers, contrary to the customs of late times, whether I have done well or ill in it, proceedeth from my judgment, grounded on many reasons. For, first, all truth of doctrine dependeth either upon reason or upon scripture; both which give credit to many, but never receive it from any writer. Secondly, the matters in question are not of fact but of right, wherein there is no place for witnesses. There is scarcely any of those old writers that contradicteth not sometimes, both himself and others, which makes their testimonies insufficient. Fourthly, such opinions as are taken only upon the credit of antiquity are not intrinsically the judgment of those that cite them, but words that pass (like gaping) from mouth to mouth. Fifthly, it is often with a fraudulent design that some

stick their corrupt doctrines with the cloves of other men's wit. Sixthly, I find not that the ancients they cite took it for an ornament to do the like with those that wrote before them. Seventhly, it is a proof of indigestion when Greek and Latin sentences come up again unchanged. Lastly, though I reverence those men of ancient times, that either have written truth perspicuously, or that have put us in a better way to find it out ourselves; yet to the antiquity itself I think nothing due: for, if we will reverence age, the present is the oldest time. If the antiquity of the writer is to be reverenced, I am not sure that generally they to whom such honor is given were more ancient when they wrote than I am when now writing: but, if it be well considered, the praise of ancient authors proceeds not from reverence for the dead, but from the competition and mutual envy of the living.'

Perhaps pedantry never received a more caustic application.. The following quotations from Leviathan, the most obnoxious of all the author's productions, are presented partly on account of their importance, and partly that the reader may be enabled to form a judgment as to the soundness of Mr. Stewart's criticism concerning the 'only part of Hobbes's works which it is now possible to read with interest.'

'When two names are joined together into an affirmation; as thus, a man is a living creature; if the latter name, living creature, signify all that the former name man signifies, then the affirmation is true; otherwise it is false. For true and false are attributes of speech, not of things. And where speech is not, there is neither truth nor falsehood. Error there may be, as when we expect that which shall not be, or suspect what has not been: but in neither case can a man be charged with untruth. Seeing then that truth consisteth in the right ordering of names in our affirmations, a man that seeketh precise truth had need to remember what every name he uses stands for, and to place it accordingly, else he will find himself entangled in words as a bird in lime-twigs; the more he struggles, the more belimed.'

'By this it appears how necessary it is for any man, that aspires to true knowledge, to examine the definitions of former authors, and either to correct them where they are negligently set down, or to make definitions for himself. For the errors of definitions multiply themselves as the reckoning proceeds; and lead men into absurdities, which at last they see, but cannot avoid without reckoning anew from the beginning; in which lies the foundation of their errors. Hence it happens that they who trust to books, do as they that cast up many little sums into a greater, without considering whether those little sums were rightly cast up or not; and at last finding the error visible, and not mistrusting their first grounds, know not which way to clear themselves, but spend time in fluttering over books; as birds that have entered by the chimney, finding themselves enclosed in a chamber, flutter at the false light of a glass-window, for want of wit to consider which way they came in. So that in the right definition of names lies the first use of speech, which is the acquisition of science; and in wrong or no definitions lies the first abuse, from which proceed false and senseless tenets; which make those men that take their instruction from the authority of books, and not from their own meditation, to be as much below the condition of ignorant men, as men endued with true science are above it. For, between true science and erroneous doctrines, ignorance is in the middle. Natural sense and imagination [conception] are not subject to absurdity. Nature itself cannot err: and as men abound in copiousness of language, so they become more wise or more foolish than ordinary. Nor is it possible without letters for any man to become remarkably wise, or (unless his memory be hurt by disease an or ill-constitution of organs) remarkably foolish. For words are wise men's counters, they do but reckon by them; but they are the money of fools that value them by the authority of an Aristotle, a Cicero, or a Thomas.

'The names of such things as affect us; that is, which please and displease us (because all men are not alike affected with the same thing, nor the same man at all times), are, in the common discourses of men, of inconstant signification. For, seeing all names are imposed to signify our conceptions, and all our affections are but conceptions, when we conceive the same things differently we can hardly avoid naming them differently. For though the nature of that which we conceive of be the same, yet the diversity of our conception of it in consequence of different constitutions of body, and prejudices of opinion, gives every thing a tincture of our different passions. And, therefore, in reasoning a man must take heed of words, which, besides what we imagine to be their own signification, have a signification also of the nature, disposition, and interest, of the speaker; such as the names of virtues and vices; for one man calls wisdom what another calls fear; what one calls cruelty another calls justice, &c.' *Leviathan*, the first part of chap. iv. of Speech.

'When a man reckons without the use of words, which may be done in particular things (as when upon the sight of any one thing we conjecture what was likely to have preceded, or is likely to follow upon it); if that which he thought likely to follow, follow not, or that which he thought likely to have preceded it, has not preceded it; this is called error, to which even the most sagacious men are subject. But when we reason in words of general signification, and fall upon a general inference which is false, though it be commonly called error, it is indeed absurdity or senseless speech. For error is but a deception, in presuming that somewhat is past or to come, of which, though it were not past or not to come, yet there was no impossibility discoverable. But when we make a general affirmation, unless it be a true one, the possibility of it is inconceivable. And words whereby we conceive nothing but the sound, are those we call absurd, insignificant, and nonsense.

'Man excels all other animals in the faculty of reason; but this privilege is alloyed by another, and that is the privilege of absurdity, to which no living creature is subject but man; and, of men, those are of all most subject to it who

profess philosophy. For it is most true that Cicero somewhere says of them, 'that there can be nothing so absurd, but may be found in the books of philosophers. And the reason is manifest, for there is not one of them that begins his ratiocinations from the definitions or explications of the names he is to employ, which is a method that has been used only in geometry, whose conclusions have, therefore, been made indisputable.

'The first cause of absurd conclusions I ascribe to the want of right method in not beginning their ratiocinations from definitions; that, is settled significations of their words; as if they could cast accounts without knowing the value of the numeral words one, two, and three. The second cause of absurd assertions I ascribe to the giving of the names of bodies to accidents [qualities], or of accidents to bodies. The third I ascribe to the giving of the names of the qualities of bodies without us to the accidents or affections of our own bodies, as they do that say the color is in the object, the sound is in the air, &c. The fourth to the giving of the names of bodies to names or speeches, as they do that say there are things universal. The fifth to the giving of the names of accidents to names and speeches, as they do that say the nature of a thing is its definition, a man's command is his will, &c. The sixth, to the use of metaphor, tropes, and other rhetorical figures, instead of proper words. For though it be lawful to say, in common speech, the way goeth or leadeth hither or thither, the proverb says this or that, whereas ways cannot go nor proverbs speak; yet in reckoning and seeking of truth such speeches are not to be admitted. The seventh, to names or words that signify nothing, but are taken up and learned by rote from the schools. To him that can avoid these things, it is not easy to fall into any absurdity, unless it be by the length of an account, wherein he may perhaps forget what went before. For all men by nature reason alike and well when they have good principles; for who is so stupid as both to mistake in geometry, and also to persist in it when another detects his error to him? They that have no science are in a better and nobler condition with their natural prudence, than men are who, by mis-reasoning or by trusting those that reason wrong, fall upon false and absurd general rules. For ignorance of causes and of rules does not set men so far out of their way, as relying on false rules, and taking for causes of what they aspire to those that are not so, but rather causes of the contrary.' *Leviathan*, chap. v. Of Reason and Science.

As remarked by Hume, Stewart, Addison, and others, the Treatise on Human Nature is unquestionably, as a whole, the best of all the works of Hobbes, and it contains little or nothing of those opinions of a theological and ethical nature which have been considered dangerous, and which have excited so much odium. We refer the reader to it, and will not attempt a syllabus of that which is so remarkable for brevity, that it might be designated a breviary or manual of intellectual analysis. The following quotations are given as a specimen of the author's manner to those who are not acquainted with his writings.

'Concerning these points, as the writings of men from antiquity downwards have still increased, so have doubts and controversies: and seeing true knowledge begetteth not doubt or controversy, it is manifest, from the present controversies, that they who have heretofore written thereof have not well understood their own subject. Harm I can do none, though I err no less than they; for I shall leave men but as they are, in doubt and dispute; but intending not to take my principle upon trust, but only to put men in mind of what they know already, or may know by their own experience, I hope to err the less; and, when I do, it must proceed from too hasty concluding, which I will endeavour as much as I can to avoid. On the other side, if reasoning aright win not consent, which may easily happen from them that, being confident of their own knowledge, weigh not what is said, the fault is not mine but theirs; for as it is my part to show my reasons, so it is theirs to bring attention.'

This is sufficiently haughty towards the courteous and gentle reader. In this respect indeed Hobbes is a remarkable contrast to Locke; which accounts, perhaps, for their opposite fate as to popularity. But, though the tone of the author of Human Nature is sufficiently confident and dogmatic, he is modest in reference to the merits of his own favorite study. He never attempts to magnify its importance by lofty language,—he never speaks of intellectual phenomena—of the philosophy of mind, &c., &c. As we shall have occasion in the sequel to remark, such metaphysical grandiloquentia did not come into existence till long after the days of Hobbes and Locke.

The following is the author's manner of entering upon what would now be termed the physiology of mind :—

'Having declared what I mean by the word conception, and other words equivalent thereunto, I proceed to conceptions themselves, to show their differences, their causes, and the manner of the production, so far as is necessary for this place. Originally all conceptions proceed from the action of the thing itself whereof it is the conception: now, when the action is present, the conception it produces is also called sense, and the thing by whose action the same is produced is called the object of the sense. By our several organs we have several conceptions of several qualities in the objects; for by sight we have a conception or image composed of color and figure, which is all the notice and knowledge the object imparts to us of its nature by the eye. By hearing we have a conception called sound, which is all the knowledge we have of the quality of the object from the ear. And so the rest of the senses are also conceptions of several qualities of their objects. Because the image in vision, consisting of color and shape, is the knowledge we have of the qualities of the object of that sense; it is no hard matter for a man to fall into this opinion, that the same color and shape are the very qualities themselves; and, for the same cause, that sound and noise are the qualities of the bell, or of the air. And this opinion hath been so long received that the contrary must needs appear a great paradox; and yet the intro

duction of species visible and intelligible (which is necessary to the maintenance of that opinion) passing to and from the object, is worse than any paradox, as being a plain impossibility. I shall therefore endeavour to make plain these points.

'That the subject wherein color and image are inherent is not the object or thing seen.

'That there is nothing without us (really) which we call an image or color.

'That the said image or color is but an appearance to us of the motion, agitation, or alteration, which the object worketh in the brain, or spirits, or some internal substance of the head.

'That, as in vision, so also in conceptions that arise from the other senses, the subject of their inherence is not the object, but the sentient.

'Every man has seen the sun and other visible objects by reflection in water and in glass; and this alone is sufficient for the conclusion that color and image may be where the thing seen is not. But because it may be said that though the image in the water is not in the object, but a mere appearance, yet there may be color really in the thing itself: I will urge further this experience, that frequently men see directly the same object double, as two candles for one, the colors and figures in two such images of the same thing cannot be inherent therein, because the thing seen cannot be in two places. One of these images therefore is not inherent in the object; consequently neither of them is absolutely inherent.

'As color is not inherent in the object, but an effect thereof upon us, so neither is sound in the thing we hear, but in ourselves. One manifest sign thereof is that, as a man may see, so also he may hear double or treble, by multiplication of echoes, which echoes are sounds as well as the original; and, not being in one and the same place, cannot be inherent in the body that causes them: nothing can make any thing which is not in itself: the clapper has no sound in it, but motion, and makes motion in the internal parts of the bell; so the bell has motion, and not sound, that imparts motion to the air; and the air hath motion, but not sound; the air imparts motion by the ear and nerve to the brain; and the brain hath motion, but not sound: from the brain it rebounds back into the nerves outward, and thence it becomes an appearance without, which we call sound. And, to proceed to the rest of the senses, it is apparent enough that the smell and taste of the same thing are not the same to every man; and therefore are not in the thing smelled or tasted, but in the men. So likewise the heat we feel from the fire is manifestly in us, and is quite different from what is in the fire; for our heat is pleasure or pain, according as it is great or moderate; but in the coal there is no such thing. Thus, as in vision, so also in conceptions that arise from other senses, the subject of their inherence is not in the object, but in the sentient. Hence also it follows that whatsoever accidents or qualities our senses make us think there are in the world, they are not actually there, but are appearances only: the things that really are in the world without us are those motions by which these appearances are caused. And this is the great deception of sense, which is also to be corrected by sense. for as sense tells me, when I see directly, that the color seems to be in the object; so also sense tells me, when I see by reflection, that color is not in the object.'

The reader may judge for himself how much more has been made of these matters, with all their laborious ingenuity, by Locke, Berkeley, Brown, and so many others.

The following is the germe of the famous doctrine of the association of ideas, so amply philosophised by Locke, Hartley, Hume, &c. &c.:—

'The succession of conceptions in the mind, one after another, may be casual and incoherent as in dreams for the most part; and it may be orderly, as when the former thought introduceth the latter; and this is discourse of the mind. But because discourse is commonly taken for the coherence and sequence of words, I will, to avoid equivocation, call it discussion. The cause of the coherence, or sequence of one conception to another, is their first coherence or sequence at that time when they are produced by sense. As, for example, from St. Andrew the mind runs to St. Peter, because their names are read together; from St. Peter to a stone for the same cause; from stone to foundation, because we see them together; and, for the same cause, from foundation to church; from church to people; and from people to tumult: and according to this example the mind may run almost from any thing to any thing. But as, in the sense, the conception of cause and effect may succeed one another, so may they after sense in the imagination. And for the most part they do so; the cause whereof is the desire of those who, having a conception of the end, have next to it a conception of the next means to that end: as when a man, from a thought of honor to which he has a desire, comes to the thought of wisdom, which is the next means thereunto; and from thence to study, which is the next means to wisdom.'

As the above is evidently the original of all that has since been advanced concerning the association of ideas, so with hardly any exception all that has been advanced on other topics by subsequent metaphysicians of greatest note may be found in a seminal or latent state in the writings of Hobbes. Mr. Stewart notices, as hardly consistent with gratitude or candor, that the only mention which Locke makes of the father of philosophic metaphysics is rather condemnatory than eulogial. It is probable, indeed, that Mr. Locke was afraid to commend even what was good in Hobbes, or to acknowledge that he had borrowed nearly all his ideas from one who was proscribed by common consent.

Before leaving the author of Leviathan, it may be proper to notice his theological and political heresies. They are unquestionably of a very objectionable nature. But it is much to be regretted that they have been much more met by violent clamor than by forcible reasoning; and it is also matter of regret that there has been so little discrimination in established or general opinion between what is good and what is bad in the philosopher of Malmesbury; who, according to Warburton, 'was the terror of the last age.'

'The press (continues the author of the Divine Legation) sweats with controversy, and every young churchman militant would try his arms in thundering at Hobbes's steel cap. 'Nor was the opposition to Hobbes,' remarks Mr. Dugald Stewart, 'confined to the clerical order, or to controversialists of his own times. The most eminent moralists and politicians of the eighteenth century may be ranked in the number of his antagonists; and even at the present moment scarcely does there appear a new publication on ethics or jurisprudence where a refutation of Hobbism is not to be found.' All this confesses at least that the object of so much animadversion and refutation is an intellectual leviathan. But Mr. Stewart might have added that there is scarcely one of the almost innumerable refutations which does justice to the hated author, or to his most hateful principles. We would give him fair play, all wicked and hateful as he is, and think the evil principles and reasonings of Hobbes might be opposed much more effectually and successfully than has yet been done. His atheism is not that of Epicurus or Spinoza. He was too acute a logician to blunder in the manner of either, and he was too honest to reason as his disciple Hume. He knew well how far to go, and when to stop. Nor can he be fairly charged with sophistry in argument. Grant his principle, and his reasoning is impregnable. He plainly and boldly propounds his opinion, which is unquestionably virtual atheism, morally and religiously considered; viz. that it is absurd to deny the being of a God, or first cause, but equally absurd to affirm that it is possible to know what he, or rather it is; because it is impossible to have an idea or image of God in the mind.

'Curiosity,' he says (Leviathan part I. chap. 2.), 'or love of the knowledge of causes, draws a man from consideration of the effect, to seek the cause; and again the cause of that cause; till of necessity he must come to this thought at last, that there is some cause whereof there is no former cause, but is eternal; which is it men call God. So that it is impossible to make any profound enquiry into natural causes without being inclined thereby to believe there is one God eternal; though they cannot have any idea of him in their mind answerable to his nature. For as a man that is born blind, hearing men talk of warming themselves by the fire, and being brought to warm himself by the same, may easily conceive and assure himself there is somewhat there which men call fire, and is the cause of the heat he feels, but cannot imagine what it is like nor have an idea of it in his mind, such as they have that see it; so also by the visible things of this world, and their admirable order, a man may conceive there is a cause of them which men call God, and yet not have an idea or image of him in his mind.'

This is perfectly true in the obvious sense of idea or image in reference to God; and yet it does not follow that we can have no knowledge of the intellectual or moral nature of God, which is what, however, Hobbes means. This is the root of all his ethical and political heresies; and we are convinced that it admits of the fullest and most satisfactory refutation. Indeed nothing can exhibit more strikingly the unsoundness of the author's theory of human knowledge, in connexion with idea or image as actually constituting it, than the above quotation. But we must not dwell longer on the topic in this place; it will probably come under consideration elsewhere.

Having said so much of Hobbes, it is not necessary to devote many sentences to his contemporary and friend Gassendi, who may be regarded as his metaphysical disciple, as he was an enthusiastic admirer of his writings as well as of those of Bacon. His metaphysical opinions, even when not adopted from Hobbes, coincided entirely with that of the latter philosopher, being derived from Epicurus. The intellectual character of Gassendi was certainly above mediocrity; but he was much inferior to Hobbes in acuteness, comprehension, and originality, and in some respects to his opponent Descartes, for he possessed less genius. Gibbon pronounces him le meilleur philosophe des litterateurs, et le meilleur litterateur des philosophes. 'His learning,' remarks Mr. Stewart 'was at once vast and accurate; and as a philosopher he is entitled to the praise of being one of the first who entered thoroughly into the spirit of the Baconian logic. But his inventive powers, which were probably not of the highest order, seem to have been either dissipated amidst the multiplicity of his literary pursuits, or laid asleep by his indefatigable labors, as a commentator and a compiler. From a writer of this class, new lights were not to be expected in the study of the human mind, and accordingly here he has done little or nothing, but to revive and repeat over the doctrines of the old Epicureans. His works amount to six large volumes in folio; but the substance of them might be compressed into a much smaller compass without any diminution of their value.'

The above critique is on the whole just; but the last sentence was a hazardous one for a critic to risk who is more remarkable for diffuseness than for condensation. It was said of Addison that, in his rules of criticism, he supplied weapons against himself. In voluminousness, as well as in other respects, Gassendi was a striking contrast to his friend Hobbes, who had certainly that attribute of a wise man, according to the old proverb, that he was sparing of his words. We are told by Sorbière that, having received De Corpore a few months before his death, Gassendi kissed it, adding, This book is indeed a little one, but it is full of matter, or rather it is all marrow. 'Thomas Hobbius Gassendo charissimus, cujus libellum De Corpore paucis ante obitum mensibus accipiens, osculatus est subjungens, mole quidem parvus est iste liber, verùm totus, ut opinor, medulla scatet.'

One quotation more from Mr. Stewart, respecting Gassendi, merits insertion. 'As Gassendi's attachment to the physical doctrines of Epicurus predisposed him to give an easier reception, than he might have otherwise done, to his opinions in metaphysics and in ethics; so his unqualified contempt for the hypothesis of the Vortices seems to have created in his mind an undue prejudice against the speculations of Descartes on all

other subjects. His objections to the argument by which Descartes has so triumphantly established the distinction between mind and matter, as separate and heterogeneous objects of human knowledge, must now appear, to every person capable of forming a judgment upon the question, altogether frivolous and puerile; amounting to nothing more than this, that all our knowledge is received by the channel of the external senses, insomuch that there is not a single object of the understanding which may not be ultimately analysed into sensible images; and of consequence that, when Descartes proposed to abstract from these images in studying the mind, he rejected the only materials out of which it is possible for our faculties to rear any superstructure. The sum of the whole matter is (to use his own language), that 'there is no real distinction between imagination and intellection;' meaning, by the former of these words, the power which the mind possesses of representing to itself the material objects and qualities it has previously received. It is evident that this conclusion coincides exactly with the tenets inculcated in England, at the same period, by his friend Hobbes, as well as with those revived at a later period by Diderot, Horne Tooke, and many other writers both French and English, who, while they were only repeating the exploded dogmas of Epicurus, fancied they were pursuing, with marvellous success, the new path struck out by the genius of Locke.

'It is worthy of remark that the argument employed by Gassendi against Descartes is copied almost verbatim from his own version of the account given by Diogenes Laertius of the sources of our knowledge, according to the principles of the Epicurean philosophy;—so very little is there of novelty in the consequences deduced by modern materialists from the scholastic proposition, Nihil est in intellectu quod non fuit prius in sensu. (There is nothing in the intellect or mind which was not previously in the sense or senses.) The same doctrine is very concisely and explicitly stated in a maxim formerly quoted from Montaigne, that 'The senses are the beginning and end of all our knowledge;' a maxim which Montaigne learned from his oracle Raymond de Sebonde: which, by the present race of French philosophers, is almost universally supposed to be sanctioned by the authority of Locke; and which, if true, would at once cut up by the roots, not only all metaphysics, but all ethics, and all religion, both natural and revealed.'

'A learned and profound writer has lately complained of the injustice done by the present age to Gassendi; in whose works, he asserts, may be found the whole of the doctrine commonly ascribed to Locke concerning the origin of our knowledge. The remark is certainly just, if restricted to Locke's doctrine as interpreted by the greater part of philosophers on the continent; but it is very wide of the truth if applied to it as now explained and modified by the most intelligent of his disciples in this country. The main scope, indeed, of Gassendi's argument against Descartes is to materialise that class of our ideas which the Lockeists, as well as the Cartesians, consider as the exclusive objects of the power of reflection; and to show that these ideas are ultimately resolvable into images or conceptions borrowed from things external. It is not, therefore, what is sound and valuable in this part of Locke's system, but the errors grafted on it in the comments of some of his followers, that can justly be said to have been borrowed from Gassendi. Nor has Gassendi the merit of originality even in these errors; for scarcely a remark on the subject occurs in his works but what is copied from the accounts transmitted to us of the Epicurean metaphysics.'

The author above referred to as complaining of the injustice done to Gassendi is De Gerando, Hist. Comp. des Systèmes, tome 1. His words are, 'Gassendi was the first author of the new philosophy of the human mind; for it is time to render to him that justice which he has hardly ever received even from his own countrymen. It is very remarkable that, in speaking of the new philosophy of the human mind, we always say the philosophy of Locke. D'Alembert and Condellac have authorised this expression, both ascribing to Locke exclusively the glory of this invention or discovery. Gassendi fut le premier auteur de la nouvelle philosophie de l'esprit humain; car il est tems de lui rendre, à cet égard, une justice qu'il n'a presque jamais obtenue de ses propres compatriotes. Il est très singulier en effet, qu'en parlant de la nouvelle philosophie de l'esprit humain, nous disions toujours la philosophie de Locke. D'Alembert et Condillac ont autorisé, cette expression, en rapportant l'un et l'autre à Locke exclusivement la gloire de cette invention.'

There is a portion of vague and incorrect statement in the above quotation from Mr. Stewart, which we shall have occasion to notice in a subsequent part; and it is now time to dismiss Gassendi.

Descartes will not detain us long; for all admit that, whatever were his other merits, he was a very unsound and wild metaphysician. It is true that he did much for free enquiry, and even his errors had, in some respects, considerable use. According to Condorcet he is better entitled, than any other individual, to be regarded as the father of that spirit of free enquiry which distinguishes modern Europe; and, according to Mr. Stewart, he may be considered the father of the experimental philosophy of the human mind. As the last mentioned critic is sufficiently disposed to admire and praise Descartes, and as his remarks are somewhat curious, if not always sound, we shall give a few quotations from him concerning 'the father of the experimental philosophy of the human mind.'

'The first steps of Descartes are peculiarly interesting and instructive; and it is these alone which merit our attention at present. As for the details of his system they are now curious only as exhibiting an amusing contrast to the extreme rigor of the principle whence the author sets out; a contrast so very striking as fully to justify the epigrammatic saying of D'Alembert, that Descartes began with doubting every thing, and ended in believing that he had left nothing unexplained.

'Among the various articles of common belief, which Descartes proposed to subject to a severe scrutiny, he enumerates particularly the conclusiveness of mathematical demonstration; the existence of God; the existence of the material world; and even the existence of his own body. The only thing that appeared to him certain and incontrovertible was his own existence; by which, he repeatedly reminds us, we are to understand merely the existence of his mind, abstracted from all consideration of the material organs connected with it. About every other proposition he conceived that doubts might reasonably be entertained; but to suppose the nonexistence of that which thinks, at the very moment it is conscious of thinking, appeared to him a contradiction in terms. From this single postulatum, accordingly, he took his departure; resolved to admit nothing as a philosophical truth which could not be deduced from it by a chain of logical reason. * * * Extravagant and hopeless as these preliminary steps must now appear, they had nevertheless an obvious tendency to direct the attention of the author in a singular degree to the phenomena of thought, and to train him to those habits of abstraction from external objects, which, to the bulk of mankind, are next to impossible. In this way he was led to perceive, with the evidence of consciousness, that the attributes of mind were still more clearly and distinctly knowable than those of matter; and that in studying the former, so far from attempting to explain them by analogies borrowed from the latter, our chief aim ought to be to banish, as much as possible, from the fancy, every analogy, and even every analogical expression, which, by inviting the attention abroad, might divert it from its proper business at home. In a word, that the only right method of philosophising on this subject was comprised in the stoical precept (understood in a sense somewhat different from that originally annexed to it), Nec te quæsiveris extra. A just conception of this rule, and a steady adherence to its spirit, constitutes the groundwork of what is properly called the experimental philosophy of the human mind. It is thus that all our facts relating to mind must be ascertained; and it is only on facts thus attested by our own consciousness that any just theory of mind can be reared.'

This sounds high or seems wonderful; but let us hear the sum of the whole matter. 'The glory, however, of having pointed out to his successors the true method of studying the theory of mind is almost all that can be claimed by Descartes in logical and metaphysical science. Many important hints indeed may be gleaned from his works; but on the whole he has added very little to our knowledge of human nature.' Alas! for the experimental philosophy of the human mind! But let us hear Mr. Stewart once more: 'Among the principal articles of the Cartesian philosophy, which are now incorporated with our prevailing and most accredited doctrines, the following seem to me to be chiefly entitled to notice.

'1. His luminous exposition of the common logical error of attempting to define words which express notions too simple to admit of analysis. Mr. Locke claims this improvement as entirely his own; but the merit of it unquestionably belongs to Descartes, although it must be owned that he has not always sufficiently attended to it in his own researches.'

There is here a two-fold error in awarding unmerited praise to Descartes, who was not the first to remonstrate against attempting impossible definition; and in applying unmerited censure to Locke, who does not claim what Mr. Stewart terms an improvement as entirely his own. His words are, 'The names of simple ideas are not capable of any definition, the names of complex ideas are.—It has not, that I know, been yet observed by any body, what words are and what words are not capable of being defined.' This admits of a very different interpretation from that put upon it by the critic; and the modesty of Mr. Locke, in saying, 'it has not that I know been yet observed by any body,' ought to have protected him from the charge of setting up a false claim. But let Mr. Stewart proceed with the merits of the father of the experimental philosophy of the human mind.

'2. His observations on the different classes of our prejudices, particularly in the errors to which we are liable in consequence of a careless use of language as the instrument of thought. The greater part of these observations, if not the whole, had been previously hinted at by Bacon; but they are expressed by Descartes with greater simplicity, and in a style better adapted to the taste of the present age.'

Here, liberal as the critic in general is of praise to the English father of experimental philosophy, he would abstract some merit from him to bestow it on the French father of the experimental philosophy of mind. But if Bacon failed, did not Hobbes point out with sufficient precision and simplicity the different classes of prejudice; particularly on the errors to which we are liable in consequence of a careless use of language as the instrument of thought?

'3. The paramount and indisputable authority, which, in all our reasonings concerning the human mind, he ascribes to the evidence of consciousness.'

Has not Hobbes ascribed as much to consciousness as Descartes? and was not the former prior in time to the latter?

'4. The most important, however, of all his improvements in metaphysics, is the distinction which he has so clearly and so strongly drawn between the primary and the secondary qualities of matter. This distinction was not unknown to some of the ancient schools of philosophy in Greece; but it was afterwards rejected by Aristotle and by the schoolmen; it was reserved for Descartes to place it in such a light, as (with the exception of a very few sceptical or rather paradoxical theorists) to unite the opinions of all succeeding enquirers. It may be proper to remark that the epithets primary and secondary now universally employed to mark the distinction in question, were first introduced by Locke; a circumstance which may have contributed to throw into the shade the merits of those enquirers who had previously struck into the same path.'

We shall examine the merits of this boasted

distinction, when we come to Dr. Brown's Lectures. In the mean time it is evident, from Mr. Stewart's own showing, that it was only a revival of an old opinion, which he has shown in the case of Gassendi is no great matter. But who has written more simply, more clearly, more intelligibly, concerning the point in question than Hobbes? We refer the reader to the quotation made from the Treatise on Human Nature.

Among the other vagaries of Descartes was his notable one in assigning the pineal gland, or conarium, as the principal seat of the soul, because, among the different parts of the brain, this was the only one he could find, being single and central, that was fitted for the habitation of a being, of which he conceived unity and individuality to be essential and obvious attributes. This ludicrous notion is wittily alluded to in the Alma of Prior—

> —— Here Matthew said
> Alma in verse, in prose the mind
> By Aristotle's pen defined,
> Throughout the body squat or tall
> Is bonâ fide all in all;
> And yet slap-dash is all again
> In every sinew, nerve, and vein;
> Runs here and there like Hamlet's ghost,
> While every where she rules the roast.
> This system, Richard, we are told
> The men of Oxford firmly hold;
> The Cambridge wits, you know, deny
> With ipse dixit to comply—
> They say (for in good truth they speak
> With small respect of that old Greek)
> That, putting all his words together,
> 'Tis three blue beans in one blue bladder;
> Alma, they strenuously maintain,
> Sits cock-horse on her throne the brain;
> And from that seat of thought dispenses
> Her sovereign pleasure to the senses, &c. &c.

Perhaps the reader, notwithstanding all the strenuous criticism on the merits of Descartes to which we have adverted, will be disposed to say with Prior—

> That, putting all his words together,
> 'Tis three blue beans in one blue bladder.

In connexion with Descartes some slight notice is due to his disciple Malebranche, who commenced his literary career about twenty-five years after the death of the former; and who, with all his Platonic mysticism, possessed uncommon genius, and wrote with great eloquence. His Search of Truth, La Recherche de la Verité, is a charming work, concerning which the reader is ready to exclaim, in the words of Cowper, in reference to his country, 'with all thy faults I love thee still.' It contains a wonderful mixture of beauty and deformity, of truth and error, wisdom and folly.

La Recherche de la Verité is well charactensed by Dr. Brown, in his thirtieth lecture, as 'a work which is distinguished by much eloquence, and by many profound remarks on the sources of human error, but which is itself an example in the great system which it supports, of error as striking as any of those which it eloquently and profoundly discusses. It is truly unfortunate for his reputation, as a philosopher, that these discussions do not form a separate work, but are blended with his own erroneous system, the outline of which every one knows too well to think of studying its details. All that is necessary to give him his just reputation is merely that he should have written less. He is chiefly known at present as the author of a very absurd hypothesis. He would have been known and studied, and honored, as a very acute observer of our nature, if he had never composed those parts of his work, to which, probably, when he thought of other generations, he looked forward as to the basis of his philosophic fame. His hypothesis, as many of you probably know, is, that we perceive not objects themselves, but the ideas of them which are in God.'

Locke, Hartley, Berkeley, and others, have borrowed freely from Malebranche; the first his notion of habits; the second, his theory of vibrations; the third (probably at least), his ideal theory. Berkeley had once a short interview with Malebranche (and never, perhaps, were there two men better entitled to be designated twin spirits), when the conversation turned, as might be expected, on the non-existence of matter. Malebranche, who had an inflammation on his lungs, and whom Berkeley found preparing a medicine in a small pipkin, in his cell, exerted his voice so violently in the heat of dispute, that he increased his disorder, which carried him off a few days after, 1715, in the seventy-seventh year of his age.

Having mentioned Berkely, as a kin, metaphysically considered, to Malebranche, it is sufficient to say of him in the words of Dr. Brown, already quoted, 'that he is now chiefly known as the author of a very absurd hypothesis, viz that material objects have no other existence than in the mind. His writings display much acuteness and genius, and contain many important remarks, though they are now little read, and scarcely ever alluded to; for, as Warburton justly remarks (and the remark is not the less true and forcible for being applicable also to his own writings), 'fanciful hypotheses, when grown stale, are the most nauseous of all things.'

LOCKE AND LEIBNITZ.

These names are prominently identified with the metaphysical history of the eighteenth century. To connect Locke, Leibnitz, and their most eminent contemporaries, with their yet more eminent predecessors, it may be remarked, that Bacon died in 1626, Kepler in 1630, Galileo in 1642, Descartes in 1650, Gassendi in 1655, old Hobbes, as he is sometimes designated (for he lived ninety years in the world), in 1679. Locke was born in 1632, Malebranche in 1638, Newton in 1642, Leibnitz in 1646, Clarke in 1675. Locke is prior to Leibnitz both in the order of time and in metaphysical rank; but as it is not necessary to say much of the latter, and as he properly classes with Cudworth, who was prior in time to Locke, we shall dispose of the German metaphysician first.

Leibnitz, the rival of Newton, was unquestionably a very extraordinary man; but, metaphysically considered, he is now like Descartes, Malebranche, and Berkeley, chiefly known as the author of some very wild hypotheses. The following

quotation from Mr. Stewart has the merit of more than usual simplicity and brevity, especially in his Dissertations, establishing a general view of Metaphysical, Ethical, and Political Philosophy. 'The opinion of Leibnitz concerning the origin of our knowledge, though expressed in a different phraseology, agrees in the most essential points with the innate ideas of the Cartesians; but it approaches still more nearly to some of the mystical speculations of Plato. The very exact coincidence between the language of Leibnitz on this question and that of his contemporary Cudworth, whose mind, like his own, was deeply tinctured with the Platonic metaphysics, is not unworthy of notice as an historical fact. 'The seeds of our acquired knowledge,' says Leibnitz, 'or, in other words, our ideas, and the eternal truths which are derived from them, are contained in the mind itself; nor is this wonderful, since we know, by our own consciousness, that we possess within ourselves the ideas of existence, of unity, of substance, of action, and other ideas of a similar nature.' To the same purpose we are told by Cudworth, that 'the mind contains in itself naturally (as the future plant or tree is contained in the seed) general notions of all things which unfold and discover themselves as occasions invite, and proper circumstances occur.' The metaphysical theories, to the establishment of which Leibnitz chiefly directed the force of his genius, are the doctrine of pre-established harmony, and the scheme of optimism, as new-modelled by himself. According to the system of pre-established harmony, the human mind and human body are two independent, but constantly correspondent, machines; adjusted to each other like two unconnected clocks, so constructed that, at the same instant, the one should point the hour, and the other strike it. 'I cannot help coming into this notion,' says Leibnitz, in his Essay entitled Theodicæa, 'that God created the soul in such a manner at first, that it should represent within itself all the simultaneous changes in the body; and that he has made the body also in such a manner, as that it must of itself do what the soul wills; so that the laws which make the thoughts of the soul follow each other in regular succession must produce images which shall be co-incident with the impressions made by external objects upon our organs of sense; while the laws by which the motions of the body follow each other are likewise so coincident with the thoughts of the soul, as to give to our volitions and actions the very same appearance as if the latter were really the natural and necessary consequences of the former. Every thing goes on in the soul as if it had no body; and every thing goes on in the body as if it had no soul.'

We will not trouble our readers with more of this philosophic folly. It is hardly possible to avoid the suspicion, entertained by Le Clerc and others, that the opinions maintained by Leibnitz were not his real sentiments; but mere moot displays of ingenuity, if not a sham defence of religious and moral principles, for the purpose of more effectually delivering them over to the enemy. Indeed Gibbon unhesitatingly asserts, that, 'in his defence of the attributes and providence of the Deity, he was suspected of a secret correspondence with his adversary Bayle.' The evidence contained in a letter of Leibnitz to Pfaffins, professor of theology in the university of Tubingen, seems conclusive that he was at least only in sport (a very wanton if not wicked kind of sport, however) on subjects, which are either all-important or of no importance. In the letter alluded to, Leibnitz says, 'It is exactly as you write concerning my Theodicæa; and I wonder that no one should have hitherto discovered my design. For it is not the part of philosophers always to treat subjects seriously; who in framing hypotheses, as you justly remark, try the force of their genius. You who are a theologian, in refuting errors, act or play the theologian.' Ita prorsus est vir summe reverende, uti scribis, de Theodicæa mea. Rem acu tetigisti; et miror, neminem hactenus fuisse, qui sensum hunc meum senserit. Neque enim philosophorum est rem serio semper agere; qui in fingendis hypothesibus, uti bene mones, ingenii sui vires experiuntur. Tu qui theologus, in refutandis erroribus, theologium agis.

The manner in which Mr. Stewart attempts to nullify this evidence is curious. In reply to this, it is observed by the learned editor of Leibnitz's works, that 'it is much more probable that Leibnitz should have expressed himself on this occasion in jocular and ironical terms, than that he should have wasted so much ingenuity and learning in support of an hypothesis to which he attached no faith whatever; an hypothesis (he might have added) with which the whole principles of his philosophy are systematically, and, as he conceived, mathematically connected.'

Upon this hypothesis of jocularity, or irony, what evidence of words may not be evaded? As to probability and improbability we think it very likely that Leibnitz, in his sober serious moments, considered the greater part of his philosophical or mathematical principles, such as the sufficient reason, the law of continuity, negative quantities (concerning which his language is truly marvellous), &c. &c., in much the same light as his theory of the origin of knowledge, of pre-established harmony, and of optimism. The fact is, as we have intimated in the article MATHEMATICS, there is an intimate connexion between mathematical and metaphysical absurdity; and therefore the profoundest mathematicians are usually the wildest metaphysicians; such as Descartes and Leibnitz; nor are Newton and Clarke exceptions to the general rule. Thus Newton, for example, expresses himself concerning what it would have been more a proof of wisdom to be silent than to darken counsel by words without knowledge. Æternus est infinitus, omnipotens, et omnisciens; id est, durat ab æterno ad æternum, et adest ab infinito in infinitum. Non est æternitas et infinitas, sed æternus et infinitus; non est duratio et spatium, sed durat et adest. Durat semper et adest ubique, et existendo semper et ubique durationem et spatium constituit. Thus translated by Dr. Clarke, 'God is eternal and infinite, omnipotent and omniscient; that is, he endures from everlasting to everlasting, and is present from infinity to infinity. He is not eternity or infinity, but eternal and infinite. He is not duration or space, bu

he endures and is present. He endures always, and is present everywhere; and, by existing always and everywhere, constitutes duration and space.' It is on this notable definition that Clarke's celebrated à priori argument for the existence of God is founded. He argues that as immensity and eternity (which force themselves on our belief as necessary to existence), are not substances but attributes, the immense and eternal Being whose attributes they are must exist of necessity also. 'These,' says Dr. Reid, 'are the speculations of men of superior genius; but whether they be as solid as they are sublime, or whether they be the wanderings of imagination in a region beyond the limits of the understanding, I am at a loss to determine.' The concluding part of the sentence is expressive of the writer's modesty, or rather unwillingness to offend the admirers of Newton and Clarke; but no one, who will really be at the trouble to think, can be at a loss to determine respecting such vain attempts to go beyond the limits of the understanding by the aid of unmeaning phraseology.

Having spoken of the pre-established harmony of Leibnitz, Dr. Brown adds, 'To say of this hypothesis, which was the dream of a great mind—but of a mind, I confess, which was very fond of dreaming, and very apt to dream—that it is a mere hypothesis, is to speak of it too favorably.' And Mr. Stewart, with all his tenderness and partiality towards Leibnitz (for he is half inclined to make him, like Descartes, a sort of father of the experimental philosophy of the human mind), is constrained to say: 'To these visionary speculations of Leibnitz a strong and instructive contrast is exhibited in the philosophy of Locke; a philosophy, the main object of which is less to enlarge our knowledge than to make us sensible of our ignorance; or, as the author himself expresses it, to prevail with the busy mind of man to be cautious in meddling with things above its comprehension; to stop when it is at the utmost extent of its tether; and to sit down in quiet ignorance of those things, which, upon examination, are found to be beyond the reach of our capacities.' It would be well, indeed, if even Mr. Locke had kept this, as well as some other of his sound maxims, more constantly in view; for he, too, not unfrequently proses or philosophises with much profound inanity, or negative quantity of thought, by attempting to go beyond the length of his tether or the reach of his understanding.

'As a metaphysician,' says Mr. Playfair, somewhat satirically, 'the acuteness and depth of Leibnitz are universally admitted; but metaphysics are a science in which there are few discoveries to be made, and the man who searches in it for novelty is more likely to find what is imaginary than what is real.' The only semblance of merit belonging to Leibnitz as a metaphysician is the limitation made by him to the old maxim, descended from some of the Grecian philosophers, Nihil est in intellectu quod non fuerit in sensu. 'Nempe,' says Leibnitz, 'nihil est in intellectu quod non fuerit in sensu, nisi ipse intellectus.' There is nothing in the intellect which was not, or which has not been, in the sense or senses, except the intellect itself. The remark is excellent,' says Mr. Stewart, 'and does honor to the acuteness of the critic;' and, according to others, it threw a new light upon the whole science of metaphysics or philosophy of mind. The incorrectness of the remark, indeed, takes somewhat from its excellence; for how can the intellect be in the intellect? As expressed by Leibnitz the celebrated limitation of the scholastic maxim is a manifest bull. It is, indeed, calculated to call the attention to the intellect or mind itself, which was frequently lost sight of, or which had too little assigned to it, in distinction from the senses, by those who had the maxim about the senses being the origin of knowledge much in their mouth, as if there were nothing but the senses concerned in the business. In reference to Locke, however, the celebrated bull of Leibnitz, of the intellect itself being in the intellect, was not only a blunder in language, but founded in error of conception or a blunder of the understanding; as Mr. Stewart is indefatigable in showing to all the world. His words are, 'The misapprehensions so prevalent on the continent, with respect to Locke's doctrine on this most important of all metaphysical questions, began during his own life time; and were countenanced by the authority of no less a writer than Leibnitz, who always represents Locke as a partisan of the scholastic maxim, Nihil est in intellectu quod non fuerit in sensu; but it is not easy to conceive on what grounds it should have been urged as an objection to a writer who has insisted so explicitly and so frequently on reflection as the source of a class of ideas essentially different from those which are derived from sensation. To myself it appears, that the words of Leibnitz only convey, into a more concise and epigrammatic form, the substance of Locke's doctrine. Is any thing implied in them which Locke has not more fully and clearly stated in the following sentence? 'External objects furnish the mind with the ideas of sensible qualities; and the mind furnishes the understanding with ideas of its own operations.' The extraordinary zeal displayed by Locke, at the very outset of his work, against the hypothesis of innate ideas, goes far to account for the mistakes committed by his commentators, in interpreting his account of the origin of our knowledge. It ought, however, to be always kept in view, in reading his argument on the subject, that it is the Cartesian theory of innate ideas which he is here combatting; according to which theory, as understood by Locke, an innate idea signifies something coeval in its existence with the mind to which it belongs, and illuminating the understanding before the senses begin to operate. The very close affinity between this theory and some of the doctrines of the Platonic school prevented Leibnitz, it is probable, from judging of Locke's argument against it with his usual candor; and disposed him hastily to conclude that the opposition of Locke to Descartes proceeded from views essentially the same with those of Gassendi and of his other Epicurean antagonists. How very widely he was mistaken, in this conclusion, the numerous passages which I have quoted in Locke's own words sufficiently demonstrate.

'In what respects Locke's account of the origin of our ideas falls short of the truth will appear when the metaphysical discussions of later times come under our review. Enough has already been said to show how completely this account has been misapprehended, not only by his opponents but by the most devoted of his admirers; a misapprehension so very general, and at the same time so very obviously at variance with the whole spirit of his essay, as to prove to a demonstration that, in point of numbers, the intelligent readers of this celebrated work have hitherto borne but a small proportion to its purchasers and panegyrists. What an illustration of the folly of trusting, in matters of literary history, to the traditionary judgments, copied by one commentator or critic from another, when recourse may so easily be had to the original sources of information.'

Mr. Stewart is unwearied in vindicating Locke on this point: or rather in claiming the sanction of Locke's authority to what he deems the 'most important of all metaphysical questions.' It is such a good thing that the critic thinks there cannot be too much of it: he loves the theme so much as to be ever ringing changes upon it. Whether he and Mr. Locke, however, mean the same thing respecting the 'most important of all metaphysical questions' is very doubtful; and that Mr. Locke very frequently lost sight of any origin of ideas besides the senses, as completely as Gassendi or Epicurus, is to us very evident. How else is it to be accounted for that Mr. Locke's opponents or admirers should have equally, almost universally and uniformly, misunderstood him, according to Mr. Stewart's own account of the matter? Are they all to be charged with want of intelligence or with wilful and perverse misinterpretation? We requote a quotation of the critic's from Degerando, which, as he remarks, 'might furnish matter for some useful reflections, but I shall leave my readers to draw their own conclusions from it.' 'Another remarkable circumstance,' says Degerando, 'is, that the defence of the Kantians turned, in general, not upon the truth of the disputed proposition, but upon the right interpretation of their master's meaning; and that their reply to all objections has constantly begun and ended with these words, 'You have not understood us.' The constant reply of Mr. Stewart to the opponents, and to the disciples of Locke, concerning his doctrine respecting the origin of ideas, is 'You have not understood him.' It recurs, and recurs in endless succession, as if by some metaphysical law of continuity.

Having dwelt much longer on Leibnitz than we intended, we may as well dispose of German metaphysics at once by some notice of Kant: though it is not without some reluctance that we notice him at all, or give any place to a mere specimen of his absurdities, which possess not such redeeming qualities as those of Leibnitz; for they are as devoid of genius as they are of sense or reason. The following extracts are inserted from a publication of his humble disciple, and enthusiastic, and adoring, admirer, Thomas Wirgman, modestly entitled 'An Entirely New and Complete Science of Metaphysics, founded on Transcendental Philosophy.'

Metaphysics Reduced to a Complete Permanent Science, on the Principles of Transcendental Philosophy, as contained in Kant's Critic of Pure Reason.

'1. The mind consists of three original faculties which perform distinct functions, and are capable of being completely separated from one another; these are, sense, understanding, and reason. 2dly, Sense is susceptible of a complete definition, whereby it can never be confounded either with understanding or reason: it is the passive faculty of the mind, which receives impressions either from external objects or from the action of the mind upon itself, and is properly enough designated by Kant receptivity, which is again divisible into two parts arising from the original difference in the functions of these parts: the one Receptivity being constructed to receive parts following one another in strict succession, arising from the activity of the mind upon itself; which has received the name of time; the other being constructed to receive parts that exist all at once, or that lie one near another as in a plane, and is named space. 3dly, Understanding, which is wholly active, and therefore called spontaneity; and is divisible into twelve minor activities called categories, whose joint influence or action upon the matter furnished to them by the receptivities of sense produces an objective unity, i. e. in fact, an object, or, as it is commonly called, an object of sense. The action of this faculty is strictly limited to time and space. Whatever therefore is without the bounds of time and space, and yet occurs in the mind, must be accounted for from some other faculty; which leads us, 4thly and lastly, to reason, or the highest degree of mental spontaneity. The original constitution of this faculty is that it acts free from time and space. It is, in fact, a connecting activity, like that of the intellect or understanding, only of a purer nature, for it connects the categories themselves, which surely cannot now be confounded with the two receptivities of sense, time, and space; it must therefore be free from them, and out of their sphere. Hence the result of the action of this faculty is, a connexion of unities so pure, as not to be denominated objects of sense, but solely intellectual objects, and which never can become objects of experience; they may, therefore, very properly be termed ideas: such are the ideas of God, of the soul, of free will, of a future state, and of the moral laws, which experience, i. e. natural philosophy or physics, can never furnish; but, if they are to be met with at all, it will be in the science of metaphysics, that is, of reason itself.

'Transcendental philosophy has for its object the original use of understanding and reason in begetting knowledge. This science is completely à priori, and has nothing in it empirical. On this science alone rests the possibility of metaphysics.

'Metaphysics consider the categories, or original conceptions of understanding, as the last or highest conceptions to be found in the things, or as conceptions à priori of the things; and are divisible into metaphysics of nature and metaphysics of morals. The former comprehend the complex of all knowledge à priori, of that which does exist; and is theoretical. The latter con-

prehend the complex of all moral conceptions, or of all that which ought to exist; and is practical.

All philosophy that is à priori may be termed pure, in contradistinction to physics, or natural philosophy, which is à posteriori, and may be termed empirical.

The certainty and conviction that are found in the pure sciences of transcendental philosophy and metaphysics are obtained by the categorical mode of conclusion: in the mathematics by construction of the conceptions, which therefore admits of demonstration; while the certainty in the empirical science of natural philosophy can only be obtained by induction and analogy: modes of conclusion which can never beget strict universality.

But now let us see what our patient and modest philosopher says upon this subject in his own words. In the preface to his Prolegomena to all future Metaphysics, he speaks thus:—

'My intention is to convince all those who think it worth their while to occupy themselves with metaphysics, that it is indispensably necessary to suspend their labors for the present; to consider every thing hitherto done, as undone; and first of all to settle the question, whether such a thing as metaphysics be possible? If there really be such a science, how comes it that it cannot obtain, like other sciences, a universal and permanent reputation? If metaphysics be not a science, how does it happen that it continually pretends to this character, and yet constantly disappoints the human understanding with perpetual but unaccomplished hopes? Let us then demonstrate either our knowledge or our ignorance on this subject; something decisive ought to be determined with respect to the nature of this pretended science: for it must not be suffered to remain any longer in its present state. It seems quite ridiculous that, while every other science constantly advances, this science, which is universally appealed to as the oracle of wisdom itself, has always turned round upon the same spot, and never really advanced a single step. The patrons of metaphysics are indeed greatly decreased in number; and we do not find that those who feel themselves strong in other sciences choose to venture their reputation in this, where every one, no matter how ignorant in other things, boldly ventures upon a decisive judgment; conscious, as it should seem, that no criterion has yet been discovered to distinguish sound sense from shallow prating.

'However, it is not a thing so very unheard of, that after long cultivating a science, and while we are congratulating ourselves on our astonishing advancement in it, some one unexpectedly starts the question, whether such a science be really possible? For human reason is so fond of building, that it has frequently erected its castle, and then had to take it to pieces again, in order to examine the foundation. It is never too late to become rational; but it is hard to have this task to begin at an advanced period of life.

'To ask if a science be possible, implies that one doubts of its reality; and such a doubt is highly offensive to those whose whole treasure consists perhaps in this pretended knowledge. They will prepare, therefore, on all sides, to defend their ancient and legitimate possessions.

'I have, however, the confidence to predict that such readers of these prolegomena as think for themselves, will not only be convinced that no science of metaphysics exists at present, but that there never can be such a science, unless the requisites here stated, upon which its possibility rests, be first complied with. As, however, the enquiry respecting this science can never be entirely laid aside, because the interest of human reason is too intimately connected with it, they will see that a complete reform, or rather an entire regeneration, of metaphysics, on a plan hitherto untried, must unavoidably take place, however it may be for some time struggled against.

'Since the attempts of Locke and Leibnitz, or indeed since the origin of metaphysics, as far as its history reaches, no event has occurred so calculated to decide the fate of this science as the attack made upon it by Hume. He brought, it is true, no light into this department of knowledge; but he struck a spark, which, had it fallen upon combustible matter, and been carefully fanned, might have produced a flame. Hume took up a single but important conception of metaphysics; namely, that of the connexion of cause and effect (consequently the derived conceptions of power, action, &c.); and challenged reason, which holds it up as its own produce, to say by what right it concludes, that one thing may be so constituted, that if it be given, something else must necessarily be inferred; for this is the meaning of the conception of a cause. He proved, beyond contradiction, that it is quite impossible for reason to discover in the conceptions themselves any such necessary connexion, since we cannot see why, because something is, something else must also necessarily be; and consequently we are at a loss to know how the conception of such a connexion à priori can have arisen. Hence he concluded that reason entirely deluded itself with this conception, falsely considering it as its own offspring, while in fact it is nothing more than a bastard of the imagination, which, being made pregnant by experience, has brought certain representations under the law of association, and substituted a sort of subjective necessity, namely, habit, for an objective one, founded upon real knowledge. He concluded, therefore, that reason had no faculty to think such connexions even generally, because its conceptions would in that case be mere fictions, and all its pretended knowlege à priori nothing but a false value given to common experience. In other words, that no such science as metaphysics is at all possible.

'Notwithstanding this rash conclusion, however, Hume calls his very destructive philosophy by the name of metaphysics, and sets a great value upon it. 'Metaphysics and morals,' says he, 'are the most important branches of science; mathematics and natural philosophy are not of half the value.' This acute man, however, looked merely to the negative advantage, which would arise from lowering the pretensionsof speculative

reason, and quieting the disputes of men. But here he lost sight of the positive harm which would occur, were reason deprived of its most important prospects, which alone hold out to the will the highest object of all its exertions.

'Yet, however hasty and incorrect his inference was, it was grounded at least upon investigation; and this investigation certainly deserved that the philosophers of his day should have united their endeavours to solve, if possible, his problem in the sense in which he delivered it; and, had they succeeded in this, an entire reform of the science would have immediately followed. It was, however, the fate of metaphysics, ever unfortunate, that no one should understand Hume's intention. It is painful, indeed, to observe how entirely his opponents, Reid, Oswald, Beattie, and Priestley, missed the point of his question, always admitting, as a matter of course, the very thing which he doubted, and proving with vehemence, and mostly with great indiscretion, that which it never entered his mind to doubt. They thus overlooked his hint at improvement, and suffered every thing to remain in its original state, as if nothing had happened. The question was not, whether the conception of cause be correct, useful, and indispensable, to all knowledge of nature; for this Hume never doubted? but whether this conception be thought by reason à priori, and whether it possess, on that account, an internal truth, independently of all experience, and therefore a more extensive utility, not limited merely to objects of experience. It was of this great problem that Hume sought the solution. His enquiry regarded merely the origin of the conception of cause, and not its indispensability in the application. Had its origin but once rightly been made out, the conditions of its use, and the extent of its validity, would have become evident of themselves.

'But, in order to solve this problem, the opponents of this celebrated man would have been obliged to enter very deeply into the nature of reason, as it is occupied with pure thinking, which was not quite convenient to them. They therefore invented a more ready means of attack and defiance, which required no such deep insight; they appealed to common sense. Certainly it is a great gift of heaven to possess common sense, or, as it is sometimes termed, a plain understanding. But we must prove that we possess it by facts, by the considerate and rational things which we think and say, not by the mere appeal to it as an oracle, while we can produce nothing in its justification. When our philosophy and science begin to fail, to appeal then, and not till then, to common sense, is one of the subtle inventions of modern times, by which the shallowest prater may boldly cope with and maintain himself against the deepest thinker. But, while the smallest spark of true philosophy remains, I have no doubt that we shall be cautious of taking refuge in this expedient. The appeal to common sense is, after all, but an appeal to the opinion of the multitude; which the philosopher must blush to make, but on which the popular witling gladly sounds his momentary triumph.

'I should conceive, however, that Hume might lay claim to a sound understanding just as well as Beattie; and, besides this, to something that the latter certainly did not possess; namely a critical reason, which knew how to keep common understanding within its proper bounds, and to prevent its losing itself in speculations; for common sense does not understand the principles on which it acts, and therefore cannot know when it is sound and when not. A common hatchet may serve very well to shape timber, but a more delicate instrument is required for fine engraving. Thus the common understanding, and the speculative, are both useful in their way; the one in judgments immediately applicable to experience, the other in general judgments, as in metaphysics, where common sense cannot judge at all.

'I candidly own that this hint of David Hume was the circumstance that first disturbed my dogmatical slumbers, and gave a new direction to my researches, in the field of speculative philosophy. I was far from listening to his inferences, which proceeded merely from his own representing to himself his problem in its whole extent, but investigating merely a part of it, the solution of which was impossible without a comprehensive view of the whole. When we proceed upon a well-grounded, though not thoroughdigested, thought, we may reasonably hope, by perseverance, to carry it further than the acute genius to whom we are indebted for the first spark of this light.

'I first examined whether Hume's objection might not be rendered a general one; and soon found that the idea of cause and effect is by no means the only one in which the understanding represents to itself a connexion of things à priori, but that the whole of metaphysics consists of nothing else. I endeavoured to ascertain their number; and, having done this to my satisfaction upon a single principle, I proceeded to the deduction of these conceptions. I now saw, very clearly, that they were not derived, as Hume had supposed, from experience, but originated in the understanding itself. This deduction, which appeared impossible to my acute predecessor, and which had never even entered the mind of any one else (for although every body used these conceptions, no one thought of enquiring upon what their objective validity is founded);—this deduction, however, was the most difficult task that could be undertaken for the establishment of metaphysics; and to this, unfortunately, no existing metaphysics could afford the smallest aid; for it is this very deduction which must first constitute the possibility of metaphysics itself.

'Having thus succeeded in the solution of Hume's problem, not merely in a partial view, but with reference to the whole faculty of pure reason; I could now proceed, by safe, though indeed slow, steps, to determine completely, and upon general principles, the entire compass of pure reason; to ascertain its limits, and the sphere of its exertion. This, indeed, was all that was required for erecting a system of metaphysics upon a proper and solid foundation. But I am aware, that the solution of Hume's problem in its entire extent (in other words, the 'critic' of

pure reason itself) may have the same fate as the problem. It will be judged of incorrectly, because it is not understood; it will be misunderstood, because men are more disposed to turn rapidly over the leaves of such a book than to study it thoroughly. It will be thought dry and obscure, and be found to contradict all the received conceptions: and, besides this, it will be considered prolix.

'I freely confess that I did not expect to hear philosophers complain of the want of popularity and entertainment, in a work that treated of the existence of a valuable branch of knowledge, of a science indispensable to mankind, and which can only be attained by an adherence to the strictest rules of scholastic precision. It may indeed hereafter become popular; but it must not make its first appearance in a popular shape. That obscurity, however, which may have arisen from the extensiveness of the plan, rendering it difficult to seize and comprehend the chief moments upon which it rests, it is the object of the present prolegomena to remove.

'The work which contains the science of the faculty of pure reason, in its whole extent and boundary, must always be considered as the object to which these prolegomena refer, merely as previous exercises. The 'critic of pure reason' must stand firm as a system complete in all its parts before we can think of advancing one step in metaphysics, or even entertaining the most distant hope of such a science.

'We have been so long accustomed to see old and hackneyed observations brought out with a new title, and dressed in a systematic costume, according to the fancy of authors, that nothing further will be expected by the greater part of readers in the 'critic of pure reason.' These prolegomena, however, will show, that it contains an entirely new science, of which no one had previously conceived the thought, and to which nothing hitherto known could at all contribute, except the hint afforded by the doubts of Hume, who himself, however, did not foresee the possibility of such a formal science, but in his distress, in order to save his vessel, ran her upon the shore of scepticism, there to lie and rot; instead of which it has been my business to provide her a pilot, furnished with a complete chart and compass, who shall be able to navigate her safely round the world.

'To enter upon a new science which is entirely separated from all others, and indeed the only one of its kind, with this prejudice, that we are already able to decide upon it by means of knowledge elsewhere acquired (though, in fact, the truth of this pretended knowledge is the very thing in question), can tend to nothing else than to make us imagine all we find in it has been previously known to us, because, perhaps, some of the expressions have been used before. The whole will, however, appear extremely disfigured, nonsensical, and in fact mere gibberish, because we do not take the thoughts of the author as his foundation, but substitute our own in their stead, which in us have become a second nature through long habit. However, the very extensiveness of the work, even where it depends upon the nature of the science itself, and not upon mere style; its unavoidable dryness and scholastic precision; are properties which, while they contribute to the perfection of the science, will undoubtedly be injurious to the reception of the work itself.

'Every one is not endowed with the gift of writing so subtilely, and at the same time in so captivating a manner, as Hume; or so soundly, and yet so elegantly, as Moses Mendelsohn; I flatter myself, however, I could have given popularity to my style, had it been my design merely to form a plan and recommend its execution to others, and had I felt less at heart the good of the science which has so long occupied me. It does indeed require great perseverance, and no little self-denial, to give up the gratification of an immediate favorable reception for the prospect of a late, though lasting, approbation.

'To form plans is frequently a mere luxurious and ostentatious employment of the mind, which, with the air of an inventive genius, requires what it is unable to perform, censures what it cannot amend, and sets others upon the search for what it does not itself know where to find. Nevertheless, to form a good plan merely of a general critic of reason requires something more than may be imagined, unless indeed it is to consist, as is usually the case, of mere declamation and good wishes. Pure reason is so insulated, and so thoroughly connected within itself, that we cannot touch upon a single point without affecting every other, and can establish no one part permanently without assigning to every other its proper place and influence upon the whole; for, as there is nothing exterior to this science that can assist in rectifying our judgment concerning its contents, the validity and the use of every part must depend entirely upon the relation in which it stands to the rest; just as, in examining the structure of an organised body, the use of each organ can only be inferred from a complete conception of the whole. Hence we may say, of a critic of pure reason, that it cannot be relied upon unless it be completely elaborated to its minutest elements; and therefore, that, if the whole is not accomplished, we have done nothing at all.

'Notwithstanding, however, that such a plan, were it possible that it could have appeared prior to the critic itself, would have been unintelligible and useless, yet, coming after the critic, it is of the greatest advantage, since it will enable us to overlook the whole, and to examine separately the principal points upon which it depends.

'The plan which I here offer succeeds to the work itself, and may therefore proceed now according to an analytical method, though the original work was formed synthetically, as indeed it was necessary that it should, in order that the science might exhibit all the articulations in the organisation of this peculiar faculty of knowledge. Those who find even this plan obscure, which I here place as an introduction to all future metaphysics, should consider, that it is not exactly necessary for every one to study metaphysics; that many men possess talents, well calculated to succeed in useful and even difficult sciences, which come nearer to intuition; but fail in enquiries that relate to mere abstract con-

ceptions; and that it is better for them to apply their intellectual exertions to other objects. But he who shall hereafter undertake to decide upon, or to construct, a new system of metaphysics, must absolutely satisfy those demands which are here made upon it. He must either adopt my solution, or refute it altogether, and substitute another in its place; from this he cannot be excused.'

We feel that these extracts are abundant; but must not omit the following method of *simplifying* the science adopted by this school:—

ELEMENTS OF METAPHYSICS.

INTUITION,	CONCEPTION,	IDEA,
present in Time and Space.	absent in Time and Space.	out of Time and Space.

THE

MIND.

SENSE.

Two receptivities.

Time. Space.

UNDERSTANDING.

Twelve Categories.

Quantity.	*Quality.*	*Relation.*	*Modality.*
Unity,	Reality,	Substance and Accident,	Possibility,
Multitude,	Negation,	Cause and Effect,	Existence,
Totality	Limitation.	Action and Re-action.	Necessity.

REASON.

Six ideas.

Absolute Totality.	Absolute Limitation.	Absolute Substance,	Absolute Necessity.
		Absolute Cause,	
		Absolute Concurrence.	

Axioms of Metaphysics.

1. Consciousness is the power to distinguish ourselves from surrounding objects and from our own thoughts.
2. Time is the form of internal sense.
3. Space is the form of external sense.
4. Sense makes Intuitions.
5. Understanding makes Conceptions.
6. Reason makes Ideas.

Definitions.

1. Intuitions joined to conceptions make knowledge.

2. Conceptions joined to conceptions make thoughts.

Remark.—The above axioms originate in transcendental philosophy, on which the possibility of metaphysics as a science rests.

As the preceding table exhibits the entire elements of metaphysics, it is only requisite, for the establishment of the science, to give a complete explanation of each part, and to prove that these elements are neither deficient nor redundant.

The Mind

1. The mind, in the most extensive meaning of the word, implies a faculty of representing something to itself: and therefore may be termed a representing faculty,

Proof.—In every thought, conception, knowledge, judgment, idea, &c., the mind always represents some object to itself; or the thought, conception, &c., is perfectly empty, and completely senseless.

2. Every representation requires a representing subject and a represented object.

Proof.—The representing subject, by acting upon the object that has occurred in the mind, produces the representation. The subject and object taken together are the cause, and the representation is the effect. And no representation whatever is possible without these three parts: that is to say, subject and object as cause; and representation as effect.

3. In every representation, thought, conception, knowledge, &c., there must be an object consisting of parts; and these must be united into a whole.

Proof.—For that which hath no parts is absolutely nothing, and therefore cannot be representable as an object; and, unless these parts are connected into a whole, or unity, no representation of any one thing would be possible.

Sense.

1. Sense is the passive faculty of the mind, that receives the parts of which the object in the representation consists, and connects them into a whole, or unity, which is called intuition.

Proof.—For, if sense do not receive the parts of which the object or matter of every representation consists, then we create the objects, which is absurd. And until these parts are connected into a whole, or unity, no object could occur in a representation.

Explanation of terms employed in the science of metaphysics.

Sense in its passive capacity is called receptivity; for it receives the variety or matter of all representations which the mind could not create.

Sense in its active function is called spontaneity of the first degree, as merely uniting the parts which are received by the mind into that species of unity which is called intuition.

Remark.—An intuition is not an intelligible object, for the intellect has not yet operated upon it; still we are conscious of the presence of an object, though we do not know what it is.

2. As sense receives, it is clear that it must receive a variety of parts, otherwise it has nothing at all to receive. Now there are only two general varieties, the one whose parts co-exist, the other whose parts are in strict succession.

Proof.—All objects in space have their parts co-existing; all objects which are in time only, have their parts following one another. The former comprehend all external sensible objects; the latter the effects and relations of these external objects, or the internal sensible state of the subject. But these two descriptions include every possible object.

3. As the receptivity of sense receives objects, the parts of which are either co-existent or successive, it may be divided into two parts.

Remark.—This division is not only very natural, but it is also indispensable; for, without it, we should be unable to give accurate definitions of time and space.

4. The receptivity which receives an object whose parts co-exist is external receptivity, or space.

Proof.—For, when we analyse our notion of space, we find it to consist of a variety of co-existing parts, connected together into a unity. But space alone is that whereby an object consisting of a variety of co-existent parts can occur; which is precisely the case with the external receptivity; therefore space is external receptivity.

5. The receptivity which receives an object whose parts are successive, that is, merely the effect of some external object; and which, therefore, exist in time only, and can only be an internal object; is internal receptivity, or time.

Proof.—For, when we analyse our notion of time, we find it to consist of a variety of parts in strict succession, connected together into a unity; and time is that alone wherein an object consisting of a variety of parts in succession can occur; which is precisely the case with internal receptivity; therefore time is internal receptivity.

Explanation of terms.

Sensation is an alteration which takes place when the receptivity is affected, and is the ground of intuition.

Intuition is a sensible representation which arises immediately upon the receptivity being affected, and is either external intuition, when its object is in space, that is, an external phenomenon; or internal intuition, when its object is in time only; that is, an internal phenomenon, or the effect of an external one.

Phenomenon means appearance, and is used to distinguish the object in the representation from the object out of it, which is its cause, and is called noumenon.

Noumenon is the thing in itself, that is, independent of our faculties; for it is then out of time and space; that is, out of the sphere of knowledge. Of noumena, therefore, we can know nothing.

Conclusion.—Thus we have seen that the mind is both active and passive. Its receptivity receives the matter of knowledge, which it could not create. Its spontaneity connects this matter into a unity or form, and thus produces an intuition. Hence, sense or the first degree of spontaneity, constitutes the power of forming intuitions.

Understanding.

1. Understanding is an active faculty, a spontaneity of the second degree. It comprehends an intuition under a conception, or under the objective unity; that is, renders it an intelligible object.

Proof.—For, until an object is classed by the understanding, it is a mere intuition, or an unintelligible object; but, the instant the intellect has operated upon it, it becomes intelligible; I may then say I understand it, and know what it is.

2. To render an object intelligible is to give to it a precise quantity, a particular quantity, a determinate relation, and a distinct degree of certainty, called modality.

Proof.—For that thing which has no precise quantity, e. g. that is neither a mathematical point nor an entire world, nor any part of a world; and which has no particular qualities, e. g. is neither hard, soft, &c., and which stands perfectly alone, without any relation to other things, neither being a body, nor an effect of a body, nor a part of a whole; is completely unintelligible.

3. The understanding consists of twelve primary and original connecting acts called categories, and classed under the four heads of quantity, quality, relation, and modality.

Remark.—The whole fabric of metaphysics either stands or falls upon the proof of this position, which will be given in the sequel, under each head as it arises; and, should it fail, then indeed will metaphysics be thrown into the utmost confusion, and be again the stumbling-block of the learned; but should it succeed, as it is presumed it will, we may then boast, that at length metaphysics has become a science which surpasses geometry, since it explains what the geometrician always assumes or takes for granted,

namely, his axioms, together with time and space.

4. Quantity consists of unity, multitude, and totality; and must belong to every thing.

Proof.—For that which is without quantity, that is to say, which is neither one, many, nor all, is no intelligible object; consequently not representable: i. e. it is nothing.

5. Quality consists of reality, negation, and limitation; which means that a thing either is, or is not; and, if it is, that it is limited

Proof.—To say that a thing is, and yet is not a real thing, is to contradict ourselves. And to say that there can be any real thing, and yet without limits, is certainly going beyond the bounds of intelligibility, which confines to limits; for we know nothing of the infinite.

6. Relation includes only that of a substance to its properties, of a cause to its effect, or of action to re-action.

Proof.—For, when we examine really existing things, we find they stand in relation to other existing things; and without such relation they are by no means conceivable; e. g. we cannot conceive a substance without its properties, a cause without its effect, or a whole without its parts.

7. To constitute an intelligible object means to comprehend the intuition produced by sense under the objective unity; i. e. to judge.

Proof.—For, until an intuition is comprehended under the objective unity, it is perfectly unintelligible. That is to say, that the understanding, by classing an intuition under quantity, quality, and relation, constitutes the intelligibility of the given matter or object in the intuition; so that it perfectly harmonises with the fact to say, that sense receives the matter of all knowledge, and understanding produces its form.

8. An intuition united to a conception produces knowledge.

Proof.—It is evident that knowledge cannot consist of mere conceptions united together; for I cannot say, because I conceive a certain thing, that I therefore know it; but, the instant I class a particular intuition under a certain conception, I can say I know it; e. g. This building is a castle.

9. Modality consists of possibility, existence, and necessity. This expresses the mode or manner in which the intuition belongs to time; namely, it may be in any time, or it is in a certain time, or it must be in all time.

Proof.—Nothing can be more evident than that an intuition may be possible; that is, such that it may exist in any time; or it may be actual, that is, really exist in a certain time; or it may be necessary, that is must exist in all time; as the very contrary is impossible, e. g. a circle without a centre.

10. The twelve categories of the understanding, as arranged under the four heads of quantity, quality, relation, and modality, are not only essentially necessary to the intelligibility of objects of sense, but they are actually complete in their number, that is, neither deficient nor redundant.

Proof.—It is quite impossible to add one more category to the understanding; and, if we take one away, the whole faculty will be destroyed. For, if we speak of a number, it must either be one, many, or all; and no other case is possible. Secondly, if we have any thing in our thoughts, it must be a reality, or the absence of a reality; but, if a reality, it cannot be infinite, therefore it must be limited by negation; that is, there may either be a reality or no reality; but, if there be a reality, it must be limited; and no other case is possible. Thirdly, We can only be affected by things and their properties, by causes and their effects, or by parts and their wholes. Nothing more than this is conceivable, therefore much less knowable; for experience consists entirely of these relations. Lastly, With respect to modality; things may either be in any time, that is merely possible; or in a certain time, that is actual; or they may be in all time, and to be destroyed only with the destruction of time, that is, they may be necessary. Of this nature are the categories themselves, for without them there could not possibly be any experience whatever.

Explanation of Terms.

Quantity is that which is produced by adding one to one; and expresses the conception of a number in general.

Quality is the quantity of being in time; for every sensible reality has a being in time, that is, a beginning, middle, and end. But this series of sensations can only be measured by a degree; therefore quality is expressed in our conception of a degree in general.

Substance is that which lasts in time, and has properties that change; or it is the permanent in space, in which the properties or accidents inhere.

Cause is a power in one substance to act upon another, and thus to produce a third thing called effect. The first substance, or intuition is called the subject or agent; the second or substance intuition is called the object, or patient, being the thing acted upon; and thence arise necessarily and immediately the effect. Hence cause may be defined to be the action of the subject upon the object, whereby the effect is produced. Cause precedes in time, and effect succeeds; but not vice versâ.

Concurrence means the mutual action and reaction of co-existing substances or intuitions, whereby one determines the other's place in space, and vice versâ, as parts of a whole.

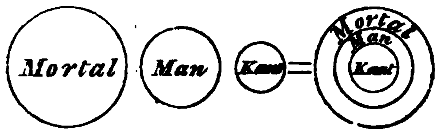
Conclusion.—Thus we have shown that the understanding is purely an active faculty which gives unity or form to the matter received by sense; that is, renders an intuition an intelligible object. This faculty is therefore a spontaneity of the second degree, but strictly limited to time and space; or it is the power of forming conceptions.

REASON.

1. Reason is an active faculty, or spontaneity of the third or highest degree. It comprehends a conception together with its intuition, under an idea, and thus renders a conclusion possible.

Proof.—For what is a conclusion, but the comprehending the individual under the particular, and this under the universal? as illustrated by the following figure:—

Idea Conception Intuition



Totality Multitude Unity

Hence the conclusion; therefore Kant is mortal. But how could a conclusion take place without a faculty capable of producing an absolute totality, or a totality free from time and space, and which admits of no exceptions whatever? If the highest conception of idea in a ratiocination were particular, instead of universal, no conclusion would be possible. But of the fact of conclusion no one doubts; therefore the faculty to produce it must be admitted.

2. To render an object comprehensible is to class it under an idea of reason, or under a conclusion.

Proof.—If the intuition Kant were only classed under a conception of understanding, it would then be an intelligible object, but limited in all respects as to its duration and every other property; for, as an object of experience, it would only be necessary on account of its cause; and we could not predicate of it any thing absolutely; but, reason being a faculty that acts free from time and space, and their conditions, it enlarges our views by allowing what the understanding has done, and yet hinting that this does not include all the properties of which objects of nature are possessed, that they may have a nature of their own, independent of that connected with our mode of representing them; but this it can only do by classing the object under an idea: hence the judgment, all men are mortal.

3. Reason is only capable of exerting three modes of concluding; namely the categorical, the hypothetical, and the disjunctive.

Proof.—For this faculty can only arrange ideas of things and their properties by its categorical concluding act; causes and effects by its hypothetical; and parts and wholes by its disjunctive concluding act. But besides things and properties, causes and effects, and parts and wholes, there are no other things in the whole universe the ideas of which reason could arrange one under another. Therefore there are no other concluding acts but the categorical, hypothetical, and disjunctive.

4. Reason arranges the categories of quantity one under another, thus: unity under multitude, and these under totality; and thereby produces the idea of absolute totality.

Proof.—Every thing connected by the understanding is strictly limited. But we really have the idea of something which goes far beyond the limited things of nature; and the only way in which this idea is obtained is by a conclusion of reason; for it is evident that the categories unity, multitude, and totality, are themselves unconditioned things, and that, being connected into a unity by reason, this unity must also be absolute or unconditioned. Thus reason will have absolute completeness; and, when this mode of action is applied to the other categories, the following ideas result.

5. Reason connects the categories of quality—which are reality, negation, and limitation, into the idea of absolute limitation.

Proof.—For every reality in time and space is limited by negations. It is a variety whose parts can be measured by degrees only, and these by other degrees still smaller; and this without end. But reason will have absolute completeness, and thus forms the idea of absolute limitation.

6. Reason connects the categories of relation, which are each of them already compound notions, into the following ideas.

First, substance and accident into the idea of absolute substance.

Proof.—For all the substances in the world are nothing more than a collection of properties existing in time and space; and every analysis of these substances only produces another set of properties without end; but reason, which acts free from time and space, and will have absolute completeness from the category of substance and accident, raises the idea of an absolute substance, which can never again become a predicate of any other substance.

Secondly, Cause and effect into the idea of an absolute cause.

Proof.—For all he causes in time and space are nothing more than effects from preceding causes, and these causes are again effects of other causes ad infinitum. But reason, which will have absolute completeness in a series of causes and effects, raises to itself an idea of an absolute cause which cannot be the effect of any other cause.

Thirdly, Action and re-action into the idea of absolute concurrence.

Proof.—For all the substances in the world are endowed with causes which work upon other substances, and thus mutually determine each other's place in space. All these substances are themselves only effects of other substances, and so on ad infinitum. But reason, which acts free from time and space, will have an absolutely complete series of causes and effects, and thus raises the idea of absolute concurrence.

Remark.—The most important notions that concern us, as accountable beings, depend entirely upon this peculiar faculty of reason in raising these ideas. For how otherwise could we obtain the idea of our own soul, a first cause, or the deity? and without these notions we should not differ from the brute creation, and must for ever give up our claim to the rank of rational beings. It may further be remarked that the sciences of psychology, cosmology, and theology, have their roots in these important ideas of reason. For the idea of absolute substance leads to psychology, the idea of a first cause leads to cosmology, and the idea of an absolute mutual concurrence leads to the science of theology.

7. Reason connects the categories of modality, which are possibility, existence, and necessity, into the idea of absolute necessity.

Proof.—For in time every change is determined by a preceding change, and consequently there is no absolute necessity. But reason, which acts free from time, forms an idea of something which

does not depend on a preceding change, and which is exempt from the conditions of time; hat is, an idea of absolute necessity.

Conclusion.—Thus we have shown that reason, or the highest degree of spontaneity, is an active faculty of so pure a nature as to be able to connect parts which are already out of time and space into wholes called ideas. For what are the categories of understanding, but parts of this description? On these ideas is founded the erroneous notion, that we can know immaterial existences; whereas we can only have ideas of them. Hence reason, or the third degree of spontaneity, is the power of forming ideas.'

Mr. Horne Tooke, having made some quotations from Mr. Harris and lord Monboddo, exclaims, with too much levity perhaps, 'If this be philosophy, give me back my Tom Thumb again.' But what shall we say to the 'critic' of pure reason? If this be transcendental philosophy, give us back the philosophy of Aristotle again; for, taking chimera for chimera, as Gassendi said of the vortices of Descartes and the atoms of Epicurus, we cannot help having some partiality for the one that is 2000 years older than the other. According to Dr. Willich 'The whole critique of pure reason is established upon this principle, that there is a free reason independent of all experience and sensation.' If we may believe madame de Staël this notable critique of pure reason is to be regarded 'as having given the impulse to all that has since been done in Germany both in literature and philosophy; but, according to the respectable testimony of Degerando, a pure Kantian is not to be found at present in Germany. 'In short,' he remarks, 'the Critique of Pure Reason, announced with pomp, received with enthusiasm, disputed about with fury, after having effected the overthrow of the doctrines of Leibnitz and Wolff, could no longer maintain itself, and has produced no permanent result but divisions and enmities, and a general disgust towards all systematic creeds.' But enough and more than enough.

'Indignandum de isto, non disputandum est. * * * Quid te torques et maceras, in ea quæstione quam subtilius est contempsisse quam solvere?' How applicable is the import of these quotations to many more than Kant, who is indeed a most worthy successor of Leibnitz, and a fit specimen of German philosophers.

LOCKE.

Having attempted to clear away some metaphysical rubbish, we now return to the celebrated author of the Essay concerning Human Understanding; a work which we think with Mr. Stewart has been much more applauded than read. Indeed much of the applause, we suspect, is owing to the very circumstance that it has been little read; and, if there be any truth in Voltaire's criticism on Dante, the praise of Locke is likely to continue and increase 'aye more and more;' for it may now almost be said that nobody reads him. This we feel confident of, that many of his most zealous eulogists, who have the phrases the great Locke, the immortal Locke, ever and anon in their mouth, never carefully read his great work. We have read it, and re-read it, and attempted inwardly to digest it; but we have all ways found it a laborious task, and we fear that either our digestive system is indifferent, or that much of the Essay concerning Human Understanding is not very convertible into intellectual aliment. That there are some things in it 'hard to be understood' is evident from the very circumstance so much and so often insisted on by Mr. Stewart, as already noticed. This unintelligibleness we think attributable to the following causes:—

1. Mr. Locke, notwithstanding all his sage remarks on the folly of meddling with things above the comprehension of the understanding, is ever and anon attempting to sound depths too profound for the length of his line; or rather he plunges headlong into the abyss and chaos of scholastic subtleties. This is particularly the case in much of Book II., in not a little also of Book IV., as well as in other parts of the essay. It may seem strange indeed that Mr. Locke should have fallen into this error; but it only proves that philosophers, like other men, often transgress against their own maxims, not only in the conduct of life (as in the case of the philosopher so strikingly depicted by Johnson in his Rasselas) but in the conduct of their understanding—even in their speculations. What can be more judicious than the following remarks of Mr. Locke? 'If, by this enquiry into the nature of the understanding, I can discover the powers thereof; how far they reach, to what things they are in any degree proportionate, and where they fail us; I suppose it may be of use to prevail with the busy mind of man to be more cautious in meddling with things exceeding its comprehension; to stop when it is at the utmost extent of its tether; and to sit down in a quiet ignorance of those things which, upon examination, are found to be beyond the reach of our capacities. We should not then perhaps be so forward, out of affectation of a universal knowledge, to raise questions and perplex ourselves and others with disputes about things to which our understandings are not suited, and of which we cannot frame in our minds any clear or distinct perception, or whereof (as it has perhaps too often happened) we have not any notions at all. If we can find out, how far the understanding can extend its view; how far it has faculties to attain certainty; and in what cases it can only judge and guess, we may learn to content ourselves with what is attainable by us in this state.' * * * 'This was that which gave the first rise to this Essay concerning the Understanding. For I thought that the first step towards satisfying several enquiries the mind of man is apt to run into was, to take a survey of our own understanding, examine our own powers, and see to what things they were adapted. Till that was done, I suspected we began at the wrong end, and in vain sought for satisfaction in a quiet and sure possession of truths that most concerned us whilst we let loose our thoughts into the vast ocean of being; as if all that boundless extent were the natural and undoubted possession of our understandings, wherein there was nothing exempt from its decisions, or that escaped its

comprehension. Thus men, extending their enquiries beyond their capacities, and letting their thoughts wander into those depths where they can find no sure footing, it is no wonder that they raise questions, and multiply disputes, which, never coming to any clear resolution, are proper only to continue and increase their doubts, and to confirm them at last in perfect scepticism. Whereas, were the capacities of our understanding well considered, the extent of our knowledge once discovered, and the horizon found, which sets the bounds between the enlightened and dark parts of things, between what is and what is not comprehensible by us; men would perhaps, with less scruple, acquiesce in the avowed ignorance of the one, and employ their thoughts and discourse with more advantage and satisfaction in the other.' Book I. c. i.

All this had been better expressed before, that is, with less verbosity and more precision; but the manner in which it is dwelt upon as well as many repetitions of the same thought, in different parts of the work, shows that it was not a casual, but a fixed sentiment of the author; yet how frequently does he lose sight of it! Indeed we can hardly persuade ourselves sometimes that he was aware of what he had stated in the above paragraph, or that he could have deliberately annexed what seems to be the obvious meaning to his words.

2. Another and a chief cause of the confusion which pervades the Essay concerning Human Understanding was the author's unskilfulnes in words, or the want of mastery in language considered as the instrument and medium of thought. He is a remarkable contrast to Hobbes and even to Bacon in this respect. Indeed their admonitions and example, as to the importance of attending to the nature of language and the meaning of words, in reference to the correct reception and communication of knowledge, seem to have been wholly lost upon him. He says, Book III. c. ix, 'I must confess, then, that when I first began this discourse of the understanding, and a good while after, I had not the least thought that any consideration of words was at all necessary to it. But when, having passed over the original and composition of our ideas, I began to examine the extent and certainty of our knowledge, I found it had so near a connexion with words that, unless their force and manner of signification were first well observed, there could be very little said clearly and pertinently concerning knowledge, which, being conversant about truth, had constantly to do with propositions. And, though it terminated in things, yet it was for the most part so much by the intervention of words that they seemed scarcely separable from our general knowledge. At least they interpose themselves so much, between our understanding and the truth which it would contemplate and apprehend, that like the medium through which visible objects pass, their obscurity and disorder does not seldom cast a mist before our eyes, and impose on our understandings. If we consider, in the fallacies men put upon themselves as well as others, and the mistakes in men's disputes and notions, how great a part is owing to words, and their uncertain or mistaken significations, we shall have reason to think this no small obstacle in the way to knowledge; which, I conclude, we are the more carefully to be warned of, because it has been so far from being taken notice of, as an inconvenience, that the arts of improving it have been made the business of men's study, and obtained the reputation of learning and subtilty, as we shall see in the following chapter. But I am apt to imagine that, were the imperfections of language, as the instrument of knowledge, more thoroughly weighed, a great many of the controversies, that make such a noise in the world, would of themselves cease; and the way to knowledge, and perhaps peace too, lie a great deal opener than it does.'

This is the burden (for the author always seems toiling at his task—there is never that appearance of ease and mastery inseparable from original genius, as in Bacon and Hobbes, and other powerful writers) of the third book, by far the best of the whole work, as justly observed by Mr. Stewart; who remarks, with equal justice, that it was an after-thought. If, indeed, it had been a forethought, many other parts of the essay would never have been written, and all the parts of it would have been written in a very different manner. It is much better written than any of the other books; but even from this (the composition is so indifferent) it is scarcely possible to extract a perfect sentence—we mean not rhetorically but logically considered: as to extracting a good paragraph it is out of the question.

'In one of Locke's most noted remarks concerning the varieties of genius, or rather the difference between wit and judgment,' says Mr. Stewart, 'he has been anticipated by Malebranche, on whose clear yet concise statement he does not seem to have thrown much new light by his very diffuse and wordy commentary.' This remark concerning diffuseness and wordiness, as we observed of that about fanciful hypotheses by Warburton, is not the less true and forcible for coming from Mr. Stewart. Diffuseness and wordiness, or say wordiness and indistinctness, which are almost identical, are the besetting sin of all Locke's compositions. He is constantly laboring at it and about it, but seldom succeeds in expressing the truth, the whole truth, and nothing but the truth. The third book of the essay, by far the best of the whole in every view, as already remarked, is little more than a 'very diffuse and wordy commentary' on a few sentences of Bacon and a few paragraphs of Hobbes; the last of whom in particular expresses with such clearness and force the principle so much dilated and encumbered by Locke, and lays so much reiterated emphasis upon it, as to render it almost unaccountable that the author of the Essay concerning the Human Understanding should have been so long before he was aware of its importance, and that he should have turned it to so little account.

The noted remark referred to by Mr. Stewart, as a very diffuse and wordy commentary on a clear and concise statement of Malebranche, is in reality a deterioration of a statement given by Hobbes; though expressed by the commentator with a clearness, and brevity, and precision, which he very seldom equals. We will give the

quotations in order from Locke, Malebranche, and Bacon, subjoining the statement of Hobbes which Mr. Stewart either did not know of or would not bring into the comparison before his readers.

'If in having our ideas in the memory ready at hand,' says Mr. Locke (Book II. c. xi.) 'consists quickness of parts; in this of having them unconfused, and being able nicely to distinguish one from another, when there is but the least difference, consists, in a great measure, the exactness of judgment and clearness of reason which is to be observed in one man above another. And hence, perhaps, may be given some reason of that common observation, that men who have a great deal of wit, and prompt memories, have not always the clearest judgment or deepest reason. For wit, lies most in the assemblage of ideas, and putting those together with quickness and variety wherein can be found any resemblance or congruity, to make up pleasant pictures and agreeable visions in the fancy; judgment on the contrary lies quite on the other side, in separating carefully, one from another, ideas wherein can be found the least difference, thereby to avoid being misled by similitude, and by affinity to take one thing for another.'

Let us now hear the epigrammatic Frenchman, who sacrifices nearly as much to conciseness as the prosing Englishman loses by diffusion.

'Il y a donc des esprits de deux sortes. Les uns remarquent aisément les différences des choses, et ce sont les bons esprits. Les autres imaginent et supposent de la ressemblance entr' elles, et ce sont les esprits superficiels.' Rech. de la Vérité. Liv. ii. Seconde Partie, chap. ix. There are two sorts of minds. The one remark easily the differences of things, and these are the good minds [or understandings]. The other imagine and conjecture their resemblance, and these are the superficial minds.

Let us now listen to one who spoke as few others have spoken.

'Maximum et velut radicale discrimen ingeniorum, quoad philosophiam et scientias, illud est; quod alia ingenia sint fortiora et aptiora ad notandas rerum differentias; alia, ad notandas rerum similitudines. Ingenia enim constantia et acuta, figere contemplationes, et morari, et hærere in omni subtilitate differentiarum possunt. Ingenia autem sublimia, et discursiva, etiam tenuissimas et catholicas rerum similitudines, et cognoscunt et componunt. Utrumque autem ingenium facilè labitur in excessum, prensando aut gradus rerum, aut umbras.'

'That strain I heard was of higher mood!' exclaims Mr. Stewart, with an enthusiastic delight in which we fully participate. It is the original strain which has been much sung and variously altered, often deteriorated, never improved. We are afraid of marring it, else we would do it into English for the sake of the common reader. But let us hear it from the philosopher of Malmsbury. 'Natural wit consists principally in two things; celerity of imagining (that is swift succession of one thought to another), and steady direction to some approved end. On the contrary, a slow imagination makes the defect or fault of the mind which is commonly called dulness, stupidity, and sometimes by other names, that signify slowness of motion, or difficulty to be moved.

'This difference of quickness is caused by the difference of men's passions, who love and dislike, some one thing, some another; and therefore some men's thoughts run one way, some another, and are held to, and observe differently, the things that pass through their imagination. And as in this succession of men's thoughts there is nothing to observe in the things they think on, but either in what they are like one another, or in what they are unlike, or what they serve for, or how they serve to such a purpose; those that observe their similitudes, in case they be such as are but rarely observed by others, are said to have a good wit; by which is meant, in this connexion, a good fancy. But they that observe their differences, and dissimilitudes (which is called distinguishing, discerning, and judging), if such discerning be not easy, are said to have a good judgment. * * * The former, that is, fancy, without the help of judgment, is not commended as an excellence; but the latter, which is judgment, is commended by itself, without the help of fancy. Besides the discretion, or distinguishing, of times, places, and persons, necessary to a good fancy, there is required also a frequent application of his thoughts to their end; that is to say, to some use to be made of them. This done, he that has this excellence, will be easily fitted with similitudes, that will please not only by illustration of discourse, and adorning it with new and apt metaphors, but also by the rarity of their invention. But, without steadiness and direction to some end, a great fancy is one kind of madness; such as they have that, entering into any discourse, are snatched from their purpose by every thing that comes in thought, into so many, and so long digressions and parentheses, that they utterly lose themselves.' *Leviathan*, part I. chap. viii.

This, too, is not a bad strain, and more worthy of ranking with that of Bacon than either the epigram of Malebranche, or 'the very diffuse and wordy commentary upon it' by Locke. But what we intended chiefly was to bring into comparison, or rather contrast, the mode of expressing thought, as presented in the writings of Locke, and the writings of those from whom he borrowed; and to show how deficient he is in the use of words, or language, as the instrument or medium of knowledge. There is hardly a noted remark in the whole Essay on the Human Understanding which may not be compared or contrasted with some passage or other of some preceding author, particularly Hobbes, from whom he borrowed more than from all other authors put together, though he hardly ever mentions the name of his benefactor except in a way of reproach. This was, perhaps, more from fear than from ingratitude, or from the desire of appropriating to himself the fame of others. In his reply to the bishop of Worcester he says, 'I am not so well read in Hobbes and Spinoza as to be able to say what were their opinions in this matter; but possibly there may be those who will think your lordship's authority of more use than justly decried names.'

3. A third cause of the defects of the Essay of Mr. Locke has been already indicated, a want of originality, that is, want of intellectual adaptation to his undertaking. There is a manifest lack of unity of design, and much inconsistency among the parts, because they were taken from very different minds; and because, when taken from one and the same mind, as for example from that of Hobbes, the commentator either did not under stand his materials fully, or wished to work them up anew in a manner, and for a purpose, to which they were not suited; or to incorporate them with others wholly incongruous and heterogeneous. Take, for example, what he says about truth, at the opening of the fifth chapter of the fourth book. He adopts the statement of Hobbes, 'that truth properly belongs only to propositions;' but he instantly makes nonsense of it by adding, 'whereof there are two sorts, viz. mental and verbal; as there are two sorts of signs commonly made use of, viz. ideas and words.' What the author could intend to mean by ideas being commonly made use of as signs, it is impossible for us to conjecture. From such a hopeful beginning we have this edifying sequel.—'To form a clear notion of truth it is very necessary to consider truth of thought and truth of words distinctly one from another; but yet it is very difficult to treat of them asunder. Because it is unavoidable, in treating of mental propositions, to make use of words; and then the instances given of mental propositions cease immediately to be barely mental, and become verbal. For a mental proposition, being nothing but a bare consideration of the ideas as they are in our minds, stripped of names, they lose the nature of purely mental propositions as soon as they are put into words. And that which makes it yet harder to treat of mental and verbal propositions separately, is, that most men, if not all, in their thinkings and reasonings within themselves, make use of words instead of ideas; at least when the subject of their meditation contains in it complex ideas.'

Truly the case is not only hard, but desperate. What light or conduct of the understanding any man can find in statements like these we cannot divine; yet they are a fair specimen of very many of the statements contained in Mr. Locke's celebrated work. Such indistinctness, such confusion, or rather such absence of conceivable meaning, cannot possibly exist where a man has distinct thoughts in his mind, and writes only from his own understanding.

We might have remarked, under the former head, that it is not merely in putting words together that the author fails, which failure is generally connected with mental confusion, but in regard to single terms as signs of ideas, to use his own expression, he is almost habitually faulty. Take, for instance, his noted word idea, which is here, and there, and every where, throughout the essay. What can be more indefinite than this verbal Proteus? It seems to mean any thing, every thing, and nothing, by turns. And this, though a notable, is not a solitary example. There is hardly a word of much importance, and frequent recurrence, which is not applied in the same loose and careless manner. This of itself is a striking proof of want of adaptation, or qualification, for metaphysical research and discussion. There was nothing, Hobbes said (in a passage already quoted), that he distrusted so much as his diction or expression; but, notwithstanding all Mr. Locke's sage remarks and remonstrances on the subject, there seems to have been nothing that he so little distrusted.

What then, it may be said, are the merits of Mr. Locke?—We are fully disposed to allow them to be great, though not precisely such as have been generally assigned. He was a sincere lover of truth, and a most determined enemy to error and scholastic pretension and imposition. His work, though not remarkable for originality, consistency, or any thing like a luminous and instructive exposition of the subjects on which it professedly treats, contains many judicious remarks, brought together from various quarters; and, though it might have been so written as to do much more, it has certainly done much in clearing away the rubbish of a false and deceitful philosophy, or rather of learned jargon. The third book, though very diffuse and wordy, is still calculated to be highly useful to young enquirers: and it is impossible almost to estimate the good which the first book (unquestionably the ablest) has effected in banishing the Platonic mysticism and absurdity of innate ideas; which, so late as the times of Descartes, Leibnitz, Cudworth, and even Price, maintained a hold of minds much above intellectual mediocrity. It is true, some harm may have been done by the same book, in leading such as Condillac, Hartley, and many others, to assign too much to the senses and too little to the mind itself; yet we think it does not merit the treatment it has received from Reid, Stewart, and others of the same school.

The last-named author is sometimes rather indignant at what he calls the sophistry, and represents as of dangerous tendency, in the first book of the Essay: at other times he is not only extremely candid, but even eulogial towards the work as a whole. 'The enquiries,' he remarks in the first and second books, 'which are of a much more abstract, as well as scholastic, nature, than the sequel of the work, probably opened gradually on the author's mind in proportion as he studied his subject with a closer and more continued attention. They relate chiefly to the origin and to the technical classification of our ideas frequently branching out into collateral, and sometimes into digressive, discussions, without much regard to method or connexion. The third book (by far the most important of the whole), where the nature, the use, and the abuse of language, are so clearly and happily illustrated, seems, from Locke's own account, to have been a sort of after-thought; and the two excellent chapters on the association of ideas, and on enthusiasm (the former of which has contributed as much as any thing else in Locke's writings, to the subsequent progress of metaphysical philosophy) were printed, for the first time, in the fourth edition of the Essay.'

Respecting what Locke named, not very happily, association of ideas, such as are more just and generous to the memory of Hobbes than Mr. Stewart, admit that he was the first, at least in mo-

dern times, to state the mental fact or principle so much philosophised upon since his time (to what important purpose we hardly know notwithstanding Mr. Stewart's high-sounding language about the progress of metaphysical philosophy), and that he stated it in a far more striking and philosophical manner than his commentator.

The following is language far more loftily panegyrical both towards Mr. Locke and metaphysics than the writer of this article could sincerely adopt. 'But,' says Mr. Stewart, 'although these considerations render the two first books inferior in point of general utility to the two last, they do not materially detract from their merit, as a precious accession to the theory of the human mind. On the contrary, I do not hesitate to consider them as the richest contribution, of well-observed and well-described facts, which was ever bequeathed to this branch of science by a single individual; and as the indisputable (though not always acknowledged) source of some of the most refined conclusions, with respect to the intellectual phenomena which have been since brought to light by succeeding inquirers.'

The following perhaps may be regarded as a beautiful specimen of what we have failed in towards Mr. Locke:—

'After the details given by Locke himself, of the circumstances in which his Essay was begun and completed, more especially after what he has stated of 'the discontinued way of writing,' imposed on him by the avocations of a busy and unsettled life, it cannot be thought surprising, that so very little of method should appear in the disposition of his materials; or that the opinions which, on different occasions, he has pronounced on the same subject should not always seem perfectly steady and consistent. In these last cases, however, I am inclined to think that the inconsistencies, if duly reflected on, would be found rather apparent than real. It is but seldom that a writer, possessed of the powerful and upright mind of Locke, can reasonably be suspected of stating propositions in direct contradiction to each other. The presumption is, that, in each of these propositions, there is a mixture of truth, and that the error lies chiefly in the unqualified manner in which the truth is stated; proper allowances not being made, during the fervour of composition, for the partial survey taken of the objects from a particular point of view. Perhaps it would not be going too far to assert, that most of the seeming contradictions which occur in authors animated with a severe love of truth, might be fairly accounted for by the different aspects which the same objects presented to them upon different occasions. In reading such authors accordingly, when we meet with discordant expressions, instead of indulging ourselves in the captiousness of verbal criticism, it would better become us carefully and candidly to collate the questionable passages; and to study so to reconcile them, by judicious modifications and corrections, as to render the oversights and mistakes of our illustrious guides subservient to the precision and soundness of our own conclusions. In the case of Locke it must be owned, that this is not always an easy task, as the limitations of some of his most exceptionable propositions are to be collected, not from the context, but from different and widely separated parts of his essay.'

We leave our readers to judge of the soundness of the above criticism; but we thought it curious and worthy of insertion as a kind of contrast to our own; and we wished that Locke might have some chance of fair play with us.

In speaking of the celebrity which the Essay on the Understanding so soon acquired, the same writer adds very justly, 'something I suspect must be ascribed to the political importance which Mr. Locke had previously acquired as the champion of religious toleration, as the great apostle of the revolution, and as the intrepid opposer of a tyranny which had recently been overthrown.' No doubt all this did much for the work; and a high reputation once obtained is sure to remain unless put down by some powerful re-action of opinion. Another circumstance was the magnitude of the work; it seemed a complete body of metaphysics. A third favorable circumstance was the modesty and amicableness of the author; in this respect he was a complete contrast to his metaphysical master. But it is probable that the celebrity of the essay is owing chiefly to its indefinite character. It has been justly observed that 'most readers delight to repose in generalities.' The author so often quoted already, when speaking of Leibnitz, remarks with more than usual acuteness, 'the phraseology is so indeterminate, that it may be interpreted in various senses essentially different from each other. Whether this vagueness of language was the effect of artifice, or of real vagueness in the author's notions, may perhaps be doubted; but that it has contributed greatly to extend his reputation, among a very numerous class of readers, may be confidently asserted.'

As almost all sects, and parties, and persons in Britain have vied with one another in lauding Locke; so his fame has been great on the continent, particularly in France. According to Voltaire he is the Hercules of metaphysics, who has fixed the boundaries of the human understanding. Locke est l'Hercule de la metaphysique, qui a posé les bornes de l'esprit humain. This is sublime, but another passage of the same celebrated Voltaire is quite the marvellous. 'Locke alone has developed the human understanding in a work where there is nothing but truths, and what renders the work perfect all its truths are luminous. Locke seul a developpé l'entendement humain dans un livre où il n'y a que des vérites; et ce qui rend l'ouvrage parfait, toutes ces vérités sont claires.' Is there here any evidence that this smart Frenchman ever read the perfect work concerning the human understanding? Or need we wonder at the unmeasured praise of Locke after this?

Condillac is to be regarded as the French interpreter and commentator of Locke; and it is universally allowed that he has performed his task with great perspicuity and eloquence. But he has not given the whole of Locke and nothing but Locke; for he has so much transmuted the English doctrines about the human understanding, that it would be more proper to call them after Gassendi; and some French writers are now

inclined to restore the long alienated fame of the true philosophy of the human mind to its rightful owner; as has already appeared by a quotation from Degerando. According to Condillac all our ideas, thoughts, mental operations, and emotions, are nothing but transformed sensations. What he means by transformation he has not defined. 'If we consider,' says he, 'that to remember, to compare, to judge, to distinguish, to imagine, be astonished, to have abstract ideas, to have ideas of number and duration, to know truths, whether general or particular, are but so many modes of being attentive; that to have passions, to love, to hate, to hope, to fear, to will, are but so many different modes of desire; and that attention in the one case, and desire in the other case, of which all these feelings are modes, are themselves, in their origin, nothing more than modes of sensation, we cannot but conclude that sensation involves in it all the faculties of the soul.'—*Traité des Sensations*, part I. chap. vii.

This is a very short and simple process no doubt. The soul and all its faculties are resolvable into the five senses, and there is an end of the matter. Locke allowed that there was something of a mind or soul to begin, with analogous to a sheet of white paper, and Hobbes thought it rather analogous to a slate. But according to Condillac there is nothing whatever beside or beyond, or distinct from the senses, or their agency, called sensation; all that is supposed to be distinct from this is nothing but itself transformed like a harlequin into another character when performing a different part. Whatever we may think of this doctrine, says Dr. Brown, Lecture 33, as true or false, ingenious or absurd, it seems, at least, scarcely possible that we should regard it as the doctrine of Locke —of him who sets out with a primary division of our ideas, into two distinct classes, one class of which alone belongs to sensation; and who considers even this class of our mere ideas, not as involving all the operations of the mind with respect to them, but only as the objects of the mind in these various operations, as being what we compare, not the very feelings of our comparison itself, the inducements to passion, not what constitutes any of our passions, as a state, or series of states of the mind. To render the paragraph quoted from Condillac at all accordant with the real doctrine of Locke, it would be necessary to reverse it in almost every proposition which it involves.

We will not detain the reader longer with Condillac, who may be regarded, however, as standing at the head of the metaphysicians on the continent who consider themselves the disciples of the metaphysical Hercules of England. According to both Mr. Stewart and Dr. Brown they have all misunderstood their master's doctrine; whether this proves their dulness or perversity, or his unfathomable profundity, or dazzling brightness, the reader must judge for himself.

HARTLEY.

Dr. Hartley is known, and was for a time, to some extent at least, admired as the author of a work entitled Observations on Man; in which he propounded a very fanciful theory of vibration for the purpose of explaining the operations of the mind. Dr. Brown has expended some very unnecessary refutation on the vibrating theory in one of his lectures; especially as he states that it 'has now fallen into merited disrepute even with those who are inclined, in other respects, to hold in very high estimation the merits of Hartley as an intellectual analyst.' 'His followers, he continues, have generally been extravagant admirers of his philosophical genius, which I own seems to me to be very opposite to the genius of sound philosophy. That there is considerable acuteness, however, displayed in his work, and that it contains some successful analyses of complex feelings, I am far from denying; and, as intellectual science consists so much in the analysis of the complex phenomena of thought, its influence in this respect has unquestionably been of service, in promoting that spirit of free enquiry, which, in a science that presents no attraction to the senses, is so easily laid asleep, or at least so readily acquiesces, as if to justify its indolence, in the authority of great names, and of all that is ancient in error and venerable in absurdity. But though the influence of his philosophy may have been of service in this respect, the advantage which has perhaps flowed from it in this way must have been inconsiderable compared with the great evil which has unquestionably flowed from it in another way, by leading the enquirer to acquiesce in remote analogies, and to adopt explanations and arrangements of the phenomena of mind, not as they agree with the actual phenomena, but as they chance to agree with some supposed phenomena of our material part.'

Dr. Hartley has given the same general account of the origin of ideas with Condillac; but so far from claiming the sanction of Locke's authority he points out the difference between his own opinion and that expressed by the author of the Essay on the Understanding. 'It may not be amiss (he remarks in the introduction to his work) here to take notice how far the theory of these papers has led me to differ in respect of logic from Mr. Locke's excellent Essay on the Human Understanding, to which the world is so much indebted for removing prejudices and incumbrances, and advancing real and useful knowledge. First, then, it appears to me, that all the most complex ideas arise from sensation, and that reflection is not a distinct source, as Mr. Locke makes it.'

The materialists and necessitarians have a sort of natural affection for Hartley; and Dr. Priestley speaks in very admiring strains of the author of the vibratory and vibratiuncle theory. 'Something was done,' (he says, remarks on Reid, Beattie and Oswald), 'in this field of knowledge by Descartes, very much by Mr. Locke, but most of all by Dr. Hartley, who has thrown more useful light on the theory of mind, than Newton did upon the theory of the natural world.' What with one light and another that has been thrown upon the theory of mind, the northern lights both Scottish and German, and the effulgent radiance of Locke, Condillac, and Hartley, we might have expected of course to be dark, as we are, through excess of brightness.

According to Mr. Stewart the theory of Hartley seems to be fast passing into oblivion: 'the temporary popularity which it enjoyed in this country having in a great measure ceased with the life of its zealous and indefatigable apostle Dr. Priestley.' Yet one of his co-operators in the Supplement to the Encyclopædia Britannica, the writer of the article Education, is almost as ardent an admirer of Hartley as Priestley himself. 'It is surprising,' he says, 'how little the author of the vibratory theory has left unaccomplished.' It is truly astonishing too, what Condillac, Helvetius, and Cabanis have done; as to Locke, of course, the Hercules of metaphysics, none but Voltaire is fit to tell his metaphysical exploits.

HUME.

Mr. Hume commenced his literary career in the twenty-fifth year of his age, by writing a work entitled a Treatise of Human Nature, suggested no doubt by that of Hobbes, bearing essentially the same title. The reception of this first work was sufficient to have extinguished the ambition of authorship in a less ardent mind. 'Never literary attempt was more unfortunate,' says the author; 'it fell dead-born from the press without reaching such distinction as even to excite a murmur among the zealots.' He afterwards endeavoured to adapt the contents of the abortive publication to the public taste by modifying them anew and presenting them in the popular and fashionable form of essays. According to Mr. Stewart, with whom every thing save and except pure Hobbism, is metaphysical optimism, the Treatise of Human Nature 'has contributed, either directly or indirectly, more than any other single work, to the subsequent progress of the Philosophy of the Human Mind.' What with the sure law of continuity and infinite progression, the Philosophy of the Human Mind will doubtless at last reach infinitesimal perfection in the arrangement of well authenticated facts, refined speculations, and all the genera and species of intellectual phenomena.

The objects contemplated in the Treatise of Human Nature are thus presented by the author: ''Tis evident that all the sciences have a relation, greater or less, to human nature, and that, however wide any of them may seem to run from it, they still return back by one passage or another. Even mathematics, natural philosophy, and natural religion, are in some measure dependent on the science of man, since they lie under the cognizance of men, and are judged of by their powers and faculties. * * * If, therefore, the science of mathematics, natural philosophy, and natural religion, have such a dependence on the knowledge of man, what may be expected in the other sciences, whose connexion with human nature is more close and intimate? The sole end of logic is to explain the principles and operations of our reasoning faculty, and the nature of our ideas: morals and criticism regard our tastes and sentiments, and politics consider men as united in society and dependent on each other. * * * Here, then, is the only expedient from which we can hope for success in our philosophical researches, to leave the tedious lingering method which we have hitherto followed, and, instead of taking now and then a castle or village on the frontier, to march up directly to the capital or centre of these sciences, to human nature itself; which being once masters of we may every where else hope for an easy victory. From this station we may extend our conquests over all those sciences which more intimately concern human life, and afterwards proceed at leisure to discover more fully those which are the objects of pure curiosity. There is no question of importance whose decision is not comprised in the science of man; and there is none which can be decided with any certainty before we become acquainted with that science. In pretending, therefore, to explain the principles of human nature, we in effect propose a complete system of the sciences, built on a foundation almost entirely new, and the only one upon which they can stand with security.'

See, the conquering hero come! A precocious Kant! A second Hercules of metaphysics, mightier far than the first! But let us hear this wonderful projector, so pregnant with metaphysical wisdom, disburthen himself of his philosophical inspiration.

'And, as the science of man is the only solid foundation for the other sciences, so the only solid foundation we can give to this science itself must be laid on experience and observation. 'Tis no astonishing reflection to consider, that the application of experimental philosophy to moral subjects should come after that to natural, at the distance of above a whole century; since we find, in fact, that there was about the same interval betwixt the origin of the sciences; and that, reckoning from Thales to Socrates, the space of time is nearly equal to that betwixt my lord Bacon and some late philosophers in England, who have begun to put the science of man on a new footing, and have engaged the attention and excited the curiosity of the public.'

This is all very lofty and very wonderful, and no doubt mortified the pride of the author to the last hour of his life. Hence he was always peevish and querulous on the subject of this juvenile work as he terms it. 'Several writers,' he says, 'who have honored the author's philosophy with answers, have taken care to direct all their batteries against that juvenile work, which the author never acknowledged, and have affected to triumph in any advantage which they imagined they had gained over it: a practice very contrary to all rules of candor and fair dealing, and a strong instance of those polemical artifices which bigoted zeal thinks itself authorised to employ. Henceforth the author desires that the following pieces may alone be regarded as containing his philosophical sentiments and principles.' 'I was carried away, by the heat of youth and invention, to publish too precipitately. So vast an undertaking, planned before I was one-and-twenty, and composed before twenty-five, must necessarily be very defective.—I have repented my haste a hundred and a hundred times.'

The youthful projector or aspiring adventurer in the wonder-working science of man, not succeeding in his ambitious expectations in marching up to the capital,—in extending his conquests,—in acquiring an easy victory,—in

pretending to explain the principles of human nature, and proposing a complete system of the sciences, built on a foundation almost entirely new, and the only one on which they can stand with security, became desperate. Retaining, like Lucifer after his fall, however, an insatiable ambition of renown, and having a rooted antipathy to religion, he thought he might be a Hercules of scepticism, and destroy all such superstitious monsters as the vulgar principles of human belief. Accordingly, in turning sceptic, and champion of scepticism, he turned sophist also; for the one never yet existed, in any thing like perfection, without the other. Notwithstanding all Mr. Stewart's tenderness, or rather favoritism, towards Mr. Hume (not very intelligible but on the supposition of nationality), the author of the first treatise of human nature is in every respect honorable, and, hated as he is, lovely when compared with the author of the second. The first cannot, in any fairness or justice, be pronounced a sophist.

The following statement by Mr. Stewart is upon the whole just, and it is sufficiently candid or rather partial, towards Hume:—'The fundamental principles from which Mr. Hume sets out differ more in words than in substance [he was ambitious of standing alone and seeming to differ even from those with whom he essentially agreed,—if indeed he agreed with any one fixed principle] from those of his immediate predecessors. According to him, all the objects of our knowledge are divided into two classes, impressions and ideas: the former, comprehending our sensations, properly so called, and also our perceptions of sensible qualities [two things betwixt which Mr. Hume's system does not lead him to make any distinction]; the latter, the objects of our thoughts when we remember or imagine, or in general exercise any of our intellectual powers on things which are past, absent, or future. These ideas he considers as copies of our impressions, and the words which denote them as the only signs entitled to the attention; every word professing to denote an idea, of which the corresponding impression cannot be pointed out, being ipso facto unmeaning and illusory. The obvious result of these principles is that, what Mr. Hume calls impressions, furnish, either immediately or mediately, the whole materials about which our thoughts can be employed; a conclusion coinciding exactly with the account of the origin of our ideas borrowed by Gassendi from the ancient Epicureans. With this fundamental principle of the Gassendists Mr. Hume combined the logical method recommended by their great antagonists the Cartesians; and, what seems still more remote from his Epicurean starting-ground, a strong leaning to the idealism of Malebranche and of Berkeley. Like Descartes, he began with doubting of every thing, but he was too quick-sighted to be satisfied, like Descartes, with the solutions given by that philosopher of his doubts. On the contrary, he exposes the futility, not only of the solutions proposed by Descartes himself, but of those suggested by Locke and others among his successors; ending at last where Descartes began, in considering no one proposition as more certain, or even as more probable, than another. That the proofs alleged by Descartes, of the existence of the material world, are quite inconclusive, had been already remarked by many. Nay it had been shown, by Berkeley and others, that, if the principles be admitted on which Descartes, in common with all philosophers, from Aristotle downwards, proceeded, the existence of the material world is impossible. A few bold thinkers, distinguished by the name of Egotists, had gone still farther than this, and had pushed their scepticism to such a length as to doubt of every thing but their own existence. According to these the proposition cogito ergo sum is the only truth which can be regarded as absolutely certain. It was reserved for Mr. Hume to call in question even this proposition, and to admit only the existence of impressions and ideas. To dispute against the existence of these he conceived to be impossible, inasmuch as they are the immediate subjects of consciousness. But, to admit the existence of the thinking and percipient I, was to admit the existence of that imaginary substance called mind, which, according to him, is no more an object of human knowledge than the imaginary and exploded substance called matter.

'From what has already been said it may be seen, that we are not to look in Mr. Hume's treatise for any regular or connected system. It is neither a scheme of materialism nor a scheme of spiritualism; for his reasonings strike equally at the root of both these theories. His aim is to establish a universal scepticism, and to produce in the reader a complete distrust of his own faculties. For this purpose he avails himself of the data assumed by the most opposite sects, shifting his ground skilfully from one position to another, as best suits the scope of his present argument. With the single exception of Bayle he has carried this sceptical mode of reasoning farther than any other modern philosopher. Cicero, who himself belonged nominally to the same school, seems to have thought, that the controversial habits imposed on the academical sect, by their profession of universal doubt, required a greater versatility of talent and fertility of invention than were necessary for defending any particular system of tenets; and it is not improbable that Mr. Hume, in the pride of youthful genius, was misled by this specious but very fallacious idea. On the other hand, Bayle has the candor to acknowledge that nothing is so easy as to dispute after the manner of the sceptics; and to this proposition every man of reflection will find himself more and more disposed to assent as he advances in life. It is experience alone that can convince us how much more difficult it is to make any real progress in the search after truth, than to acquire a talent for plausible disputation.

'That this spirit of sceptical argument has been carried to a most pernicious excess in modern Europe, as well as among the ancient academics, will be now very general allowed; but, in the form in which it appears in Mr. Hume's Treatise, its mischievous tendency has been more than compensated by the importance of those results for which it has prepared the way. The principles which he assumes were sanctioned in common by Gassendi, by Descartes, and by

Locke; and from these, in most instances, he reasons with great logical accuracy and force. The conclusions to which he is thus led are often so extravagant and dangerous, that he ought to have regarded them as a proof of the unsoundness of his data; but, if he had not the merit of drawing this inference himself, he at least forced it so irresistibly on the observation of his successors as to be entitled to share with them in the honor of their discoveries. Perhaps, indeed, it may be questioned if the errors which he adopted from his predecessors would not have kept their ground till this day had not his sagacity displayed so clearly the consequences which they necessarily involve. It is in this sense that we must understand a compliment paid by the ablest of his adversaries, when he says, that Mr. Hume's premises often do more than atone for his conclusions.'

'The bias of Mr. Hume's mind to scepticism seems to have been much encouraged, and the success of his sceptical theories in the same proportion promoted, by the recent attempts of Descartes and his followers to demonstrate self-evident truths—attempts which Mr. Hume clearly perceived to involve, in every instance, that sort of paralogism which logicians call reasoning in a circle. The weakness of these pretended demonstrations is triumphantly exposed in the Treatise of Human Nature; and it is not very wonderful that the author, in the first enthusiasm of his victory over his immediate predecessors, should have fancied that the inconclusiveness of the proofs argued some unsoundness in the propositions which they were employed to support. It would, indeed, have done still greater honor to his sagacity if he had ascribed this to its true cause, the impossibility of confirming, by a process of reasoning, the fundamental laws of human belief. From that strong sceptical bias which led this most acute reasoner, on many important questions, to shift his controversial ground according to the humor of the moment, one favorable consequence has resulted, that we are indebted to him for the most powerful antidotes we possess against some of the most poisonous errors of modern philosophy.'

That Mr. Hume was an acute reasoner or rather arguer, and that he has done some good which he never intended, we willingly admit; but take it altogether we hardly know of an intellectual character for which we feel less respect than for his.

REID, OSWALD, BEATTIE, AND STEWART.

We class these names together because they are identified with what is termed the Scotch metaphysics; but we mean to take no other notice of Oswald and Beattie. Even Mr. Stewart is almost ashamed to own them, with all their boasted common sense. The following dexterous turn, when it seemed impossible to avoid saying something of their merits, is amusing: 'Of the other works by Scottish metaphysicians, which appeared soon after the enquiry into the Human Mind, I have not left myself room to speak; I know of none of them from which something important may not be learned; while several of them (particularly those of Dr. Campbell) have struck out many new and interesting views. To one encomium all of them are well entitled, that of aiming steadily at the advancement of useful knowledge and of human happiness. But the principles on which they have proceeded have so close an affinity to those of Dr. Reid, that I could not, without repeating over what I have already said, enter into any explanation concerning their characteristical doctrines.'

We wish indeed that, with all their good intentions, their manner of opposing scepticism (and the remark applies also to Dr. Reid and Mr. Stewart) had been more calculated to do good and less such as to do harm. We can speak feelingly on the subject when we say that the remark applied by Mr. Stewart to the scheme of optimism is but too applicable to the scheme of common sense as treated of by Oswald, Beattie, —we will not name any more. 'The success of his attempt (Voltaire's) was much aided by the confused and inaccurate manner in which the scheme of optimism had been recently stated by various writers, who in their zeal to vindicate the ways of God to men, had been led to hazard principles more dangerous in their consequences than the prejudices and errors it was their aim to correct.'

But it is with Dr. Reid, and his disciple and commentator Mr. Stewart, as inductive philosophers of the human mind, that we have to do. Somewhat more than twenty years ago the former appeared to the writer of this paper a perfect Socrates, and the latter as perfect a Plato, delivering in divine eloquence the wisdom of his sage master 'the experimental father of the true theory of the human mind;' but time makes great changes. The venerable father of the Scottish metaphysics, may, between Mr. Stewart (who with all his partiality has detected in him not a few mistakes) and Dr. Brown, be compared to the old gentleman in the hands of his two wives who made him quite bald and bare, one objecting to the black and the other to the white hairs on his head. Mr. Stewart, indeed, is gentle and forbearing, for real affection is always unwilling to offend or to hurt; but Dr. Brown pulls up by the roots most unmercifully all Dr. Reid's claims to admiration or even respect as an inductive philosopher: he employs three or four long, logical, eloquent, lectures in proving that Dr. Reid's grand intellectual discovery or metaphysical achievement was, after all that had been said of its wonderful importance, both by himself and his disciples, nothing but an egregious blunder.

The following is the manner in which he opens his destructive battery upon the reputation of the Hercules of the Scottish metaphysics; who it was supposed had vanquished all the giants, and annihilated all the monsters of idealism. 'While by philosophers in one part of the island, Dr. Reid's merits seem to have been unjustly undervalued, I cannot but think also that, in his own country, there has been an equal, or rather a far greater tendency to over-rate them,—a tendency arising in part from the influence of his academic situation, and his amiable personal character, partly, and in a very high degree, from the general regard for the moral and religious objects

which he uniformly had in view, as contrasted with the consequences that were supposed to flow from some of the principles of the philosopher whose opinions he particularly combated; and partly also, I may add, from the eloquence of his illustrious pupil and friend and biographer, whose understanding, so little liable to be biassed by any prejudices but those of virtue and affectionate friendship, has yet, perhaps, been influenced in some degree by those happy and noble prejudices of the heart, and who, by the persuasive charms both of his lectures and of his writings, could not fail to cast, on any system of opinions which he might adopt and exhibit, some splendor of reflection from the brilliancy of his own mind.

'The genius of Dr. Reid does not appear to me to have been very inventive, nor to have possessed much of that refined and subtile acuteness, which, capable as it is of being abused, is yet absolutely necessary to the perfection of metaphysical analysis.

'It is chiefly on his opinions, in relation to the subject at present under our view, that his reputation as an original thinker rests. Indeed it is on these that he is inclined himself to rest it. In a part of a letter to Dr. Gregory, preserved in Mr. Stewart's Memoir, he considers his confutation of the ideal system of perception as involving almost every thing which is truly his. 'I think there is hardly any thing that can be called mine,' he says, 'in the philosophy of mind which does not follow with ease from the detection of this prejudice.' Yet there are few circumstances, connected with the fortune of modern philosophy, that appear to me more wonderful than that a mind like Dr. Reid's, so learned in the history of metaphysical science, and far too honorable to lay claim to praise to which he did not think himself fairly entitled, should have conceived that, on the point of which he speaks, any great merit, at least any merit of originality, was justly referrible to him particularly. Indeed, the only circumstance more wonderful is, that the claim thus made by him, should have been so readily and generally admitted.'

The claim had been long disallowed (notwithstanding all the strenuous and indefatigable efforts of the illustrious pupil), by competent judges beyond the Scottish boundaries; but it was a kind of revolution for it to be overthrown in the university of the Scottish capital, and in the very chair so long filled by Dr. Reid's disciple and commentator. No doubt, however, according to Mr. Stewart's metaphysical optimism, or sure and certain hope of the intellectual philosophy, this was, with Mr. Hume's daring scepticism, working forward the science of the human mind.

It is not necessary to detain the reader longer with the author of an Enquiry into the Human Mind, and Essays on the Intellectual and Active Powers of Man. His glory is departed we suspect from even the Scottish universities; whose future metaphysical professors will probably be as shy of owning him as Mr. Stewart is of embracing affectionately the intellectual memory of his compeers Oswald and Beattie. This sage, as Dr. Currie and Mr. Stewart were wont to designate him, now stands convicted of 'much zealous blundering' (to give Dr. Brown's words) in professing to confute what existed nowhere but as phantoms of his own confused brain.

Concerning 'his illustrious pupil' we would rather not speak our mind if we could well be silent, as we cannot sincerely characterise him as an inductive philosopher of the human mind in flattering terms, and should be unwilling to wound the feelings of an aged and excellent individual. But we think it very unfortunate for his intellectual reputation that his name is at all identified with the metaphysical history of the nineteenth century; for, as expressed by a contemporaneous critic, he has certainly 'mistaken his forte.' Few men perhaps who have been thrown by circumstances into abstract enquiries and abstruse speculations, have possessed less of metaphysical adaptation for them from either nature or art: and we fear that his secondary claims as an elegant scholar and accomplished literary man, which, standing alone, might have been well supported and have long endured, will fall with his primary pretensions. We will not discuss the merits of his intellectual faculties and powers (to use a sort of favorite expression of his own), or of his productions considered either in a mere literary or in a philosophical view; for, though not afraid to blame, we would rather praise. But there are two points on which we cannot forbear expressing our opinion. The one is what we consider the philosophic bigotry of Mr. Stewart, and the other is what we call his philosophic pretension.

We have availed ourselves very freely of his two dissertations in the supplement to the Encyclopædia Britannica, which display the extent and the diversity of his reading; and we feel grateful for the trouble they saved and the assistance they afforded us. At the same time we must observe that they contain a very great proportion not only of unsound, but of unfair criticism. If authors happen to hold opinions deemed by Mr. Stewart adverse to what he considers the true theory of mind or to natural religion (it would not be decorous perhaps to manifest a spark of zeal for revealed religion), whatever be their genius or intellectual rank, they would seem fit objects for unsparing hostility, we had almost said relentless persecution. He is tolerant and tender indeed towards Mr. Hume, as already noticed; but witness his unceasing hostility towards Gassendi and Hobbes, and all the Epicureans as he designates them; witness his conduct towards even Locke, notwithstanding all his courtly caution and complimentary courtesy, for he accuses him of sophistry; witness his remarks on such disciples of Locke as Law, Watson, and the ingenious Tucker, of whom he thus writes:—'Of an author whom Dr. Paley has honored with so very warm a eulogy, it would be equally absurd and presumptuous to dispute the merits. Nor have I any wish to detract from the praise here bestowed on him as an original thinker and observer. I readily admit, also, his talent for illustration, although it sometimes leads him to soar into bombast, and more frequently to sink into buffoonery. As an honest enquirer after moral and religious truth he is entitled to the most

unqualified approbation. But I must be permitted to add that, as a metaphysician, he seems to me much more fanciful than solid; and at the same time to be so rambling, verbose, and excursive (was it prudent to cast such epithets?) as to be more likely to unsettle than to fix the principles of his readers.'

This is a favorable specimen, compared to much that might be brought forward. Mr. Stewart's antipathy seems to be in proportion to the originality of an author, if that author happen to be beyond the pale of his own sect, or not included within the circle of metaphysical orthodoxy. The odium theologicum has long been proverbial; and we say it with a sigh, for we have felt what we express, that the odium metaphysicum of Oswald, Beattie, Reid, and Stewart, has done more serious mischief than all their shallow metaphysics and blundering reasonings. The writer of this will not yield to Mr. Stewart in religious belief, or in deep sense of the importance of religion and morality; and his regret is, that religious and moral principles should be wounded by their professed friends, or betrayed by their weak advocates.

The second charge which we have to prefer against Mr. Stewart is that of philosophic assumption and pretension. Indeed we cannot believe that he is aware of what we are now complaining of, to the extent to which it pervades his writings, but that it has silently grown up with him into an inveterate but offensive habit. Still the incessant recurrence of such high sounding, quackish looking, expressions, as intellectual data, intellectual phenomena, true theory of mind, inductive philosophy of the mind, experimental philosophy of the mind, the science of the mind, intellectual philosophy, &c. &c. &c., is perfectly annoying. If Mr. Stewart be not the profoundest metaphysician, the greatest intellectual discoverer, the acutest intellectual analyst, the most successful observer of mental phenomena that any age or country has produced, he will at least descend to posterity, and be the wonder of all succeeding times as the greatest inventor and improver of metaphysical grandiloquentia that the world ever saw. All that went before him was tame and timid and sheepishly modest, when compared to him. If Descartes the father of the experimental philosophy of the mind, or Malebranche who did so much for it as an inductive science, or such Epicureans as Gassendi, or old Hobbes, or Hercules himself, were to come back to these lower intellectual regions, they would stare with astonishment at our new nomenclature.

Hobbes entitled his celebrated Libellum (which Mr. Stewart thinks with Addison, and other great judges, the best of all his works), Human Nature; Malebranche called his work the Search of Truth; Locke, with a degree of modesty which incurred the charge of a misnomer, denominates his Herculean labor, an Essay concerning Human Understanding; Hume entitled his juvenile production (in which, as we have seen, there is something of the mock heroic about the science of man, whether sincere or insidious) a Treatise of Human Nature; that sage, or Socrates, of the common-sense metaphysics, Dr. Reid, was so unassuming as to be content with such humble titles as an Enquiry into the Human Mind, Essays on the Intellectual and Active Powers of Man. It was reserved for Mr. Dugald Stewart to have all the glory of being the first author and professor of the Philosophy of Mind; and of rendering intellectual science, intellectual phenomena, and many similar philosophic forms of speech concerning metaphysics, as familiar in our mouths as household words In this respect he thought himself no doubt a metaphysical benefactor; judging that (to quote his own words, first dissertation, p. 59), 'above all, whatever tends to embody, in popular forms of expression, the ideas and feelings of the wise and good, augments the natural powers of the human understanding, and enables the succeeding race to start from a higher ground than was occupied by their fathers.'

Doubtless so far as grandiloquence is embodied in popular speech, and concerned in augmenting the natural powers of the understanding, the succeeding race will start from high ground indeed; they will at least be so much mounted towards the etherial regions as to be fairly up among the clouds, on the alpine summits of lofty phraseology. But we are sick of the nauseous topic, and will quit it, we hope for ever, by quoting another passage from Mr. Stewart, which requires very little alteration to adapt it as completely to himself and his boasted science, and his metaphysical coadjutors, as if it had been 'made for them.' 'The fundamental principles of Puffendorff (first dissertation, p. 130) possess little merit in point of orginality, being a sort of medley of the doctrine of Grotius, with some opinions of Hobbes; but his book is entitled to the praise of comparative conciseness, order, and perspicuity; and accordingly came very generally to supplant the treatise of Grotius, as a manual or institute for students, notwithstanding its immense inferiority in genius, in learning, and in classical composition. The authors who in different parts of the continent have since employed themselves in commenting on Grotius and Puffendorff [substitute Locke and Reid, and understand for the authors or lecturers, Scottish professors], or in abridging their systems, or in altering their arrangements, are innumerable; but, notwithstanding all their industry and learning, it would be very difficult to name any class of writers whose labors have been of less utility to the world. The same ideas are constantly recurring in an eternal circle; the opinions of Grotius and of Puffendorff, where they are at all equivocal, are anxiously investigated, and sometimes involved in additional obscurity; while, in the mean time, the science of natural jurisprudence [substitute human mind], never advances one single step; but, notwithstanding its recent birth, seems already sunk into a state of dotage.'

All this, when applied to Scottish metaphysics, is strikingly just and happily expressed. It is now ascertained that the opinion of Dr. Brown concerning Mr. Stewart as a metaphysician was essentially the same as that expressed of Dr. Reid; and that, in demolishing the claims of the one, he was, without avowedly doing it, actually

battering down the pretensions and erections of the other. Dr. Brown's book may then (as Montesquieu said of that of Cervantes), be considered the best of the kind yet produced in Scotland, not only abstractedly viewed, but because it so effectually exposes the absurdity of all the rest. He says, in a letter to Mr. Erskine (Life of Dr. Brown, p. 195), 'I was very much constrained, as you may believe, by the unpleasantness of differing so essentially from Mr. Stewart, on many of the principal points. But I conceived that it would be more honorable to state at once my own opinions, than to seem to introduce them afterwards in other years; and Dr. Reid's name fortunately served every purpose, when I had opinions to oppose in which Mr. Stewart perhaps coincided. I got off, therefore, pretty well in that way; though I must confess that it was one of the most unpleasant circumstances attending my situation.'

For Mr. Stewart, as an elegant scholar, an excellent man, a friend of civil and religious liberty, and of human improvement and happiness, we have the highest respect and regard; but, next to sophistry, we do hate, from our inmost soul, all learned and philosophic pretensions and cant. These are the entities towards which our uncompromising and unsparing hostility is directed; and, if we could encounter them in a state of pure metaphysical abstraction, we would gladly escape from the unwelcome and painful task of dealing with them in their concrete form. If they have no existence in connexion with Mr. Stewart—if they are not embodied in his writings (and we have no personal knowledge of him), we have wronged him, and would, upon convincement of our guilt, willingly make any atonement in our power;—but even in this case we have sinned, not wantonly, but ignorantly: it was in truth with extreme and very painful reluctance that we wrote what we have written.

As the expressions, experimental induction, &c., 'are constantly recurring in an eternal circle,' throughout the Dissertations of Mr. Stewart, we quote the following just remark from those of Mr. Playfair which are so admirable in almost every respect. 'The experimentum crucis,' says Mr. Playfair, 'is of such weight in matters of induction, that in all those branches of science where it cannot be easily resorted to (as agriculture, medicine, political economy, &c.)—[that metaphysics is included, no reasonable person can doubt], there is often a great want of conclusive evidence. Hence the great difficulty of separating the causes, and allotting to each its due proportion of the effect. Men deceive themselves in consequence of this continually, and think they are reasoning from facts and experience, when in reality they are only reasoning from a mixture of truth and falsehood. The only end answered by facts, so incorrectly apprehended, is that of making error more incorrigible.'

THOMAS BROWN, M. D.

LATE PROFESSOR OF MORAL PHILOSOPHY IN THE UNIVERSITY OF EDINBURGH.

It is supposed that a medical course of study is favorable to metaphysical intellect. We lay no stress on this; though there is probably considerable tendency in the one to the other, as there is certainly a sort of natural connexion between the physical and metaphysical study of man; or between the physiology of the human frame, and what some have recently named the physiology of mind. Locke and Hartley, as well as Dr. Brown, were physicians. Dr. Brown, however, had a metaphysical bias before he studied medicine with a view to a profession. The latter no doubt acted powerfully, and in some respects favorably, on the former. There was another early, and which proved a permanent bias of his mind—which would seem at first sight not very favorable to, or compatible with the other, though it existed also in the singular mind of Hobbes—a poetic turn or tendency, if we may not call it genius. Certain it is, from both examples of the union of a metaphysical and a poetical bias, that, if the latter was not unfavorable to the former, the metaphysical was decidedly unfavorable to the poetical energy of the mind. We think that this might be easily and perhaps satisfactorily accounted for. This, however, is not our present business; suffice it to remark, that Brown, Hobbes, Bacon, (as all men possessed of high degrees of intellectual vigor) would seem to have been as truly possessed ab origine of the poetical genius (that is a powerful and active imagination) as Shakspeare, Milton, Homer, and Virgil, but subsequent circumstances made the ultimate distinction as to intellectual character. We proceed to give some account of Dr. Brown's lectures.

The first is introductory; and we select from it the following remarks as the most essentially important. Having remarked on the futility and absurdity of the metaphysics of the schoolmen, he adds:—'The progress of intellectual philosophy may indeed, as yet, have been less considerable than was to be hoped under its present better auspices. But it is not a little to have escaped from a labyrinth, so very intricate and so very dark, even though we should have done nothing more than advance into sunshine and an open path, with a long journey of discovery still before us. We have at last arrived at the important truth, which now seems so very obvious a one, that the mind is to be known best by observation of the series of changes which it presents, and of all the circumstances which precede and follow these. * * * The mind, it is evident, may like the body to which it is united, or the material objects which surround it, be considered as a substance possessing certain qualities, susceptible of various affections or modifications, which, existing successively as momentarily states of the mind, constitute all the phenomena of thought and feeling. The general circumstances in which these changes of state succeed each other, or, in other words, the laws of their succession, may be pointed out, and the phenomena arranged in various classes, according as they may resemble each other, in the circumstances that precede or follow them, or in other circumstances of obvious analogy. There is, in short, a science that may be termed mental physiology, as there is another science relating to the structure and offices of our corporeal frame, to

which the term physiology is more commonly applied; and as by observation and experiment we may endeavour to trace those series of changes which are constantly taking place in our material part, from the first moment of animation to the moment of death; so, by observation, and in some measure also by experiment, we endeavour to trace the series of changes that take place in the mind, fugitive as these successions are, and rendered doubly perplexing by the reciprocal combinations into which they flow. * * * *

'There is a philosophic spirit which is far more valuable than any limited acquirements of philosophy; and the cultivation of which, therefore, is the most precious advantage that can be derived from the lessons and studies of many academic years; a spirit which is quick to pursue whatever is within the reach of human intellect; but which is not quick to discern the bounds that limit every human enquiry, and which, therefore, in seeking much, seeks only what man may learn: which knows how to distinguish what is just in itself, from what is merely accredited by an illustrious name; adopting a truth which no one has sanctioned, and rejecting an error of which all approve, with the same calmness as if no judgment were opposed to its own: but which, at the same time, alive with congenial feelings to every intellectual excellence, and candid to the weakness from which no excellence is wholly privileged, can dissent and confute without triumph, as it admires without envy; applauding gladly whatever is worthy of applause in a rival system, and venerating the very genius which it demonstrates to have erred.'

The second lecture is entitled Relation of the Philosophy of Mind to the Sciences; and the office of intellectual science is magnified with considerable effect; but there is nothing very worthy of being extracted, except the following sentence which contains the germe of the whole lecture, and which it is possible some minds require to have impressed upon them.

'To the philosophy of mind every speculation, in every science, may be said to have relation as to a common centre. The knowledge of any quality of matter, in the whole wide range of physics, is not itself a phenomenon of matter, more than the knowledge of any of our intellectual or moral affections; it is truly, in all its stages of conjecture, comparison, doubt, belief, a phenomenon of mind; or, in other words, it is only the mind itself existing in a certain state.'

The third lecture, entitled Influence of the Philosophy of Mind on the Understanding, points out, as is done in Locke's Essay, the importance of knowing the limits of our faculties, that we may attempt only possible knowledge and profitable enquiries; and the tendency of intellectual science to render us candid, tolerant, and liberal, towards those who differ from us in opinion, with its advantages to education, criticism, &c.

The fourth lecture, entitled Relation of the Philosophy of Mind to Morality, contains many good remarks, but nothing very new or remarkable.

The fifth and sixth lectures, Of Physical Enquiry, seem foreign to metaphysical discussion They contain, however, some important remarks such as the following:—'All physical science, whatever may be the variety of objects, mental or material, to which it is directed, is nothing more than the comparison of phenomena, and the discovery of their agreement or disagreement, or order of succession. It is on observation, therefore, or on consciousness, which is only another name for internal observation, that the whole of science is founded; because there can be no comparison without observation of the phenomena compared, and no discovery of agreement or disagreement without comparison. * * * What is it that we truly mean, when we say that we are about to enquire into the nature and properties of any substance? From the mere misunderstanding of this question, the brightest talents of a long succession of ages were wasted in enquiries as barren as the frivolous glory which attended them; that produced indeed much contention and more pride, but nothing more; and, without giving any additional knowledge, took away from ignorance only its humility, and its power of being instructed.'

The intention of these two lectures was to correct the scholastic notions, or rather to cancel the scholastic jargon about substance or matter; and though not very definite, lucid, or available for any important purpose, they are more successful than Locke's attempts of the same kind. 'Whenever the question is put as to any object, What is it? there are two and only two answers, that can be given with meaning. We may regard it as it exists in space, and state the elements that coexist in it, or rather that constitute it; or we may regard it as it exists in time, and state, in all the series of changes of which it forms an invariable part, the objects to which it is related as antecedent.' This is the text which the whole discussion labors to explain, illustrate, and establish.

The seventh lecture is on Power, Cause, and Effect, concerning which there has been so much said and written by men who frequently knew not what they said, or whereof they either affirmed, or denied, or disputed. Dr. Brown adopts, with a slight and unimportant difference, the statement of Hume, the latter resolving our belief as to the relation between cause and effect, or antecedent and consequent, into custom; the former into an original principle or tendency of our intellectual constitution. The doctrine of Hume was long regarded with horror by most theists as essentially atheistical; but it begins to be regarded as not only correct, but as having nothing necessarily atheistical about it; nay, it is now found or fancied by some of them to be one of the most powerful of all antidotes to atheism. 'If,' says Mr. Stewart, 'it be true, as Mr. Hume contends, and as most philosophers now admit, that physical causes and effects are known to us merely as antecedents and consequents, the whole system of Spinoza is nothing better than a rope of sand, and the very proposition which it professes to demonstrate is incomprehensible by our faculties. Mr. Hume's doctrine, in the unqualified form in which he states it, may lead to other consequences not less dangerous; but, if he had not the good fortune to lead metaphysicians

to the truth, he may at least be allowed the merit of having shut up for ever one of the most frequented and fatal paths which led them astray. It was, so far as I know, first shown in a satisfactory manner by Mr. Hume, that every demonstration which has been produced for the necessity of a cause to every new existence, is fallacious and sophistical. In illustration of this assertion, he examines three different arguments which have been alleged as proofs of the proposition in question; the first by Mr. Hobbes, the second by Dr. Clarke, and the third by Mr. Locke. And I think it will now be readily acknowledged, by every competent judge, that his objections to all these pretended demonstrations are conclusive and unanswerable.'

'To know the powers of nature,' says Dr. Brown, 'is nothing more than to know what antecedents are, and will be followed by what consequents; for this invariableness and not any distinct existence is all which the shorter term power, in any case expresses. By an original law or principle of our constitution, we are led from the mere observation of change to believe, that, when similar circumstances occur, the changes which we observe will also recur in the same order; there is hence conceived by us to be a permanent relation of one event, as invariably antecedent to another event, as invariably consequent; and that this permanent relation is all which constitutes power. It is a word, indeed, of much seeming mystery; but all which is supposed to be mysterious and perplexing in it vanishes, when it is regarded in its true light as only a short general term expressive of invariable antecedence; or, in other words, of that which cannot exist in certain circumstances, without being immediately followed by a certain definite effect, which we denominate an effect in reference to the antecedent, which we denominate a cause. To express, shortly, what appears to me to be the only intelligible meaning of the three most important words in physics, immediate, invariable, antecedent, is power; the immediate invariable antecedent, in any sequence, is a cause; the immediate invariable consequent is the correlative effect.'

We know not what other intelligible account can be given of the matter; nor do we perceive how it is possible for any thing necessarily atheistical to lurk in the statement; though we know that there are many good men of very respectable intellect, whom it would be difficult, if at all practicable, to convince that it is perfectly safe and sound. It would have been well if Dr. Brown had relied less on abstract and elaborate argumentation, and if he had proceeded more on the principle of confuting error, or of dispelling mental confusion by tracing it to its source in words; for such words as power, cause, effect, are mere relics of expressions or sentences, which were sufficiently explicit; but when reduced, abridged, or contracted, into what are called nouns, these relics of former expressions become the occasion of much error and metaphysical mystery and prejudice. Thus by substituting antecedent for cause, and consequent for effect, the work is in effect done on which so much elaborate argument has been expended, to prove, that is to bring men to admit, that there is nothing else and can be nothing else meant by them in using the word cause, but what is meant by antecedent. The word power is more difficult, because we happen to have no word that seems eligible or admissible as a substitute. In such a case it would be wise to throw away the apple of discord at once rather than eternally dispute about it. Dr. Brown virtually adopts what we consider the best method of ridding the world of metaphysical confusion and unprofitable controversy. 'That power,' he says, 'is nothing more than the relation of an object or event as antecedent to another object or event, its immediate and invariable consequent, may perhaps, from the influence of former habits of thought, or rather, of former abuse of language (or using it without any distinct meaning), at first appear to you an unwarrantable simplification. But the longer you attend to the notion, the more clearly will you perceive that all which you have ever understood in it, is the immediate sequence of some change with the certainty of the future recurrence of this effect as often as the antecedent itself may recur in similar circumstances. When a spark falls upon gunpowder, every one ascribes to the spark the power of kindling the inflammable mass. But let any one ask himself what he means by the term, and he will find nothing more than this, that in all similar circumstances the explosion of gunpowder will be the immediate and uniform consequence of the application of a spark.'

After the elaborate lecture on power, cause, and effect, there is nothing very worthy of notice till we come to the sixteenth lecture on the Classification of the Phenomena of Mind. In the intermediate ones there is abundance of things, or more properly, perhaps, nothings, treated of; but little that is said concerning them is very tangible, or very available. He tells us that 'analysis in the science of mind is founded wholly on the feeling of relation which one state of mind seems to us to bear to other states of mind as comprehensive of them;' that 'it has been strangely affirmed of the science of mind, that it is by its very nature insusceptible of improvement by discovery;' that 'there is indeed a chaos in the mind of man, but there is a spirit of enquiry for ever moving over it, slowly separating all its mingled elements; and it is only when these are separated that the philosophy of mind can be complete, and incapable of further discovery;' that 'mind is capable of existing in various states, an enumeration of the leading classes of which is all that constitutes our definition of it;' that 'the consideration of the mind, as one substance, capable of existing in a variety of states necessarily involves the consideration of consciousness and of personal identity;' that 'consciousness (which has a large tribute of lecture), is not, as Dr. Reid and his disciples maintain, a distinct power of the mind (and truly for the same reason that they make the obscure word consciousness into a power, they might create with the breath of their mouth a thousand powers or potentates in the mind, or rather in the nomenclature of their infallible, experimental, inductive

science), but only a general term for all our feelings of whatever species these may be—sensations, thoughts, desires; in short all those states or affections of mind in which its phenomena consist;' that 'conscience, which is not to be confounded with consciousness is moral memory, or the memory of the heart;' that 'the enquiry into the identity of the mind (he gives up personal identity in despair) as truly one and permanent amid all the variety of its fugitive affections, is a most important enquiry;' that 'the manner in which the mind is united to a system of particles, which are in a perpetual state of flux, is indeed more than we can ever hope to explain;' that 'our identity is the unity and sameness of that which thinks and feels; and the 'belief of our identity is intuitive and irresistible' (this, after a long, laboring, winding, slow process of reasoning, that would try the patience of Locke himself, is the result or sum total of discovery from the most important enquiry); that 'it is beyond our power to solve the question, how much the mere materialism of our language has operated in darkening our conceptions of the nature of the mind and of its various phenomena;' that 'it is a very egregious paradox of Locke in making personal identity consist in consciousness;' that 'it is a very shrewd remark of a French writer: if truth were fairly to show herself as she is, all would be ruined; but it is plain that she knows very well of how great importance it is that she should keep herself out of sight.' This is surely humbling enough to metaphysics—only to resign 'personal identity,' and to confess truth 'out of sight.'

The following are the most noticeable items of lectures sixteenth, seventeenth, and eighteenth, on the Classification of the Phenomena of Mind.

'The great leading division of the mental phenomena which has met with most general adoption by philosophers (and who besides ever troubled their heads about such outlandish entities as phenomena?), is into those which belong to the understanding, and those which belong to the will; a division which is very ancient, but though sanctioned by the approbation of many ages very illogical; since the will, which, in the division is nominally opposed to the intellect, is so far from being opposed to it in reality, that, even by the assertors of its diversity, it is considered as exercising in the intellectual department, an empire almost as wide as in the department allotted to itself. We reason, and plan, and invent, at least as voluntarily, as we esteem, or hate, or hope, or fear. How many emotions are there too which cannot, without absolute torture, be forced into either division. To take only a few instances out of many, to what class are we to reduce grief, joy, admiration, astonishment, which certainly are not phenomena of the mere understanding, and which, though they may lead indirectly to desires or volitions, have nothing in themselves that is voluntary, or that can be considered as in any peculiar degree connected with the will? The division of the mental phenomena into those which belong to the understanding, and those which belong to the will, seems, therefore, to be as faulty as would be the division of animals into those which have legs and those which have wings, since the same animals might have both legs and wings, and since all tribes of animals have neither one nor the other.'

That strain was of a higher mood! The lecturer is himself again! When he does not trifle among nullities and unideal abstractions, or attempt to go beyond the length of his line (as Mr. Stewart not very seemly or graciously remarks) he acquits himself nobly. Though he often fails in attempting to build up any thing new, as positive knowledge in the science of mind, he is always skilful, and dexterous, and mighty, in pulling down philosophic nonsense and absurdity. But let him proceed.

'Another division of the phenomena of mind, similar to the former, and of equal antiquity, since it corresponds with the very ancient division of philosophy into the contemplative and the active, is into those which belong to the intellectual powers, and those which belong to the active powers. This division of the mental phenomena as referrible to the intellectual and the active powers of the mind, though it has the sanction of very eminent names (as Dr. Reid and his disciples) is faulty exactly in the same manner as the former, which, indeed, it may be considered almost as representing under a change of name. Its parts are not opposed to each other, and it does not include all the phenomena which it should include. Is mere grief, for example, or mere astonishment, to be referred to our intellectual or to our active powers? I do not speak of the faculties which they may or may not call into action; but of the feelings themselves, as present phenomena or states of the mind. And, in whatever manner we may define the term active, is the mind more active when it merely desires good, and fears evil? when it looks with esteem on virtue, and with indignation or disgust and contempt on vice, than when it pursues a continued train of reasoning or fancy, or historical investigation? * * * So little, indeed, are the intellectual powers opposed to the active, that it is only when some intellectual energy co-exists with desire that the mind is said to be active, even by those who are unaccustomed to analytical enquiries, or to refinements of metaphysical nomenclature. The love of power, or the love of glory, where there is no opportunity of intellectual exertion, may, in the common acceptation of the word, be as passive as tranquillity itself. The passion is active only when, with intellectual action, it compares means with ends, and different means with each other, and deliberates, and resolves, and executes.' * * *

'If, then, as I cannot but think, the arrangement of the mental phenomena, as belonging to two classes of powers, the intellectual and the active, be at once incomplete and not accurate even to the extent to which it reaches, it may be worth while to try, at least, some other division, even though there should not be any very great hope of success. Though we should fail in our endeavour to obtain some more precise and comprehensive principle of arrangement, there is always some advantage gained by viewing objects according to new circumstances of agreement or analogy. We see, in this case, what

had long passed before us unobserved, while we were accustomed only to the order and nomenclature of a former method; for, when the mind has been habituated to certain classifications, it is apt in considering objects to give its attention only to those properties which are essential to the classification, and to overlook, or at least comparatively to neglect, other properties equally important and essential to the very nature of the separate substances that are classed, but not included in the system as characters of generic resemblance. * * * A new classification, therefore, which includes in its generic character those neglected qualities, will, of course, draw to them attention which they could not otherwise have obtained; and, the more various the views are which we take of the objects of any science, the juster consequently, because the more equal, will be the estimate which we form of them.'

We wish our space would permit us to extract more; the whole context is excellent. We must give one other quotation:—

'It may, perhaps, seem absurd, even to suppose, that we should think ourselves able to change, by a few generic words, the properties of the substances which we have classed; and if the question were put to us, as to this effect of our language in any particular case, there can be no doubt that we should answer in the negative, and express astonishment that such a question should have been put. But the illusion is not the less certain because we are not aware of its influence; and, indeed, it could no longer be an illusion, if we were completely aware of it. It requires, however, only a very little reflection on what has passed in our own minds, to discover that when we have given a name to any quality, that quality acquires immediately, in our imagination, a comparative importance, very different from what it had before; and, though nature in itself be truly unchanged, it is ever after, relative to our conception, different; a difference of words is, in this case, more than a verbal difference. Though it be not the expression of a difference of doctrine, it very speedily becomes so. Hence it is, that the same warfare which the rivalries of individual ambition, or the opposite interests, or supposed opposite interests of nations have produced in the great theatre of civil history, have been produced, in the small but tumultuous field of science by the supposed incompatibility of a few abstract terms; and, indeed, as has been truly said, the sects of philosophers have combated with more persevering violence to settle what they mean by the constitution of the world, than all the conquerors of the world have done to render themselves its masters. Let us now endeavour to form some better classification of the mental phenomena than has hitherto existed.

'Our states of mind, or our affections of mind, are the simplest terms which I can use to express the whole series of mental phenomena in all their diversity, without any mixture of hypothesis as to the particular mode in which the successive changes may be supposed to arise. When we consider these various states or affections of mind which form the series, one obvious circumstance of difference is, that some of them arise immediately, in consequence of the presence of external objects; and some as immediately in consequence of certain preceding states or affections (for the latter term is here used as exactly synonymous with the former) of the mind itself.

'There is then one obvious distinction of the mental phenomena in relation to their causes as external and internal. We shall therefore call the one class external states or affections of the mind, and we shall call the other internal states or affections, merely in reference to their immediate causes or antecedents. The former class (our external affections) is so simple as to require but little subdivision: the latter class (our internal affections or states of mind) comprehends so large a proportion of the mental phenomena, and these so various, that it requires subdivisions to enable us to derive any benefit from arrangement or classification.

'The first great subdivision of our internal affections which I would make is into our intellectual states and our emotions. The latter of these classes (our emotions) comprehends all or nearly all the mental states by others classed under the head of active powers, and commonly called affections and passions.

'We have sensations or perceptions of the objects around us that affect our bodily organs; these I term the sensitive or external affections of the mind: we remember objects—imagine them in new situations—we compare their relations; these mere conceptions or notions of objects, and their qualities as elements of our general knowledge, are what I term the intellectual states of the mind: we are moved with certain feelings on the consideration of what we thus perceive or remember, or imagine, or compare, with feelings for example to which we apply the terms beauty, sublimity, astonishment, love, hate, hope, fear &c.; these are what I mean by our emotions.

'There is no portion of our consciousness which does not appear to be included in one or other of these three divisions. To know all ou sensitive states or affections, all our intellectual states, and all our emotions, is to know all that we call the mental phenomena.

'It must not be supposed, however, that these different mental states, though as we conceive distinguishable, may not be combined or may not coexist at the same moment. They frequently concur, but in all cases in which they do concur or co-exist it is easy to distinguish them by reflective analysis.'

We have made some slight change of Brown's phraseology and verbal arrangement with the desire rather than the hope of simplifying, concentrating, and lucidising his statement; but perhaps we have rather marred than mended the matter. It would have been better probably either to have done more or nothing. And we think it possible to render the expression of even such abstract meaning more simple, clear, and definite, than has been accomplished by our author. Perhaps his general threefold classification may be all expressed by the three words sensation, intellection, and emotion; or in the plural, sensations, intellections, and emotions; which is after all very much the same as has been long in existence, answering to the senses, the intellects, and the

passions We think Dr. Brown's attempt is so far successful as to have some negative utility; it is at least calculated to rid the world of some absurd forms of speech and not a little foolish theory, and pretension, and parade, or, to use an ugly but forcible expression, philosophic humbug about the intellectual powers and faculties, which as arrayed by Reid, Stewart, and Kant, may be called legion, for they are many.

Whether Dr. Brown's statements have real worth, or be, after all their analytical acuteness, ingenuity, and dexterity, only like,

—The rhetorician's rules
Which serve him but to name his tools,

they are at least simplicity, and beauty, and reasonableness in perfection, when compared with the cumbrous, complex doctrines of Reid and Stewart. And notwithstanding all the sage counsels, and tart sarcasms, and indefatigable remonstrances on the subject, simplicity, all other things being equal (and it would be prudent perhaps for some of the lovers of complication to say less about depth and comprehension), is an eternal and immutable excellence.

O! how unlike the complex ways of man
Heaven's artless, easy, unincumbered plan!
—Like the cerulean arch you see
Majestic in its own simplicity.

He his fabric of the heavens
Hath left to their disputes, perhaps to move
His laughter at their quaint opinions wide,
Hereafter, when they come to model heaven
And calculate the stars, how they will wield
The mighty frame; how build, unbuild, contrive
To save appearances,—how gird the sphere,
With centric and eccentric scribbled o'er
Cycle and epicycle, orb in orb.

'As far as we have advanced,' says Dr. Brown, 'our division seems sufficiently distinct and comprehensive. The mind is susceptible of certain external affections, of certain intellectual modifications which arise from these, and of certain emotions which arise from both; that is to say it is capable of existing in certain states, the varieties of which correspond with these particular designations. We see, we remember, or compare what we have seen: we regard what we see, or remember, or compare, with desire or aversion; and of these, or of states analagous to these, the whole of life, sensitive, intellectual, or moral, is composed. Every minute, therefore, of every hour, in all its variety of occupation, is but a portion of this complicated tissue.'

This may be general, but it is extremely intelligible: it may be a theory, but it possesses a sort of internal evidence of genuineness, or that it is the true theory which almost irresistibly produces intuitive belief; for it is a perfect contrast to the old systems of the mind full of quaint device, and manifestly contrived to save appearances, and 'scribbled o'er,' with names and definitions as unintelligible as Egyptian hieroglyphics.

'You will remember,' repeats our author, 'that the various affections of which the mind is susceptible are either external, as they arise from causes without the mind, or internal, as they arise from previous states of the mind itself; that of these internal affections, some are mere conceptions or notions of former feelings, or of objects and of the qualities or relations of objects, as remembered or variously combined or compared,—results of different susceptibilities of our intellectual constitution, to which different names have been given, conception, memory, imagination, abstraction, reason, and other synonymous terms; that these internal affections or states of mind which I have denominated its intellectual states, are distinctly separable in our reflective analysis, from certain vivid feelings, that may arise instantly in the mind on the consideration of these mere intellectual results, or on the perception of objects without feelings of admiration, love, desire, and various other analogous or opposite states of the mind; but that there is such an order of vivid feelings, which arise, in many cases, on the mere consideration of what we perceive, or remember, or imagine, or compare: and that this order is what I wish to be distinguished by the name of emotion.

'According to this division of the mental phenomena, into those which are of external and those which are of internal origin, and the subdivision which we have made of this latter class, I shall proceed to consider, 1. The external powers or susceptibilities of the mind; 2. The intellectual powers or susceptibilities of the mind; and, 3. Its susceptibilities of emotion,—beginning with that class which we have every reason to suppose to be first, in the actual order of development, the powers or susceptibilities of the mind, in its immediate relation to its own bodily organs.'

Our limits will not permit us to attempt to follow Dr. Brown through his long, laboring, winding, and we think irksome discussion, concerning what he terms the external affections of the mind. It partakes too much of almost every kind of excellence, save simplicity, clearness, conclusiveness, and availableness. He is in short too acute, and subtile, and dexterously analytic in such matters to be always convincing or generally plausible. The mind is haunted with suspicions of the soundness of his statements at every step of his progress; and yet we think most of them possess more of probability than our understanding is disposed to allow from the over refined and untangible manner in which they are presented. Dr. Brown, however, in this part of his lectures is like Hartley, Locke, and almost all his metaphysical predecessors, too much infected with the old scholastic complaint of attempting impossible demonstration, and of adventuring with daring perversity on the forlorn hope of unprofitable speculation. He strives most mightily to go beyond the length of his tether, to adopt an allusion of his Herculean ancestor, which is certainly more remarkable for vernacular significance than for classical elegance. We think it almost more than probable that we learn or did learn the use of our senses in much the same manner as we learned the use of our hands and feet, and tongue, pronounced by the highest authority our glory; that it was by a gradual (though not so slow a) process that we became capable of seeing, and hearing, and feeling, and even tasting, and smelling, as well as of handling, and walking, and speaking. But what

then, how are we to arrive at demonstrative, inductive, experience, or intuitive certainty? And if we could arrive at infallible knowledge after much laborious toil and search after it, what the wiser, or better, or happier, should we be for the acquisition? It comes too late to be of any use, were it as sure and satisfactory, philosophically considered, as the Newtonian system of the universe. If we can find out by metaphysical research or analysis that our mental identity is to have the benefit of a second edition of this life, by being transmigrated into the body of an embryo or new-born infant, the lengthy and ingenious discussion of Dr. Brown may be of great practical utility as well as high speculative importance. In every other view we know not what benefit is to be derived from nearly the whole of Dr. Brown's seventeenth, eighteenth, nineteenth, twentieth, twenty-first, twenty-second twenty-third, and twenty-fourth lectures. They may indeed amuse some sorts of leisure minds, or fill up some empty space in college studies. However we shall endeavour to glean a few of the most noticeable or seemingly available remarks as specimens.

'In what circumstances the intuitive belief of an external world (if it be intuitive) arises, or rather in how large a proportion of cases, in which the reference seems primary and immediate, it is more probably the effect of secondary associations transferred from sense to sense, will appear better, on minute analysis of the different tribes of sensations.' 'The great essential organ of all sensations is the brain, with its appendages, particularly the nerves that issue from it to certain organs, which are more strictly termed the organs of sense; as it is there the immediate objects, or external causes of sensation, the particles of light, for example, in vision, or of odor in smell arrive, and come, as it were, into contact with the sensorial substance. The nervous matter has for its chief seat the great cavity of the head, but extends by innumerable ramifications over the whole surface, and through the internal parts of the body. Of the nature of the connexion of this great sensorial organ with the sentient mind we shall never be able to understand more than is involved in the simple fact, that a certain affection of the nervous system precedes immediately a certain affection of the mind.'

The conclusion intuitively arising from a thousand such remarks is that nothing can be concluded: Dr. Brown, with all his physiological and metaphysical ability, has left our senses and sensation just about where he found them; and he would have acted more judiciously perhaps if he had let them alone altogether. The twenty-fifth, twenty-sixth, twenty-seventh, and twenty-eighth lectures, are devoted to the confutation of Dr. Reid's supposed confutation of idealism; and, though Mr. Stewart had been indefatigably employed for almost half a century in building up the metaphysical claims of his master, Dr. Brown demolishes them in toto most triumphantly, convicting the Socrates of the Scottish metaphysic, or true philosophy of the human mind, of much 'zealous blundering;' which having been put confidently forth by himself, and clamorously applauded by his disciples, almost passed even beyond the borders for profound wisdom.

The twenty-ninth lecture is devoted to vision, which ought to have been disposed of among the other senses; but which, on account of its preeminent importance, was probably deemed worthy of standing alone and far apart, at least in discussion, from the less noble senses of hearing, tasting, smelling, and feeling. All Dr. Brown's remarks upon it are ingenious, and many carry in them much that is probable if not convincing.

'Vision,' says the lecturer, 'simple, and immediate, as it now seems to us, even in its most magnificent results, is truly the application of an art, of long and tedious acquirement, of that art with which we learn to measure forms and distances, with a single glance, by availing ourselves of the information previously received from other sources; the mixed product of innumerable observations, and calculations, and detections of former mistakes, which were the philosophy of our infancy, and each of which, separately, has been long forgotten, recurring to the mind, in after life, with the rapidity of an instinct.'

The thirtieth lecture is devoted to the history of opinions regarding perception, including those of the peripatetics, of Descartes, of Malebranche, of St. Austin, of Leibnitz. The discussion is chiefly interesting as exhibiting the error, prejudice, and folly, from which we have at last escaped. 'From all this variety of conjectural speculations (says the lecturer) the conclusion is, that which is too often the result of our researches in the history of science, that there may be, as D'Alembert truly says, a great deal of philosophising in which there is very little of philosophy.'

The external affections, as combined with desire and with attention, are considered in the thirty-first lecture; which however contains nothing very worthy of remark.

The thirty-second lecture treats of the classification of the internal affections; but contributes hardly any thing that can be regarded as information or instruction. The following remark is worth quoting:—'The philosophy of Dr. Reid and of the metaphysicians of this part of the island has enlarged far beyond what was necessary the number of classes of the mental phenomena, which they considered as too limited before. There can be no doubt that we are now accustomed to speak of more powers or operations of the mind, than even the schoolmen themselves, fond as they were of all the nicest subtilties of infinitesimal subdivisions.' According to Dr. Brown's statement, Condillac, the head of the French school of metaphysics, and Dr. Reid, the head of the Scottish school, may be regarded as metaphysical antipodes or opposite points, each in the extreme from the centre; Condillac erring by undue simplicity in representing all the mental states or operations as merely transformed sensation, as he terms them; and Dr. Reid erring on the opposite extreme of complexity, by multiplying unnecessarily intellectual powers and faculties. Condillac and Hartley may be regarded as homogeneous; and Reid and Kant, so far at least as multiplication of powers, faculties, and innate or instinctive principles are concerned.

In the thirty-third and subsequent lectures Dr. Brown proceeds with the internal states or affections; and we only regret the narrowness of our limits in reference to them; for they are exceedingly interesting. We shall try to accomplish multum in parvo.

'Our various states or affections of the mind I have already divided into two classes, according to the nature of the circumstances which precede them,—the external and the internal; and this latter class into two orders,—our intellectual states of mind, and our emotions. It is with the intellectual states or phenomena that we are at present concerned; and this order I would arrange under the generic capacities, that appear to comprehend in them all the phenomena of the order. The whole order, as composed of feelings, which arise immediately, in consequence of certain former feelings of the mind, may be technically termed, in reference to these feelings which have induced them, suggestions, but in the suggested feelings themselves there is one striking difference. If we analyse our trains of thought, exclusively of the emotions which may coexist or mingle with them, and of sensations that may be accidentally excited by external objects, we shall find them to be composed of two very distinct sets of feelings, one set of which are mere conceptions or images of the past, that rise, image after image in regular sequence, but simply in succession, without any feeling of relation necessarily involved, while the perception of relation, in the various objects of our thoughts, form another set of feelings, of course as various as the relations perceived,—perceptions and relations; it is with these, and with these alone, that we are intellectually conversant. There is thus an evident ground for the arrangement of the internal suggestions, that form our trains of thought, under two heads, according as the feeling excited directly by some former feeling may be either a simple conception, in its turn, perhaps, giving place to some other conception as transient; or may be the feeling of a relation which two or more objects of our thoughts are considered by us as bearing to each other. There is in short, in the mind, a capacity of association; or as, for reasons afterwards to be stated, I would rather term it,—the capacity of simple suggestion, by which feelings, formerly existing, are revived in consequence of the mere existence of other feelings, as there is also a capacity of feeling, resemblance, difference, proportion, or relation in general, when two or more external objects, or two or more feelings of the mind itself, are considered by us; which mental capacity, in distinction from the former, I would term the capacity of relative suggestion; and of these simple and relative suggestions, our whole intellectual trains of thought are composed.

'The intellectual states of the mind, then, to give a brief illustration of my division, I consider as all referrible to two generic susceptibilities, those of simple suggestion and relative suggestion. Our perception or conception of one object excites of itself, and without any known cause external to the mind, the conception of some other object; as when the mere sound of our friend's name suggests to us the conception of our friend himself, in which case the conception of our friend, which follows the perception of the sound, involves no feeling of any common property with the sound which excites it, but is precisely the same state of mind which might have been induced by various other previous circumstances; by the sight of the chair on which he sat, of the book which he read to us, of the landscape which he painted. This is simple suggestion.

'But, together with this capacity of simple suggestion, by which conception after conception arises precisely in the same manner, and in the same state, as each might have formed a part of other trains, and in which the particular state of mind that arises by suggestion does not necessarily involve any consideration of the state of mind which preceded it; there is a suggestion of a very different sort, which in every case involves the consideration not of one phenomenon of mind, but of two or more phenomena, and which constitutes the feeling of agreement, disagreement, or relation of some sort. I perceive, for example, a horse and a sheep at the same moment. The perception of the two is followed by that different state of mind which constitutes the feeling of their agreement in certain respects, or of their disagreement in certain other respects. I think of the square of the hypothenuse of a right-angled triangle, and the squares of the two other sides;—I feel the relation of equality; I see a dramatic representation; I listen to the cold conceits which the author of the tragedy, in his omnipotent command over warriors and lovers of his own creation, gives to his hero, in his most impassioned situations; I am instantly struck with their unsuitableness to the character and the circumstances. All the intellectual successions of feelings in these cases, which constitute the perception of relation, differ from the result of simple suggestion in necessarily involving the consideration of two or more objects, or affections of mind, that immediately preceded them. I may think of my friend in the case of simple suggestions; that is to say, my mind may exist in the state which constitutes the conception of my friend without that previous state which constitutes the perception of the sound of his name; for the conception of him may be suggested by various objects and remembrances. But I cannot, in the cases of relative suggestion, think of the resemblance of a horse and a sheep; of the proportion of the squares of the sides of a right-angled triangle; or of the want of the truth of nature in the expressions of a dramatic hero, without those previous states of mind which constitute the conceptions of a horse and a sheep, of the sides of the triangle, or the language of the warrior or lover, and the circumstances of triumph, or hope, or despair, in which he is exhibited to us by the creative artist.

'With these two capacities of suggested feelings simple and relative, which are all that truly belong to the class of intellectual states of the mind, various emotions may concur, particularly that most general of all emotions, the emotion of desire in some one or other of its various forms. According as this desire does or does not concur with them, the intellectual states themselves ap-

pear to be different; and, by those who do not make the necessary analysis, are supposed therefore to be indicative of different powers. By simple suggestion, the images of things, persons, events, pass in strange and rapid succession; and a variety of names, expressive of different powers, conception, association, memory, have been given to this one simple law of our intellectual nature. But when we wish to remember some object; that is to say, when we wish our mind to be affected in that particular manner which constitutes the conception of a particular thing, or person, or event, or when we wish to combine new images, in some picture of fancy, this coexistence of desire with the simple course of suggestion, which continues still to follow its own laws, as much as when no desire existed with it, seems to us to render the suggestion itself different; and recollection, and imagination, or fancy, which are truly, as we shall afterwards find, nothing more than the union of the suggested conceptions, with certain specific permanent desires, are to us, as it were, distinct additional powers of our mind, and are so arranged in the systems of philosophers, who have not made the very simple analyses, which alone seem to me to be necessary for a more precise arrangement.

'In like manner those suggestions of another class, which constitute our notions of proportion, resemblance, difference, and all the variety of relations, may, as already remarked, arise, when we have had no previous desire of tracing the relations, or may arise after that previous desire. But, when the feelings of relation seem to us to arise spontaneously, they are not in themselves different from the feelings of relation that arise, in our intentional comparisons or judgments, in the longest series of ratiocination. Of ratiocination they are truly the most important elements. The permanent desire of discovering something unknown, or of establishing or confuting or illustrating some point of belief or conjecture, may coexist, indeed, with the continued series of relations that are felt, but does not alter the nature of that law by which these judgments or relative suggestions succeed each other. There is no new power to be found, but only the union of certain intellectual states of the mind, with certain desires, a species of combination not more wonderful in itself than any other complex mental state, as when we at the same moment see and smell a rose, or listen to the voice of a friend who has been long absent from us, and see at the same moment that face of affection which is again giving confidence to our heart and gladness to our very eyes.

'Our intellectual states of mind, then, are either those resemblances of past affections of the mind which arise by simple suggestion, or those feelings of relation which arise by what I have termed relative suggestions,—the one set resulting, indeed, from some prior states of the mind, but not involving, necessarily, any consideration of these previous states of mind, which suggested them; the other set necessarily involving the consideration of two or more objects, or two or more affections of the mind, as subjects of the relation which is felt.

'How readily all the intellectual states of mind, which are commonly ascribed to a variety of powers, may be reduced to those two, will appear more clearly after we have considered and illustrated the phenomena of each set.'

Dr. Brown proceeds to treat, first, of simple, and, secondly, of relative suggestion; and the discussion, which is one of the most important in the whole course, extends from the beginning of the thirty-fourth to the end of the forty-seventh lecture. We shall endeavour to shorten and simplify his statements, or rather to extract their essential excellence.

Simple Suggestion.—The term suggestion, as substituted for Locke's unhappy expression, association of ideas, seems to have been adopted from Berkeley, who had used it in much the same sense, or for much the same purpose. The following reasons are assigned for its preference and adoption. The limitation of the term association, to those states of mind exclusively denominated ideas, has tended greatly to obscure the subject, or at least to deprive us of the aid which might have been received from it in the analysis of the most complex phenomena. The influence of the associating principle extends not to ideas only, but to every species of affection of which the mind is susceptible. Joys, sorrows, and all the variety of emotions, are capable of being revived, in a certain degree, by the mere influence of this principle, and of blending with the ideas, or other feelings which awakened them, in the same manner as our conceptions of external things. These last, however, it must be admitted, present the most striking and obvious examples of the influence of the principle, and are therefore the fittest for illustrating it, as well as most calculated to arrest attention. The faint and shadowy elements of past emotions, as mingling in any present feeling, it may not be easy to distinguish; but our remembrances of things without are clear and definite, and are easily recognised as images of the past.

That, when two objects have been perceived in immediate succession or co-existence, the presence of the one will often suggest or call up the other (though that other, or a similar external cause, be not present), is that great fact of association or suggestion which we must admit, whatever opinion we may form with respect to its nature, or whatever name we may give to it. But is this fact to be resolved into a general tendency of the mind first operating at the moment of the suggestion itself, or to an earlier tendency, or principle, or law? The latter supposition would probably never have existed, but for the introduction of the ambiguous and inappropriate term association. It is the use of this unfortunate phrase (when a term so much simpler as suggestion might have been employed) which appears to have filled our intellectual systems with the names of so many superfluous powers. The supposed necessity, in our trains of thought, of some previous association, of course rendered it necessary that the conceptions ascribed to this cause should be such as before existed in a similar form, since, without this previous existence, they could not be supposed to admit of previous connexion; and, therefore,

when the suggestions were so very different, as to have the semblance almost of a new creation, it became necessary to invent some new power, distinct from that of association, to which they might be ascribed. What was in truth a mere simple suggestion, flowing from the same laws with other suggestions, became in this manner something more, and was ranked as a product of fancy, or imagination; nothing being so easy as the invention of a new name. A similar allusion gave rise to the supposition of various other intellectual powers, or at least favored greatly the admission of such powers, by the difficulty of accounting for suggestions, which could not have arisen from previous associations; and one simple power or susceptibility of the mind was thus metamorphosed into various powers, all distinct from each other, and distinct from that power of which they were only modifications.

That there is a tendency of ideas to suggest each other, without any renewed perception of the external objects which originally excited them, and that the suggestion is not altogether loose and indefinite, but that certain ideas have a peculiar tendency to suggest certain other relative ideas, in associate trains or bands of thought, is too familiar, as a general fact of our intellectual nature, to require to be illustrated by example. It is beautifully expressed by one of our most philosophic poets, Akenside:—

When the different images of things,
By chance combined, have struck the attentive soul
With deeper impulse, or, connected long,
Have drawn her frequent eye; howe'er distinct
The external scenes, yet oft the ideas gain
From that conjunction an eternal tie,
And sympathy unbroken. Let the mind
Recal one partner of the various league,
Immediate, lo! the firm confederates rise,
And each its former station straight resumes;
One movement governs the consenting throng,
And all at once with rosy pleasure shine,
Or all are saddened with the glooms of care.
* * * * * * * *
Such is the secret union, when we feel
A song, a flower, a name, at once restore
Those long connected scenes when first they moved
The attention. Backward, through her mazy walks,
Guiding the wanton fancy to her scope,
To temples, courts, or fields—with all the band
Of living forms, of passions, and designs
Attendant; whence, if pleasing in itself,
The prospect from that sweet accession gains
Redoubled influence o'er the listening mind;
By these mysterious ties, the busy power
Of memory her ideal train preserves
Entire; or, when they would elude her watch,
Reclaims their fleeting footsteps from the waste
Of dark oblivion.

What then are these mysterious ties?—or, to state the question more philosophically, what are the general circumstances which regulate the successions of ideas? That there is some regularity in these successions must have been felt by every one; and there are many references to such regularity in the works of philosophers of every age. The most striking ancient reference, however, to any general circumstances, or, as usually called, laws of suggestion (though the enumeration is rather hinted than developed), is that quoted by Dr. Beattie and Mr. Stewart from Aristotle. It is a passage explanatory of the process by which, in voluntary reminiscence, we endeavour to discover the idea of which we are in search. We are said to hunt for it (*θηρεύομεν*) among other ideas, either of objects existing at present, or at some former time; and from their resemblance, contrariety, and contiguity, *ἀπο τῦ νῦν, ἢ ἄλλυ τινὸς καὶ ἀφ' ὁμοίυ, ἢ ἐναντίυ ἢ τοῦ συνέγγυς. Διὰ τῦτο γινεταὶ ἡ αναμνησις.*

This brief enumeration of the general circumstances which direct us in reminiscence merits attention on its own account, and also on account of the very close resemblance it bears to the statement of Hobbes, and to the arrangement afterwards made by Hume. As Dr. Brown has intentionally, or unintentionally, omitted all mention of Hobbes in this connexion, we shall quote his words at some length. 'By consequence, or train of thoughts (Leviathan, part I. chap. iii., Of the Consequence or Train of Imaginations), I understand the succession of one thought to another, which is called, to distinguish it from discourse in words, mental discourse. When a man thinks on any thing whatsoever, his next thought after it is not altogether so casual as it seems to be. Not every thought to every thought succeeds indifferently. But as we have no imagination whereof we have not formerly had sense, or sensation, in whole, or in part; so we have no transition from one imagination to another, whereof we have never had the like before in our senses. The reason of which is this: all fancies are motions within us, relics of those made in the sense: and those motions that immediately succeed one another in the sense continue also together after sense: insomuch as the former coming again to take place, and to be predominant, the latter follows, by coherence of the matter moved, in such manner as water upon a plane table is drawn which way any one part of it is guided by the finger. But because in sense sometimes one thing, sometimes another, succeedeth, it comes to pass in time, that, in the imagination of any thing, there is no certainty what we shall imagine next: only this is certain, it shall be something that succeeded the same before, at one time or another.

This train of thoughts, or mental discourse, is of two sorts. The first is unguided, without design, and inconstant; wherein there is no passionate thought, to govern and direct those that follow, to itself, as the end and scope of some desire, or other passion: in which case the thoughts are said to wander, and seem impertinent one to another, as in a dream. Such are commonly the thoughts of men, that are not only without company, but also without care of any thing; though even then their thoughts are as busy as at other times, but without harmony; as the sound which a lute out of tune would yield to any man; or, in tune, to one that could not play. And yet, in this wild ranging of the mind, a man may ofttimes perceive the way of it, and the dependence of one thought upon another. For, in a discourse of our present civil war what could seem more impertinent than to ask, as one did, what was the value of a Roman penny? Yet the coherence to me was manifest

enough. For the thought of the war introduced the thought of the delivering up the king to his enemies; the thought of that, brought in the thought of the delivering up of Christ; and that again the thought of the thirty pence, which was the price of that treason; and hence easily followed that malicious question; and all this in a moment of time, for thought is quick.

'The second is more constant; as being regulated by some desire and design. For the impression made by such things as we desire or fear is strong and permanent, or, if it cease for a time, of quick return: so strong it is sometimes, as to hinder and break our sleep. From desire arises the thought of some means we have seen produce the like of that which we aim at; and, from the thought of that, the thought of means to that mean; and so continually, till we come to some beginning within our own power. And because the end, by the greatness of the impression, comes often to mind, in case our thoughts begin to wander, they are quickly again reduced into the way; which, observed by one of the seven wise men, made him give men this precept, which is now worn out, respice finem; that is to say, in all your actions, look often upon what you would have, as the thing that directs all your thoughts in the way to attain it.

'The train of regulated thoughts is of two kinds; one, when of an effect imagined we seek the causes, or means that produce it; and this is common to man and beast. The other is, when, imagining any thing whatsoever, we seek all the possible effects that can by it be produced; that is to say, we imagine what we can do with it when we have it. Of which I have not seen any sign but in man only; for this is a curiosity hardly incident to the nature of any living creature that has no other passion but sensual, such as hunger, thirst, lust, and anger. In sum, the discourse of the mind, when governed by design, is nothing but seeking, or the faculty of invention, which the Latins call sagacitas and solertia; a hunting out of the causes of some effect, present or past; or of the effects of some present or past cause. Sometimes a man seeks what he has lost; and, from that time and place wherein he misses it, his mind runs back from place to place, and time to time, to find where and when he had it; that is to say, to find some certain and limited time and place in which to begin a method of seeking. Again, from thence, his thoughts run over the same places and times, to find what action, or other occasion, might make him lose it. This we call remembrance, or calling to mind; the Latins call it reminiscentia, as it were a re-conning of our former actions.

'Sometimes a man knows a place determinate, within the compass of which he is to seek; and then his thoughts run over all the parts thereof, in the same manner as one would sweep a room to find a jewel; or as a spaniel ranges the field till he find a scent; or as a man should run over the alphabet to start a rhyme [or find the name of a person, a place, a thing].

'Sometimes a man desires to know the event of an action; and then he thinketh of some like action past, and the events thereof, one after another; supposing like events will follow like actions. As he that foresees what will become of a criminal, re-cons what he has seen follow on the like crime before; having this order of thought, the crime, the officer, the prison, the judge, and the gallows. Which kind of thought is called foresight, and prudence, or providence; and sometimes wisdom; though such conjecture, through the difficulty of observing all circumstances, is very fallacious. But this is certain, by how much one man has more experience of things past than another, by so much also he is more prudent, and his expectations the seldomer fail him. The present only has a being in nature; things past have a being in the memory only; but things to come have no being at all; the future being but a fiction of the mind, applying the sequels of actions past to the actions which are present; which, with most certainty, is done by him that has most experience; but not with certainty enough. And though it be called prudence, when the event answereth our expectation, yet, in its own nature, it is but presumption. For the foresight of things to come, which is providence, belongs only to him by whose will they are to come. From him only, and supernaturally, proceeds prophecy. The best prophet, naturally, is the best guesser; and the best guesser, he that is most versed and studied in the matters he guesses; for he has most signs to guess by.'

We have quoted more than was absolutely to our purpose, the better to enable the reader to compare the thoughts, and manner of thought and expression, in Hobbes, with those of Brown and Hume.

'Though it be too obvious,' says Hume, 'to escape observation, that different ideas are connected together, I do not find that any philosopher has attempted to enumerate or class all the principles of association; a subject however that seems worthy of curiosity. To me there appear to be only three principles of connexion among ideas, viz. resemblance, contiguity in time or place, and cause or effect.

'That these principles serve to connect ideas will not, I believe, be much doubted. A picture naturally leads our thoughts to the original. The mention of one apartment naturally introduces an enquiry concerning the others. And if we think of a wound we can scarcely forbear reflecting on the pain which follows it. But that the enumeration is complete, and that there are no other principles of association except these, may be difficult to prove to the satisfaction of the reader, or even to a man's own satisfaction. All we can do, in such cases, is to run over several instances, and examine carefully the principle which bends the different thoughts to each other, never stopping till we render the principle as general as possible. The more instances we examine, and the more care we employ, the more assurance shall we acquire that the enumeration which we form from the whole is complete and entire.' — *Enquiry concerning Human Understanding*, Sect. III.

On this enumeration of Mr. Hume Dr. Brown justly remarks:—'Causation, so far from being opposed to contiguity, so as to form a separate

class, is, in truth, the most exquisite species of proximity in time, and in most cases of contiguity in place also, which could be adduced; because it is not a proximity depending on casual circumstances, and consequently liable to be broken, but one which depends solely on the mere existence of the two objects that are related to each other as cause and effect, and therefore fixed and never-failing. On his own principles, therefore, the three connexions of our ideas should indisputably be reduced to two. To speak of resemblance, contiguity, and causation, as three distinct classes, is, with Mr. Hume's view of causation, and indeed with every view of it, as if a mathematician should divide lines into straight, curved, and circular.

But are these truly distinct classes of suggestion that are not reducible to any more common principles? or are they not all reducible to a single influence? All suggestions may, by minute analysis, be found to depend on prior co-existence.

For this reduction, however, we must take in the influence of emotions, and other feelings, very different from ideas; as when an analogous object suggests an analogous object by the influence of an emotion or sentiment, which each separately may have produced before, and which is therefore common to both. But, though a minute analysis may bring all our suggestions to one common influence of former proximity or co-existence of feelings, it is very convenient in illustration of the principle to avail ourselves of the most striking subdivisions, in which the particular instances of that proximity may be arranged; and, by substituting contrast for the superfluous subdivision of causation, the enumeration will stand thus:—1. Resemblance, including every species of analogy. 2. Contrast. 3. Contiguity.

The obvious instances of the effect of strong similarity in recalling objects are innumerable. Those which produce impressions on the organs of sense, and through them directly on the mind, do not require any indication. There is another species of resemblance founded on more shadowy analogies which gives rise to an innumerable series of suggestions. To these we owe the simile, the metaphor, and figurative language in general. In poetry we perceive every where what Akenside calls

> The charm
> That searchless nature o'er the sense of man
> Diffuses—to behold, in lifeless things,
> The inexpressive semblance of himself,
> Of thought and passion.

The zephyrs laugh—the sky smiles—the forest frowns—the storm and the surge contend together—the solitary place not merely blossoms like the rose, but is glad: all nature becomes animated. It is the metaphor which forms the essence of the language of poetry; and it is to a peculiar mode of the associating principle that the metaphor owes its birth, whether the analogy be derived from the moral to the physical, or from the physical to the moral world. The metaphor expresses with rapidity the analogy as it rises in immediate suggestion, and identifies it with the object of emotion which it describes; the simile presents, not the analogy merely, but the two analogous objects, and traces their resemblance with the formality of regular comparison. The metaphor is the figure of passion; the simile is the figure of calm description.

There is another set of resemblances, not in the objects themselves but in the mere verbal signs which indicate them, which have a powerful though less obvious influence on suggestion, and, without appearing to have any agency, often guide the trains of our thought and emotion. Our thoughts, which usually govern our language, are themselves, in a great measure, governed by that very language over which they seem to exercise unlimited sway; so true, in more respects than one, is the memorable and often quoted observation of Bacon, 'Credunt homines rationem suam verbis imperare, sed fit etiam ut verba vim suam super rationem retorqueant.' We do not speak at present of the influence which was particularly contemplated by the remark of that great master of wisdom in detecting the sources of error and prejudice; but of the influence which language indirectly acquires as a series of sounds, suggesting each other by their own similarity. Similar sounds suggest, by their mere similarity, similar sounds; and the words thus suggested awaken the conceptions which they are accustomed to express, and consequently the whole train of thoughts and images associated with these conceptions, which would not have arisen but for the accidental resemblance of one symbol to another.

Hence the influence of puns, rhymes, alliteration, &c. It is only where the direct verbal suggestion is rendered more apparent by the strange incongruity of the images, which the similar sounds chance to denote, as in the case of puns, that we usually ascribe the suggestion to the word and not to the thought itself. Even in the case of puns, it is only to the few in which the contrast of meaning is very striking that we pay any attention. How many words of similar sound arise in the mind, by this species of suggestion, which are never uttered as puns but pass silently away, because they are felt to be without that lucky ambiguity or opposition of meaning which alone could reconcile the hearers to this petty species of wit, or feed the vanity of the weakest mind so as to make it glory in so contemptible a kind of success and triumph? Next to this petty species of wit, as a proof of the influence of mere verbal similarities of sound in suggestion, the connecting influence of rhyme is obvious. That in rhyme sound suggests sound, and consequently operates indirectly on the train of thought by the mere symbolic resemblance, there can be no question, since it is nothing but the recurrence of similar sounds at regular or irregular intervals; and to these recurring sounds the train of thought must be, in a considerable degree, subservient, however great its independence may seem. Butler wittily compares rhyme to the rudder, which, though in the rear of the vessel, and apparently following its direction, directs the track which the whole vessel itself is to pursue. An influence on the succession or direction of thought, similar to that of the concluding syllables of verse, is exercised by the initial sounds

of words in alliteration. How readily suggestions of this kind occur, so as to modify indirectly the train of images and feelings in the mind, and what pleasure they afford when they seem to have arisen without effort, is marked by the tendency to alliteration which is so prevalent, not in the poetry merely, but still more in the traditionary proverbs of every country; as also in the alliterative designation of the heroes of romance. It is in verse, however, that the charm of alliteration is most powerfully felt. The following are obvious examples.

> Fill but his purse our poet's work is done,
> Alike to him by pathos or by pun.

> Or her whose life the church and scandal share
> For ever in a passion or a prayer.

The alliteration of words that express opposite ideas is a species of wit, as far as the pleasure of wit consists in the sudden discovery of unexpected resemblances, and approaches very nearly the nature of a pun, combined at the same time with the ludicrous antithesis which the objects themselves would have produced even without alliteration. Whether the resemblance be in the whole word, as in the pun, or only in part of the word, as in alliteration, the suggestion may be considered a decisive proof of the influence which is exercised over our trains of thought by the mere accident of the agreement of arbitrary sounds.

The force of contrast, as a suggesting principle, is next to be considered. Of this influence the instances are innumerable. The palace and the cottage—the cradle and the grave—the extremes of indigence and of luxurious splendor are not connected in artificial antithesis only, but arise in ready succession to the observing or reflecting mind without even the intervention of words, or any intention of producing effect upon any other mind. The mind of its own spontaneous accord is often not only busy comparing, but contrasting the objects of its perception. It is this tendency of the mind to pass readily from opposites to opposites, which renders the antithesis natural. When skilfully and sparingly used, it is unquestionably a figure of great power, from the impression of astonishment which the rapid succession of contrasted objects must always produce. This very facility, however, of producing astonishment at little cost of real eloquence, renders the antithesis the most dangerous and seductive of all the dangerous and seductive figures to a young orator.

We proceed to the consideration of nearness in time or place, the next general circumstance which has been specified as modifying suggestion. Of all the general principles of connexion in the mental trains, this is evidently the most frequent and extensive in its operation. Contiguity, or obvious nearness, in time or place, forms the whole calendar of the great multitude of mankind, who pay little attention to the arbitrary eras of chronology, but date events by each other, and speak of what happened in the time, or before, or after, some persecution, or rebellion, or great war, or frost, or famine. It is the same with nearness in place. To think of one part of a familiar landscape is to recal the whole. The hill, the grove, the church, the river, the bridge, and all the walks which lead to them, rise before the mind in immediate succession. From neighbouring place to place the thoughts wander readily with a sort of untaught geography; and but for this connecting principle, not even the labor of the longest life could have fixed in our mind the simple knowledge of that intuitive science.

It may be proper to enquire into the circumstances which modify the suggesting principle, or what may be termed its primary laws (in conformity to custom, though the expression is somewhat objectionable, being calculated rather to obscure and mislead than to enlighten and guide the understanding), resemblance, contrast, and contiguity. What are the modifying circumstances which (though not very happily) may be termed secondary laws? They seem evidently the following:—

1. That which induces one associate conception rather than another, is the length of time during which the original feelings (from which the associated conception arose) co-existed with, or succeeded each other. Objects slightly observed make no deep and lasting impression or permanent associations in the mind. The longer we dwell on objects the more fully do we rely on our future remembrance, which is a particular determination or exercise of mental suggestion. This is so obvious, indeed, as to be in a manner truistical.

2. The parts of a train appear to be more closely and firmly associated as the original feelings have been more lively. We remember brilliant objects more than those which are faint or obscure. Occasions of great joy or sorrow, pleasure or pain, rapture or perturbation, are seldom wholly forgotten; slight pleasures and pains, &c., which occur every hour, pass away like time itself, never to return. That strong feeling of interest and curiosity which we call attention, not only fixes the mind in longer contemplation of certain objects, but gives them more of vividness to our perception. Emotion then has powerful influence on the mental suggestion; and the more powerful the emotion, the more of a particular determination is given to the suggesting principle.

3. The parts of any train are more readily suggested in proportion as they have been more frequently renewed. Thus we remember verses after three or four readings which we could not have remembered after one reading. This also is so obvious as to be almost truistical.

4. Feelings are connected more strongly in proportion as they are more or less recent. Immediately after reading any single line of poetry we are able to repeat it, though we may have given it no particular attention; in a few minutes or hours after, we are no longer able to repeat it accurately. There is a striking exception to this in the case of old age; for events of youth are remembered when those of the year or perhaps week preceding are forgotten. Yet even in the case of extreme old age the same holds when the time is not so far back; and events which happened a few hours before are remembered, when those of as many days of priority are forgotten.

5. Successive feelings are associated more closely and permanently in proportion as they have co-existed more exclusively, or in a state of greater separation from other feelings. The song which we have never heard but from one person, or in one place, or in a particular state of mind, can scarcely be heard again by us without recalling that with which it was solely, so to speak, identified; but there is obviously much less chance of any such particular suggestion if we have heard the same air and words frequently sung by different persons, in different places, or in great variety of mental states as to cheerfulness or sadness, joy or grief, pleasure or pain.

6. The influence of the suggesting principle or tendency in consequence of (what may in compliance with custom be called the primary laws of suggestion) resemblance, contrast, and contiguity, is greatly modified by original constitutional differences, whether these are to be referred to the mind itself, or to varieties of bodily temperament. Such constitutional differences affect the suggesting tendencies in two ways; first by augmenting and extending the influence of all of them, as in the varieties of the general power of remembering so observable in different individuals; secondly they modify that influence by giving greater proportional vigor to one set of tendencies than to another. It is in this modification of the suggesting principle, and the peculiar suggestions to which it gives rise, that the chief part or rather the whole of what is properly termed genius seems to consist. We have seen that the primary tendencies of suggestion are of various species, some for example arising from mere analogy, others from direct contiguity, or nearness in time or place of the very objects themselves: and it is this difference of the prevailing tendency, as to these two species of suggestion, which appears to constitute all that is inventive in genius; invention consisting in the suggestions of analogy, as opposed to the suggestions of grosser contiguity.

This is by far the most interesting statement of all in reference to suggestion; but we have not been able to master and manage it to our satisfaction so as to free it from all obscurity and embarrassment, or to render it concise, simple, clear, and definite. What Dr. Brown means by saying 'constitutional differences affect the primary laws, first by augmenting and extending the influence of all of them, as in the varieties of the general power of remembering, so observable in different individuals,'—or how if it be intelligible, and understood as we suppose it must be understood, it can be consistent with other parts of his statements, we are at a loss to divine. We think by leaving the clause out altogether, the whole of the other part would be correct. What he says concerning genius is so admirable (for it is almost the only thing at all like a successful attempt of the kind), that we must give it at some length.

In the mind of one poet, for example, the conception of his subject awakens only such images as he had previously seen combined with it in the works of others; and he is thus fated, by his narrow and unvarying range of suggestion, only to add another name to the eternal list of imitators. In a poetic mind of a higher order the conception of this very subject cannot exist for a moment without awakening, by the different tendency of the suggesting principle, groups of images which never before had existed in similar combination; and, instead of being an imitator, he becomes a great model for the imitation of others. The prevailing suggestions of the one, in his trains of thought, are according to the relation of analogy, which is almost infinite; the prevailing suggestions of the other are those of contiguity of the images themselves, which, by its very nature, admits of no novelty, and gives only transcripts of the parts. To tame down original genius, therefore, to mere imitation, and to raise the imitator to some rank of genius, it would be necessary only to reverse these simple tendencies. The fancy of the one would then, in the suggestions of mere contiguity, lose all that variety which had distinguished it, and would present only such combinations of images as had before occurred to it in similar order, in the works of former writers; the fancy of the other, on acquiring the peculiar tendency to suggestions of analogy, would become instantly creative, new forms of external beauty or of internal passion would crowd upon his mind, by their analogy to ideas and feelings previously existing, and this single change of the direction of the suggesting principle would be sufficient to produce all those wonders which the poet of imagination ascribes to the influence of inspiring genii,

> Who conduct the wandering footsteps of the youthful bard,
> New to their springs and shades; who touch his ear
> With finer sounds; who heighten to his eye
> The bloom of nature; and before him turn
> The gayest, happiest attitudes of things.

The inventions of poetic genius, then, are the suggestions of analogy: the prevailing suggestions of common minds are those of mere contiguity; and it is this difference of the occasions of suggestions, not of the images suggested, which forms the distinctive superiority of original genius. Copious reading and a retentive memory may give to an individual, of very humble talent, a greater profusion of splendid images than existed in any one of the individual minds, on whose sublime conceptions he has dwelt till they have become, in one sense of the word, his own. There is scarcely an object which he perceives that may not now bring instantly before him the brightest imagery; but, for this suggestion, however instant and copious, previous co-existence or succession of the images was necessary; and it is his memory, therefore, which we praise. If half the conceptions which are stored in his mind, and which rise in it now in its trains of thought by simple suggestion, as readily as they arose in like manner in accordance with some train of thought in the mind of their original authors, had but risen by the suggestion of analogy, as they now arise by the suggestion of former proximity, what we call memory, which is, in truth, only the same suggestion in different circumstances, would have been fancy or genius; and his country and age would

have another name to transmit to the reverence and the emulation of the ages that are to follow.

It is the same with inventive genius in the sciences and the severer arts; which does not depend on the mere knowledge of all the phenomena previously observed, or of all the applications of them that have been made to purposes of art, but chiefly on the peculiar tendency of the mind to suggest certain analogous ideas in successions, different from those ordinary successions of grosser contiguity which occur to common minds. He may, perhaps, be called a philosopher, who knows accurately what others know, and produces with the same means which others employ the same effects which they produce. But he alone has philosophic genius, to whose speculations analogous effects proceed from analogous causes, and who contrives practically by the suggestion of analogy to produce new effects, or to produce the same effects by new and simpler means.

7. Differences of temporary emotion also (as well as constitutional differences) influence the suggesting principle. The same man is not the same in this respect at all periods of life, in all circumstances, or at all hours. As there are persons whose general character is gloomy or cheerful, we have in like manner our peculiar days or moments in which we pass from one of these characters to the other, and in which our trains of thought are tinctured with the corresponding varieties. A mere change of fortune is often sufficient to alter the whole cast of sentiment. Persons in possession of public station, and power, and affluence, are accustomed to represent affairs in a favorable light; the disappointed competitors for these to represent all in the most gloomy light. Much of this, at least, is fairly ascribable to the difference of coloring, in which objects appear to the successful and the unsuccessful.

8. The temporary diversities of state that give rise to varieties of suggestion are not mental only but corporeal. The extreme cases of intoxication or actual delirium need not be referred to for the copious flow of follies which a little wine or a few grains of opium may cause to proceed from the proudest reasoner. In circumstances less striking, how different are the trains of thought in health and sickness, after a temperate meal and after a luxurious excess! It is not to the animal powers only that the burthen of digestion may become oppressive, but to the intellectual also; and often to the intellectual powers or functions more than to the animal.

9. Habit also has much influence in modifying the suggesting principle. When men of different mental habits, or of different professions, observe the same circumstances, listen to the same story, or peruse the same book, their subsequent suggestions are far from being the same; and could the future differences of the associate feelings that are to rise be foreseen by us at the time, we should probably be able to trace many of them to former professional peculiarities, which are thus unfortunately apt to be more and more aggravated by the very suggestions to which they have themselves given rise.

The interesting nature and probable availableness of much of the above have induced us to transcribe from Dr. Brown's lectures at considerable length; and it happened to be such as to require little modification for our purpose. On what he entitles 'The degree of liveliness of the suggesting feelings influences greatly that of the feelings suggested, and the virtual co-existence of feelings;' there is, like the title of the discussion itself, a good deal that approaches to mysticism, and not a little of over-refinement. There is no doubt something of momentary illusion in such instances as he has adduced (and he might have given that of Dr. Johnson on one of his last visits to his native place getting up on the bough of a tree, and swinging as if he had been actually mad); but whether they are to be satisfactorily accounted for in the manner attempted, may leave some doubt. The anecdotes quoted from the late Dr. Rush of Philadelphia are striking, and the first of them may perhaps be turned to good account by persons who may be placed in similar circumstances with the narrator.

'During the time,' says Dr. Rush, 'I passed at a country school in Cecil county in Maryland, I often went on a holiday, with my schoolmates, to see an eagle's nest upon the summit of a dead tree in the neighbourhood of the school, during the time of the incubation of that bird. The daughter of the farmer in whose field this tree stood, and with whom I became acquainted, married, and settled in this city about forty years ago. In our occasional interviews, we now and then spoke of the innocent haunts and rural pleasures of our youth, and among other things of the eagle's nest in her father's field. A few years ago I was called to visit this woman when she was in the lowest stage of a typhus fever. Upon entering her room I caught her eye, and with a cheerful tone of voice, said only, The eagle's nest. She seized my hand without being able to speak, and discovered strong emotions of pleasure in her countenance, probably from a sudden association of all her early domestic connexions and enjoyments with the words I had uttered. From that time she began to recover. She is now living, and seldom fails, when we meet, to salute me with the echo of the eagle's nest.'

An anecdote like this in the midst of a metaphysical discussion will be regarded by the general reader as a rose in the desert, or a lily among thorns. The old African is a lively instance of the principle and power of association or suggestion.

'An old native African obtained permission from his master, some years ago, to leave home, in order to see a lion that was conducted as a show through the state of New Jersey. The moment he saw him, in spite of the torpid habits of mind and body contracted by fifty years' slavery, he was transported with joy, which he vented by jumping, dancing, and loud acclamations. He had been familiar with that animal, when a boy, in his native country; and the sight of him suddenly poured upon his mind the recollection of all his enjoyments, from liberty and domestic endearments, in his own country, in the early part of his life.' No doubt the

thoughts and feelings of the old African on this occasion were as different from what ours would be in viewing a lion as if the object itself were wholly different.

On 'the reduction of certain supposed faculties to simple suggestion,' we consider Dr. Brown as very successful. We shall as briefly as possible give the more remarkable observations.

The supposed intellectual power of conception, as distinct from association or suggestion, is founded on mistake respecting the nature of the latter. The power of conception and the power of association or suggestion are the same, both being only that particular susceptibility of the mind from which in certain circumstances conceptions arise: or, if the power of conception differ from the more general power of association, it is only as a part differs from the whole; as the power of taking a single step differs from the power of traversing a whole field; the power of drawing a single breath from the general power of respiration.

Memory is also resolvable into suggestion. Our remembrances are nothing more than conceptions united with a certain relation of time. They are conceptions of the past, felt as conceptions of the past; that is, felt as having a certain relation of antecedence to our present feelings. The remembrance is not a simple but a complex state of mind; and all which is necessary to reduce a remembrance to a mere conception is to separate from it a part of the complexity; that part of it which constitutes the notion of a certain relation of antecedence. We are conscious of our present feeling whatever it may be; for this is in truth only another name for our consciousness itself. The moment of the present time, at which we are thus conscious, is a bright point, ever moving, and yet as it were ever fixed, which divides the darkness of the future from the twilight of the past. The present moment then is a point which guides us in the most important of our measurements, in our retrospects of the past and our hopes of the future. The particular feeling of any moment before the present, as it rises again in our mind, would be a simple conception, if we did not think of it either immediately or indirectly in relation to some other feeling earlier or later. It becomes a remembrance when we combine with it this feeling of relation; the relation which constitutes our notion of time; for time as far as we are capable of understanding it, or rather of feeling it, is nothing more than the varieties of this felt relation, which in reference to one of the subjects of the relation we distinguish by the word before, in reference to the other by the word after. It is a relation which we feel nearly in the same manner as we feel the relation which bodies have to each other as co-existing in space. There is some point to which, in estimating distance of space, we refer the objects which we measure, as there is a point of time in the present moment, or in some event which we have before learned to consider thus relatively, to which directly or indirectly we refer the events of which we speak as past or future, or more or less recent. We are capable of considering a variety of events, all of which are felt by us to bear to that state of mind which constitutes our presen consciousness, some relation of priority or subsequence, which they seem to us to bear reciprocally to each other; and the variety of this relation obliges us to invent a general name for expressing them all. This general word invented by us for expressing all the varieties of priority and subsequence is time, a word, therefore, which expresses no actual reality, but only relations that are felt by us in the objects of our conception. To think of time is not to think of any thing existing of itself, for time is not a thing but a relation; it is only to have some conceptions of objects which we regard as prior and subsequent; and without the conception of objects of some kind, as subjects of the relation of priority and subsequence, it is as little possible for us to imagine any time, as brightness or dimness without a single ray of light, proportional magnitude without any dimensions, or any other relation without any other subject. When the notion of time, then, is combined with any of our conceptions, as in memory, that which is combined with the simple conception is the feeling of a certain relation. To be capable of remembering, in short, we must have a capacity of the feelings which we term relations, and a capacity of the feelings which we term conceptions, that may be the subjects of the relations; but with these two powers no other is requisite, no power of memory distinct from the conception and relation which that complex term denotes.

How different is this from the jargon of the schools with which we have been so long persecuted concerning time, duration, memory, and such everlasting topics for mysticism and folly to practise their philosophy upon! Dr. Brown seems to have here, as elsewhere indeed in the same way, to have fallen into a slight error from not studying the nature of words more. Time is not a general word invented by us for expressing all the varieties of priority and subsequence. We never invented it at all for any purpose whatever; though false philosophy among us as well as among others has tried to make it into something it never was and never could be: and we might as well say that terminus, of which we doubt not it is a corruption, or our word term, or dies, or period, or era, or epoch, or any word connected with our measuring as to priority and subsequence is a general word invented by us for such a purpose as that time is such an invention. We cannot but wonder too that Dr. Brown should seem to reverence such venerable absurdity as the remark of St. Austin upon the subject. If it be 'one of those subjects which grow more obscure beneath our very gaze,' why gaze at all? It was surely quite sufficient that Mr. Dugald Stewart had commented very fully on the noted text of St. Austin.

With much other false theory or idle guesses about memory, put forth with a philosophic air of importance, it has been said that there is a species of it which is under our control, or that in some respects this faculty or power is subject to our volition as much as muscular motion. On this Dr. Brown justly remarks that this is nothing but memory combined with desire, and

which is commonly called recollection; that to will any idea necessarily implies that we know what we will; and implies the absurdity in the supposed volition acting on memory of knowing and not knowing the same thing at the same moment of time; or of desiring to become possessed of what we have in our possession already. What is termed voluntary recollection, whether direct or indirect, is nothing more than the co-existence of some vague and indistinct desire with our simple trains of suggestion.

In estimating the power of memory, in all its striking diversities in different individuals, it is necessary to guard against some prevailing errors. A good memory has fallen into a sort of proverbial disrepute, as unfriendly to judgment, or indicative of a defect in the nobler qualities of intellect. On this subject we have a very striking illustration in some theories of lord Kames, of the correctness of the remark we have quoted from Mr. Playfair. Men think they are reasoning from fact and experience, when in reality they are only reasoning from a mixture of truth and falsehood. The only end answered by facts, so incorrectly apprehended, is that of making error more incorrigible. 'In the minds of some persons,' says lord Kames, 'thoughts and circumstances crowd upon each other by the slightest connexions. I ascribe this to a bluntness in the discerning faculty; for a person who cannot accurately distinguish between a slight connexion and one that is more intimate is equally affected by each: such a person must necessarily have a great flow of ideas, because they are introduced by any relation indifferently; and the slighter relations, being without number, furnish ideas without end. On the other hand, a man of accurate judgment cannot have a great flow of ideas; because the slighter relations, making no figure in his mind, have no power to introduce ideas. And hence it is that accurate judgment is not friendly to declamation or copious eloquence. This reasoning is confirmed by experience; for it is a noted observation, that a great or comprehensive memory is seldom connected with a good judgment.'

In all this confirmation of experience there is a mixture of truth, but there is as great a mixture of error. It would seem, according to this philosopher, that a bad memory is an indispensable requisite to a good judgment; a very comfortable doctrine to idle boys and to old philosophers, who have almost all complained or boasted of a bad memory.

It is not a good memory in its best sense, as a rich and retentive store of conceptions, that is unfriendly to intellectual excellence, but a memory of which the predominant tendency is to suggest objects and images which existed before, exactly as they did previously exist, according to the mere relations of contiguity. The richer the memory, the more copious will be the suggestions of analogy which constitute invention. It is the quality of memory as suggesting objects in their old and familiar sequences of contiguity, not the quantity of the store of suggestions, that is unfriendly to genius; though this very difference of quality may, to superficial observers, seem like a difference of the quantity of the actual power. It is not from any defect of memory that fewer of the ideas which prevail in common conversation arise to a mind of accurate judgment; but because such a mind does not feel the same interest in them, or assign the same importance to them as the voluble Mrs. Quickly: in such a mind the prevailing tendencies of suggestion are of a species that have little relation to mere dates, and the trivial occurrences which are the ordinary topics of familiar discourse.

In extemporary eloquence the flow of mere words may and will be more copious in him who is not accustomed to dwell on the permanent relations of objects, but on the slighter circumstances of perception and local connexion; and he will doubtless be the most ready and voluble and effective orator, ad captandum vulgus. This only proves that he has a different kind, not a richer memory, when compared with a more profound and more accurate reasoner; the whole series of whose suggestions is greater in real amount than the number of those which rise so promptly to the mind of a superficial thinker. The great difference is, as so often remarked, the wealth of the one consists in plenty of small but ready money; that of the other is more rare and massy, and rather deposited than carried about for current use, or to be exhibited to the vulgar gaze.

The next part of the mental phenomena (for, as the term has been introduced, it is somewhat convenient at times) is imagination, usually made to figure as a very prominent, distinct, faculty, power, or entity of the mind. We not merely perceive objects, and conceive or remember them simply as they were before, but we have the power of combining them in various new assemblages into a new and varied universe, with every succession of our thought. The materials of which we form them exist in every mind, but they exist there only as the stones in the quarry, that require little more than mechanic labor to convert them into common dwellings, but which rise into palaces and temples at the command of architectural genius.

Our limits will not permit us to attempt an abridgment of Dr. Brown's interesting discussion, in resolving imagination into suggestion. His analytic process, we think, not only ingenious and minute, but perfectly successful and satisfactory. He has effectually dispelled much false theory—he has thrown down the cumbrous complexity of his metaphysical predecessors in Scotland. But we can make room for only a few specimens.

Imagination has been generally regarded as implying a voluntary selection and combination of images, for the production of compounds different from those which nature exhibits. This opinion is certainly false, in part at least. We have seen, in considering some other mental processes, that they assume a very different appearance when united with desire. Thus mere perception when united with desire becomes attention,—memory becomes recollection. A similar difference is produced by the union of desire with that spontaneous suggestion of

images called imagination, which may be considered therefore as existing without desire, or as existing in combination with desire or intention.

This distinction is so obvious that every person who is at all in the practice of looking inwards, or of consulting his consciousness, must be aware of it; and must have as firm a belief of it as of his identity: it is explicitly and fully stated within the compass of the few sentences quoted from Hobbes in a preceding part. That there is imagination, says Dr. Brown, or new combinations of images and feelings unaccompanied with any desire, and consequently altogether void of selection, is as true as that there is memory without intentional reminiscence, or recollection of the trains of our thought. Our conceptions often rise simply as they have existed before; they rise often mixed in various forms and proportions, as they never have existed before; and in both cases equally without any desire on our part. We as little will the various scenery of our reveries, and all the strange forms which seem to people them, as we will our dreams, or as we will the intrusion of unpleasant thoughts, remembrances, or anticipations, which we are intensely desirous of banishing from our minds, or as we will the conception of any one with whom we are acquainted, when the image of him instantly arises merely on reading his name, or seeing his portrait.

The momentary groups of images that arise independently of any desire, design, or choice on our part, and arise in almost every minute to almost every mind, constitute by far the greater number of our imaginations; and, to suppose predetermining selection necessary to every new complex conception, would therefore be almost to annihilate imagination itself. Such then is imagination, considered, as it most frequently occurs, without any concomitant desire—a mode of the general capacity of simple suggestion, and nothing more. But there are, unquestionably, cases in which desire, design, or intention of some sort, accompanies it during the whole or the chief part of the process; and it is of these cases chiefly that we are accustomed to think, in speaking of this supposed power or faculty. Such is the frame of the mind, in composition of every species, in prose or verse. In this state, conceptions follow each other, and new assemblages are formed. It is a continued exercise of imagination: what then is the analysis of our feelings in this state of voluntary thought, when there is a desire of forming new groups of images, and new groups of images arise?

To sit down to compose is to have a general notion of some subject which we are about to treat, with the desire of developing it, and the expectation, or perhaps the confidence, that we shall be able to develope it more or less fully. The desire, like every other vivid feeling, has a degree of permanence which only our vivid feelings possess; and, by its permanence, tends to keep the accompanying conception of the subject, which is the object of the desire, also permanent before us; and, while it is thus permanent, the usual spontaneous suggestions take place—conception following conception in rapid but relative series, and our judgment, all the time, approving and rejecting, according to those relations of fitness and unfitness to the subject which it perceives in the parts of the train. Such seems to be a faithful picture of the state or successive states of the mind, in the process of composition. It is not the exercise of a single power, but the development of various susceptibilities, of desire, of simple suggestion, by which conceptions rise after conception,—of judgment, or relative suggestion (presently to be treated of) by which a feeling of relative fitness or unfitness arises, on the contemplation of the conceptions that have thus spontaneously presented themselves. We think of some subject; the thought of this subject induces various conceptions related to it. We approve of some, as having a relation of fitness for our end, and disapprove of others as unfit. We may term this complex state, or series of states, imagination, or fancy, and the term may be convenient for its brevity. But, in using it, we must not forget that the term, however brief and simple, is still the name of a state that is complex, or of a succession of certain states; that the phenomena comprehended under it, being the same in nature, are not rendered, by this use of a mere word, different from those to which we have already given peculiar names, expressive of them as they exist separately; and that it is to the classes of these elementary phenomena, therefore, that we must refer the whole process of imagination in our philosophic analysis, unless we exclude analysis altogether, and fill our mental vocabulary with as many names of powers as there are complex affections of the mind. According to our analysis, then, there is no operation of any distinct power, or faculty (called imagination), but merely the rise of various images according to the ordinary laws of simple suggestion, in coexistence with feelings that arise from some other common principles of the mind, particularly desire, and the feeling of relation.

Through the whole of this discussion the lecturer must have been in a most enviable state of mind, and he appears to more than usual advantage as an intellectual anatomist or analyst, whichever image of him we may choose to adopt. The mastery of his metaphysical genius is such as to seem to twirl or play with the most difficult part of his subject, as if enjoying an intellectual amusement, rather than engaged in a gymnastic contest.

A lecture is devoted to the reduction of habit into suggestion, and refutes with abundant ease the notion of Dr. Reid, who, of course, ascribes the effects of habit to a peculiar ultimate principle, faculty, power, or potentate of the mind; and Hartley's famous vibratiuncle theory. Perhaps Dr. Brown might have been better employed than in disturbing its last moments: it might have been suffered to expire in peace, and die a natural death. One paragraph concerning habit is all that our limits will permit us to transcribe.

To explain the influence of habit, in increasing the tendency to certain actions, it must be remarked, that the suggesting influence, which is usually expressed in the phrase association of ideas (though that very improper phrase

would seem to limit it to our ideas or conceptions only, and has unquestionably produced a mistaken belief of this partial operation of the general influence) is not limited to these more than to any other states of the mind, but occurs also with force in other feelings, which are not commonly termed ideas or conceptions; that our desires, or other emotions, for example, may, like them, form part of our trains of suggestion; and that it is not more wonderful, therefore, that the states of the mind which constitute certain desires, after frequently succeeding certain perceptions, should, on the mere renewal of the perceptions, recur once more, than that any one conception should follow in this manner any other conception,—that the mere picture of a rose, for example, should suggest its fragrance; or that verses, which we have frequently read, should rise once more successively in our memory, when the line which precedes them has been repeated to us, or remembered by us. To him who has long yielded servilely to the practice of intoxication, the mere sight or the mere conception of the poisonous beverage to which he has sacrificed his health, and virtue, and happiness, will induce almost as if mechanically the series of mental affections on which the worse than animal appetite, and the muscular motions necessary for gratifying it, depend. Perhaps, at the early period of the growth of the passion, there was little love of the wine itself, the desire of which was rather a consequence of the pleasure of gay conversation that accompanied the too frequent draught. But, whatever different pleasures may originally have accompanied it, the perception of the wine, and the draught itself, were frequent parts of the complex process; and, therefore, those particular mental states which constituted the repeated volitions necessary for the particular muscular movements; and it is not wonderful, therefore, that all the parts of the process should be revived by the mere revival of a single part. What is called the power of habit is thus suggestion, and nothing more. The sight of the wine before him has co-existed innumerable times with the desire of drinking it. The state of mind, therefore, which constitutes the perception, induces, by the common influence of suggestion, that other state of mind which constitutes the desire, and the desire all those other states or motions which have been its usual attendants.

In the lecture (XLIV.) on The Influence of Particular Suggestions on the Intellectual and Moral Character, are many very important remarks; but they are not strictly metaphysical, and we can only quote a few of them.

Much of what is commonly called genius or of the secondary direction of genius which marks its varieties, and gives it a specific distinctive character, depends on accidents of the slightest kind that modify the general tendencies of suggestion, by the peculiar liveliness which they give to certain trains of thought. We are told in the Life of Chatterton, that, in his early boyhood, he was reckoned of very dull intellect, till he 'fell in love,' as his mother expressed it, with the illuminated capitals of an old musical manuscript in French, from which she taught him his letters; and a black-letter bible was the book from which she afterwards taught him to read. It is impossible to think of the subsequent history of this wonderful young man, without tracing a probable connexion of those accidental circumstances, which could not fail to give a peculiar turn to certain conceptions, with the character of that genius which was afterwards to make gray-headed erudition bend before it, and to astonish at least all those on whom it did not impose.

The illustrious French naturalist, Adanson, was in very early life distinguished by his proficiency in classical studies. In his first years at college he obtained the highest prizes in Greek and Latin poetry, on which occasion he was presented with the works of Pliny and Aristotle. The interest which such a circumstance could not fail to give to the works of these ancient enquirers into nature, led him to pay so much attention to the subjects of which they treated, that when he was scarcely thirteen years of age he wrote some valuable notes on the volumes that had been given to reward his studies of a different kind.

Vaucanion, the celebrated mechanician, who, in every thing which did not relate to his art, showed so much stupidity that it has been said of him, that he was as much a machine as any of the machines which he made,—happened, when a boy, to be long and frequently shut up in a room, in which there was nothing but a clock, which, therefore, as the only object of amusement, he occupied himself with examining, so as at last to discover the connexion and uses of its parts; and the construction of machines was afterwards his constant delight and occupation. The biography of many other eminent men might be referred to for multitudes of similar incidents, that appear to correspond, with an exactness more than accidental, with the striking peculiarities of character afterwards displayed by them.

Speaking of the prejudice for antiquity and established authorities in literature, we have the following just remark, which in our opinion applies to many of the admirers, or rather applauders, of Locke (for men can applaud in the dark) as fitly as if it had been made for them. How many are there who willingly join in expressing veneration for works which they would think it a heavy burden to read from beginning to end! Indeed this very circumstance, when the fame of an author has been well established, rather adds to his reputation than diminishes it; because the languor of a work of course cannot be felt by those who never take the trouble of perusing it, and its imperfections are not criticised, as they otherwise would be, because they must be remarked before they can be pointed out, while the more striking beauties, which have become traditionary in quotation, are continually presented to the mind. There is much truth, therefore, in the principle, whatever injustice there may be in the application of the sarcasm of Voltaire on the Italian poet, Dante, that 'his reputation will now continually be growing greater and greater, because there is now nobody who reads him.'

We proceed now to a most important part of Dr. Brown's discussions, On the Phenomena (we wish he could have done without this pompous term, which induces some confusion whereever it occurs) of Relative Suggestion. It is an arduous task to give the essential particulars of the extended whole in a small compass, as a map of a large country on a very reduced scale; but we shall do the best we can.

We have seen that there are many internal states or affections of the mind which arise simply in succession in the floating imagery of our thought, without involving any notion of the relation of the preceding objects or feelings to each other, and which have been classed under the head of simple suggestion. But there is an extensive order of our feelings which involve the notion of relation, and which consist, indeed, in the mere perception of a relation of some sort. To these feelings of mere relation, as arising directly from the previous states of mind which suggest them, we have given the name of relative suggestions—meaning by this term very nearly what is meant by the term comparison, when the will or intention which the word seems necessary to imply (but which is far from necessary to the suggestions of relation), is excluded; or what is meant at least in the more important relations by the term judgment—if not used (as it often is in vague popular language) to denote the understanding, or mental functions in general; and if not confined (as it usually is in books of logic), to the feeling of relation in a single proposition, but extended to all the feelings of relation, in the series of propositions which constitute reasoning; since these are, in truth, only a series of feelings of the same class as that which is involved in every simple proposition. Whether the relation be of two or of many external objects, or of two or of many affections of the mind, the feeling of this relation arising in consequence of certain preceding states of mind is what we term relative suggestion. That is the simplest phrase which we can employ for expressing without any theory the mere fact of the rise of certain feelings of relation after certain other feelings which precede them.

By an original tendency or susceptibility of the mind we are instantly sensible of the relation of objects in certain respects as really as we are sensible of their existence, or have that inward feeling which we call perception. As there are various species of sensation or perception, so there are various species of relations. Their number indeed, even of external things, is innumerable. The more numerous, however, these relations, the more necessary it is to have some arrangement.

All our relations (or relations felt by us) are either of external objects, or of our own internal affections or states of the mind, considered as merely co-existing without any reference to time, or considered as successive with reference to time. To take an example of each kind: we feel that the one half of four is to twelve as twelve to seventy-two; and we feel this kind of relation merely by considering the numbers together, without any regard to time. No notion of change or succession is involved in it. The relation was, and is, and will for ever be the same—as often as the numbers may be distinctly conceived and compared. On the other hand, we think of summer; we consider the warmth of the sky and the profusion of flowers. We think of the cold of winter, and of flowerless fields and frozen rivulets. The warmth and the cold of the different seasons we regard as the causes of the different appearances. In this case, as in the former, we feel a relation, but it is a relation of antecedence and consequence, to which the notion of time or change or succession is so essential, that without it the relation could not be felt.

Our first class of relations, then, are those of which the subjects are regarded without reference to time. To this order of real co-existence as in matter, or of seeming co-existence as in the complex states of the mind, belong the relation of position, resemblance or difference, proportion, degree, comprehension.

We look at a number of men as they stand together. If we merely perceived each individually, or the whole as one complex group, we should have no feeling of relation; but we remark one—we observe who is next to him, who second, and who third; who stands on the summit of a little eminence above all the rest; who in the plain below. This is the feeling of the relation of position; that is, our mind exists in those states which constitute this feeling in reference to the number of men contemplated or viewed standing together.

We see two flowers of the same tints and form. We lift our eyes to two cliffs of corresponding outline. We look at a picture, and think of the well-known face which it represents. We listen to a ballad, and seem almost to hear again some kindred melody which it wakes in our remembrance. In each of these cases, if the relative suggestion take place, our mind, after existing in the states which constitute the perception, or the remembrance of the two similar objects, exists immediately in that state which constitutes the feeling of resemblance, as it exists in the state which constitutes the feeling of difference, when we think of certain circumstances in which objects, though similar, perhaps, have in other respects no correspondence or similarity whatever. The above then is the feeling of a relation of resemblance or difference.

We think of the vertical angles formed by two straight lines, which cut one another; of the pairs of numbers, four and sixteen, five and twenty: of the dimensions of the columns and their bases and entablatures, in the different orders; and our mind exists immediately in that state which constitutes the feeling of proportion.

We hear one voice, and then a voice which is louder. We take up some flowers, and smell first one, and then another, more or less fragrant. We remember many days of happiness, spent with friends who are far distant; and we look forward to the day of still greater happiness, when we are to meet again. In these instances of spontaneous comparison our mind exists in that state which constitutes the feeling of degree.

We consider a house, and its different apart-

ments; a tree, and its branches, and stems, and foliage; a horse, and its limbs, and trunk, and head. Our mind, which had existed in the states which constituted the simple perception of these objects, begins immediately to exist in that different state which constitutes the feeling of the relation of parts to one comprehensive whole.

In these varieties of relative suggestion, some one of which, as you will find, is all that constitutes each individual judgment, even in the longest series of our ratiocination, nothing more is necessary to the suggestion or rise of the feeling of relation than the simple previous perceptions, or conceptions, between the objects of which the relation is felt to exist. When we look at two flowers it is not necessary that we should have formed any intentional comparison. But the similitude strikes us, before any desire of discovering resemblance can have arisen. We may, indeed, resolve to trace, as far as we are able, the resemblance of particular objects, and may study them accordingly; but this very desire presupposes, in the mind, a capacity of relative suggestion, of which it avails itself; in the same manner as the intention of climbing a hill, or traversing a meadow, implies the power of muscular motion, as a part of our physical constitution.

Besides a thousand other delights and benefits, it is to the results of resemblances that we owe all classification, and, consequently, almost all that is valuable in language. That classification is founded on the relation of similarity of some sort, in the objects classed together, and could not have been formed if the mind, in addition to its primary powers of external sense, had not possessed that secondary power, by which it invests with certain relations the objects which it perceives, is most evident. All which is strictly sensitive in the mind might have been the same as now; and the perception of a sheep might have succeeded a thousand times the perception of a horse without suggesting the notion which leads us to form the general term quadruped, or animal, inclusive of both. The relation is truly no part of the object perceived by us, and classed as relative and correllative, each of which would be precisely the same in every quality which it possesses, and in every feeling which it directly excites, though the others with which it may be classed had no existence. It is from the laws of the mind which considers them that the relation is derived; not from the laws or direct qualities of the objects considered. But for our susceptibilities of those affections, or states of the mind, which constitute the feeling of similarity, all objects would have been to us, in the scholastic sense of the phrase, things singular, and all language, consequently, nothing more than the expression of individual existence. Such a language, it is very evident, would be of little service in any respect, and of no aid to the memory, which it would oppress rather than relieve. It is the use of general terms; that is, of terms founded on the feeling of resemblance, which alone gives to language its power, enabling us to condense, in a single word, the innumerable objects which, if we attempted to grasp them all individually in our conception, we should be as little able to comprehend, as to gather all the masses of all the planets in the narrow concavity of that hand which a few particles are sufficient to fill, and which soon sinks oppressed with the weight of the few particles that fill it.

That man can reason without language of any kind, and consequently without general terms, though the opposite opinion is maintained by many very eminent philosophers (not by Hobbes however, who expresses in substance the same opinion as Dr. Brown), seems not to admit of any reasonable doubt: or, if it required any proof, it would seem to be sufficiently shown by the very invention of the language which involves these general terms; and still more sensibly by the conduct of the uninstructed deaf and dumb; to which, also, the evident marks of reasoning in the other animals,—of reasoning as unquestionable as the instincts that mingle with it, may be said to furnish a very striking additional argument from analogy. But it is not less certain that, without general terms, reasoning must be very imperfect, and scarcely worthy of the name, when compared with that noble power which language has rendered it. The art of definition, which is merely the art of fixing in a single word or phrase the particular circumstance of agreement of various individual objects, which, in consequence of this feeling of relation we have chosen to class together, gives us certain fixed points of reference, both for ourselves and others, without which it would be impossible for us to know the progress which we have made impossible to remember accurately the results even of a single reasoning, and to apply them, with profit, to future analysis. Nor would knowledge be vague only; it would, but for general terms, be as incommunicable as vague; for it must be remembered that such terms form almost the whole of the great medium, by which we communicate with each other.

The perception of objects, the feeling of their resemblance in certain respects, the invention of a name for these circumstances of felt resemblance: what can be more truly and readily conceivable than this process! And yet, on this process, apparently so very simple, has been founded all that controversy, as to universals, which so long distracted the schools; and which far more wonderfully (for the distraction of the schools by a few unintelligible words scarcely can be counted wonderful) continues still to perplex philosophers with difficulties which themselves have made, with difficulties which they could not even have made to themselves, if they had thought for a single moment of the nature of that feeling of the relation of similarity which we are now considering.

We feel, in transcribing the words of the lecturer, as if partaking in his triumph. This lecture alone, this portion of it which we have extracted, is worth all the contributions of discovery, and data, and phenomena, to the science of mind, we say not of Dr. Reid and his compeers and illustrious pupil, but of all the intellectual philosophers since the days of Hobbes, with Hartley and Hercules at their head. This alone would have proclaimed Dr. Brown worthy of moving up to the highest place of metaphy

sical dignity, and of taking his station at the right hand of the philosopher of Malmesbury. We regard the discussion of relative suggestion as one of the mightiest achievements and proudest triumphs of human reason. But we have neither time nor space to give vent to all our feelings, or to point out the grounds on which our admiration rests, or the claims of Dr. Brown not only to our applause, but to our gratitude as an intellectual benefactor of the highest order. Transcription is in itself, abstractedly considered, irksome, laborious work, and we would rather give the ideas of the lecturer in our own words were we not fearful of marring his reasoning. We must transcribe his recapitulation of the preceding lecture almost verbatim.

'Having brought to a conclusion my remarks concerning simple suggestion, I entered, in my last lecture, on the consideration of those states of mind which constitute our feelings of relation, the results of that peculiar mental tendency to which, as distinguished from the simple suggestion that furnishes the other class of our intellectual states of mind, I have given the name of relative suggestion. The relations which we are thus capable of feeling, as they rise by internal suggestion, on the mere perception or conception of two or more objects, I divided, in conformity with our primary division of the objects of physical enquiry, into the relations of co-existence, and the relations of succession, according as the notion of time or change is or is not involved in them; and the former of these, the relations that are considered by us without any regard to time, I arranged in subdivisions, according to the notions which they involve, 1. Of position; 2. Resemblance or difference; 3. Of degree; 4. Of proportion; 5. Of comprehensiveness, or the relation which a whole bears to the separate parts that are included in it.

'These various relations I briefly illustrated in the order in which I have now mentioned them, and showed how very simple that mental process is by which they arise; as simple, indeed, and as easily conceivable, as that by which the primary perceptions themselves arise. On some of them, however, I felt it necessary to dwell with fuller elucidation; not on account of any greater mystery in the suggestions on which they depend, but on account of that greater mystery which has been supposed to hang about them.

'A great part of my lecture, accordingly, was employed in considering the relation of resemblance, which, by the general notions and corresponding general terms that flow from it, we found to be the source of classification and definition, and of all that is valuable in language.

'A horse, an ox, a sheep, have, in themselves, as individual beings, precisely the same qualities, whether the other be or be not considered by us at the same time. When, in looking at them, we are struck with their resemblance in certain respects, they are themselves exactly the same individuals as before; the only change which has taken place being a feeling of our own mind. And, in like manner, in the next stage of the process of verbal generalisation, when, in consequence of this feeling of relation in our own minds, we proceed to term them quadrupeds or animals, no quality has been taken from the objects which we have ranged together under this new term, and as little has any new quality been given to them. Every thing in the objects is precisely the same as before, and acts in precisely the same manner on our senses, as when the word quadruped or animal was uninvented. The general terms are expressive of our own internal feelings of resemblance, and of nothing more; expressive of what is in us, and dependent wholly on laws of mind, not of what is in them, and directly dependent in any degree on laws of matter.

'That, in looking at a horse, an ox, a sheep, we should be struck with a feeling of their resemblance in certain respects; that to those respects in which they are felt to resemble each other we should give a name, as we give a name to each of them individually, comprehending under the general name such objects only as excite, when considered together with others, the feeling of this particular relation; all this has surely nothing very mysterious in it. It would, indeed, be more mysterious, if, perceiving the resemblance of objects that are constantly around us, we did not avail ourselves of language, as a mode of communicating to others our feeling of the resemblance, as we avail ourselves of it in the particular denomination of the individual, to inform others of that particular object of which we speak; and to express the common resemblance which we feel by any word, is to have invented already a general term, significant of the felt relation. The process is in itself sufficiently simple; and, if we had never heard of any controversies with respect to it, we probably could not have suspected, that the mere giving of a name to resemblances which all perceive, and the subsequent application of the name only where the resemblance is felt, should have been thought to have any thing in it more mysterious than the mere giving of a name to separate objects which all perceive, and the repetition of that name when the separate objects are again perceived. It assumes, however, immediately an air of mystery when we are told, that it relates to the predicables of the schools, and to all that long controversy with respect to the essence of universals, which divided not merely schoolman against schoolman, but nation against nation; when kings and emperors, who had so many other frivolous causes of warfare without the addition of this, were eager to take up arms, and besiege towns, and cover fields with wounded and dead, for the universal à parte rei. It is difficult for us to think that that could be simple which could produce so much fierce contention; and we strive to explain in our own mind, and, therefore, begin to see many wonderful, and perhaps unintelligible, or at least doubtful things, in phenomena which we never should have conceived to require explanation, if others had not labored to explain them, by clouding them with words.

'It is with many intellectual controversies as with the gymnastic exercises of the arena; the dust, which the conflict itself raises, soon darkens that air which was clear before; and the longer the conflict lasts the greater the dimness which arises from it. When the combatants are very

many, and the combat very long and active, we may still, indeed, be able to see the mimickry of fight, and distinguish the victors from the vanquished; but even then we scarcely see distinctly; and all which remains when the victory at last is won, or when both parties are sufficiently weary and choked with dust, is the cloud of sand which they have raised, and perhaps some traces of the spot where each has fallen.

'That the subject of generalisation should have appeared mysterious to the schoolmen is not very surprising. But I must confess that there is nothing in the history of our science which appears so wonderful as that any difficulty (at least any difficulty greater than every phenomenon of every kind involves) should now be conceived to attach to this very simple process; and especially that philosophers should be so nearly unanimous in an opinion on the subject, which though directly opposed to the prevalent error in the ancient schools is not the less itself an error.

In the view which is taken of the process of generalisation (as of every other process) there may be error in two ways; either by adding to the process what forms no part, or by omitting what does truly form a part of it. Thus, if we were to say, that, between the perception of a horse and sheep, and the feeling of their resemblance in a certain respect, there intervenes the presence of some external independent substance; some universal form or species of a quadruped, distinct from our conceiving mind, which acting on the mind, or being present with it, produces the notion of a quadruped, in the same way as the presence of the external horse or sheep produced the perception of these individually; we should err, in the former of these ways, by introducing into the process something of which we have no reason to suppose the existence, and which is not merely unnecessary, but would involve the process in innumerable perplexities and apparent inconsistencies, if it did exist. This redundance would be one species of error; but it would not less be an error (though an error of an opposite kind), were we to suppose that any part of the process does not take place; that, for example, there is no relative suggestion, no rise in the mind of an intervening general notion of resemblance, before the invention and employment of the general term, but the mere perception of a multitude of objects, in the first place; and then, as if in instant succession, without any other intervening mental state whatever, the general names under which whole multitudes are classed.

'I have instanced these errors of supposed excess and deficiency, in the statement of the process, without alluding to any sects which have maintained them. But the two opposite errors which I have supposed are the very errors involved in the opinions of the realists and nominalists; the great combatants in that most disputatious of controversies, to which I have before alluded; a controversy which in the strong language of John of Salisbury, even at that early period, of which alone he could speak, had already employed fruitlessly more time and thought than the whole race of the Cæsars had found necessary for acquiring and exercising the sovereignty of the world.

'Realism, which descended from Pythagoras, Plato, and Aristotle, as the orthodox inheritance in metaphysics of the schoolmen, is now universally admitted to be glaringly absurd: it has not been so hitherto, however, with Nominalism, which was espoused first by Roscelinus and after him by Abelard, Luther, Hobbes, Berkeley, Hume, Dr. Campbell, and almost every philosopher of any note. Mr. Locke and Dr. Reid may be said to have had respectively some intermediate dark or confused notion of their own. The noted abstract or general triangle of the former has long been a subject of merriment. One of the most prominent and plausible nominalists is Mr. Horne Tooke, who holding that there is nothing general but terms, and that it is as absurd to speak of a complex idea as to call a constellation a complex star, was to accomplish wonderful logical things by his wonder-working etymology. In confidence or pretension he was almost a match for Kant the critic of pure reason. But after running his etymological race after the Northern lights, as the only infallible guides in the conduct of the understanding, he left poor human reason in the same general darkness and error in which he found it as an object of his benevolent regard or tender compassion. He did something it is true by etymology for the better understanding of language as an instrument of reasoning and a medium of thought; and he would have done more but for his blind credulity and over-weening affection towards the northern origin.' We wish Dr. Brown had studied and understood the nature and office of language as much as he did, or rather as much as his great metaphysical predecessor and prototype in most other respects, the philosopher of Malmesbury. In that case what would he not have effected? But we are unwise or unreasonable perhaps in wishing that he had been any thing but precisely what he was. But we must again permit him to address the reader and dispose of nominalism.

'Even in professing to exclude the general notion of resemblance, the nominalist unconsciously proceeds on it; and no stronger proof can be imagined of the imperfectedness of the view which his system gives of our generalisations than the constant necessity under which we perceive him to labor of assuming, at every stage of his argument, the existence of those very notions, or feelings of relative suggestion against which his argument is directed. The general term, we are told, is significant of all objects of a certain kind, or a particular idea is made to represent various other ideas of the same sort; as if the very doctrine did not necessarily exclude all notion of a kind or sort, independent of the application of the term itself. 'An idea,' says Berkeley, 'which considered in itself is particular, becomes general, by being made to represent or stand for all other particular ideas of the same sort;' and he instances this in the case of any particular length, an inch, for example; which, to a geometer, he says, becomes general, as it represents all particular lines whatsoever; so that what is demonstrated of it, is demonstrated

of all lines, or, in other words, of a line in general. It is truly inconceivable that he should not have discovered, in this very statement, that he had taken for granted the existence of general notions, the very states of mind which he denied; since, without these, there can be no meaning in the restriction of any sign to 'ideas of the same sort.'

But it is not necessary to accompany Dr. Brown farther in the process of a refutation of such mysticism and unmeaningness or absurdity as that of Berkeley and others in defence or definition of nominalism. The following is the conclusion of the whole.

'In the case of nominalism, as in many other cases, I have no doubt, notwithstanding the apparent extravagance of the paradox, that it is because the doctrine of the nominalists is very contrary to our feelings, we do not immediately discover it to be so. If it were nearer the truth we should probably discover the error which it involves much more readily. The error escapes us because our general terms convey so immediately to our mind that common relation which they denote, that we supply of ourselves, what is wanting in the process as described by the nominalist; the feelings of the circumstances of resemblance, specific or generic, that are to guide us in the application as they led us to the invention of our terms. We know what it is which he means, when he speaks of particular terms, or particular ideas, that became more generally significant by standing for ideas of the same sort, or the same order, or species, or genus, or kind; and we therefore make for him, by the natural spontaneous suggestions of our own mind, the extension and limitation which would be impossible on his own system. But for such an illusion it seems scarcely impossible to understand how so many, of the first names of which our science can boast, should be found among the defenders of an opinion which makes reasoning nothing more than a mere play upon words, or, at best, reduces very nearly to the same level the profoundest ratiocinations of intellectual, or physical, or mathematical philosophy, and the technical labors of the grammarian or the lexicographer.'

The system of the nominalists then, though more simple than that of the realists, is not, any more than it, a faithful statement of the process of generalisation. It is true as it rejects the existence of any universal form or species, distinct from our mere feeling of general resemblance. But it is false as it rejects the general relative feeling itself, which every general term denotes, and without which, to direct us in the extension and limitation of our terms, we should be in danger of giving the name of triangle as much to a square or circle, as to any three-sided figure. We perceive objects, we have a feeling or general notion of their resemblance, we express this general notion by a general term. Such is the process of which we are conscious; and no system which omits any part of the process can be a faithful picture of our consciousness.

We have alluded above to Mr. Locke's notable general triangle. As it is calculated to set his metaphysical mastery in a striking light, when he ventured to quit his guides and attempt originality, we quote the passage which may be found by the reader in turning to Book IV. chap. vii. sect. 9, of the Essay concerning Human Understanding:—'Does it not require some pains and skill,' says Mr. Locke, 'to form the general idea of a triangle (which is yet none of the most abstract, comprehensive, and difficult)? for it must be neither oblique nor rectangle, neither equilateral, equicrural, nor scalenon; but all and none of these at once. In effect it is something imperfect that cannot exist; an idea wherein some parts of several different and inconsistent ideas are put together.'

This is surely worthy of being preserved as a precious metaphysical relic of Mr. Locke, and in confirmation of the old testimony of Cicero respecting nothing being too absurd to be found in the writings of philosophers. Mr. Locke may be designated a conceptualist, to discriminate him (as intermediate) from the realists on the one extreme, and the nominalists on the other; but, in reference to either, his idea was confusion worse confounded. Dr. Brown is at some pains to show (as Mr. Stewart is indefatigable in showing, in reference to his making reflection a distinct origin of ideas), that Mr. Locke meant well in this matter: and none can have a higher opinion of his good intentions than we have. He was truly, in the very highest sense of the expression, a well-meaning man. As in all practical and less abstract concerns sensible and judicious, as a truly good man, as the friend of human improvement and happiness, as the advocate, and in some sense a father, of civil and religious liberty, or, at least, of just notions concerning them, we revere and love his memory. But we cannot prostrate our understanding to him as a metaphysical object of worship, or sincerely profess to admire him as possessed of extraordinary intellectual acuteness, originality, depth, or comprehension.

As an ulterior step, in the discussion of relative suggestion, Dr. Brown proceeds in the forty-eighth lecture to give an analysis of the process of reasoning; and we shall endeavour to extract from it what seems most essentially important.

'On that class of our relative suggestions which involves the feeling of the relation of the parts comprehended to the comprehending whole, it will be necessary to bestow some more illustration, that you may understand clearly the nature of the process of reasoning; that most important of all our mental processes, which logicians and metaphysicians have contrived to render so obscure, but which is in itself nothing more than a series of felt relations of this particular class in the instances of which I selected before, of a house and its apartments; a tree and its stems and foliage; a horse and its head and limbs and trunk. The relation which I have termed the relation of comprehension, or comprehensiveness, is so very obvious, that a mere allusion to it is sufficient, without any commentary.

'When I think of cases in which the relation is of a substance to parts that are themselves substances, as when I say that a room is a part of a house, or that a tree has branches, it is quite

evident that in these very simple propositions I merely state the relation of parts to a comprehending whole. But is the statement at all different when I speak, in the common forms of a proposition, of the qualities of objects; when I say, for example, that snow is white, man is capable of reasoning, the wisest of mankind is fallible? do I not merely state one of the many qualities, comprehended in that totality of qualities, which constitute the subject as known to me? I do not indeed divide a mass into its integral parts, but I divide a complex notion into its parts, or at least separate from that complexity a quantity which I feel to belong, and state to belong, to that complex notion from which I have detached it. It is as it were a little analysis and synthesis. I decompose, and, expressing to others the mental decomposition which I have made, I combine again the separated elements of my thought, not indeed in the same manner (for the analytic process is as different as matter is from mind), but with the same feeling of agreement or identity that rises in the mind of a chemist when he has reduced to one mass the very elements into which he had transmuted the mass, by some one of the analyses of his wonderful art.'

What then is reasoning (which is nothing more than a number of propositions consecutive in a certain order) but a continued series of analytical operations of this kind, developing the elements of our thought? In every proposition that which is affirmed is a part of that of which it is affirmed, and the proposition, however technical its language may be, expresses only the single feeling of this relation.

Whatever be the species of reasoning, however, it is necessary that the proportions which form the reasoning should follow each other in a certain order; for without this order, though each proposition might involve some little analysis, and consequently some little accession of knowledge, the knowledge thus acquired must be very limited. There could be no deduction of remote conclusions, by which the primary object of a distant proposition might be shown, through a long succession of analyses, to have properties which required all these various evolutions before they could themselves be evolved to view. In the proportional reasonings of geometry, we know well that the omission of a single proposition, or even a change of its place, might render apparently false, and almost inconceivable by us, a conclusion which, but for such omission or change of place of a few words of the demonstration, we should have adopted instantly, with a feeling of the absolute impossibility of resisting its evidence.

To constitute reasoning it is necessary that there should be some mutual relation of the subjects and predicates of the different propositions. The order of the different propositions is so arranged, as to present to us this mutual relation of the successive subjects and predicates; it is therefore of the utmost importance to our consecutive analyses, in the reasonings that are strictly analytic, and to our consecutive measurements in the reasonings which are proportional. On what does this order depend?

The common opinion on the subject makes this order a very easy matter. We have a certain sagacity, it is said, by which we find out the intervening propositions, and they are arranged in the proper order because we have discovered them to be suitable for our measurement, and put them in their proper places. 'Those intervening ideas which serve to show the agreement of any two others,' says Locke, 'are called proofs. A quickness in the mind to find out these intermediate ideas (that shall discover the agreement or disagreement of any other), and to apply them rightly, is, I suppose, that which is called sagacity.' And reason itself he elsewhere defines to be the faculty which finds out these means and rightly applies them. We need not quote the common expressions to the same purport which are to be found in other writers.

The sagacity of which Locke and other writers speak, may (since it is nothing more than a form of our simple suggestion itself) be reduced to that peculiar tendency of the suggesting principle, varying in different minds, of which we have before treated, when considering the secondary laws of suggestion in their relation to original genius. The same objects do not suggest to all the same objects even where past observation and experience may have been the same; because the peculiar suggestions of the objects, the relations of which are afterwards felt, depend in a great measure also on tendencies modified by long habit, and therefore varying in different individuals as these habits may have been different. To some minds (the common minds which in the great multitudes of our race think what others have thought, and do what others have done) the conceptions which form their trains of memory, that scarcely can be called trains of reflection, rise, as we have seen, according to the relation of mere contiguity, or former proximity in time, of the related images. The conceptions of minds of a higher order rise in almost infinite variety, because they rise according to a relation which does not depend on former co-existence of the very images themselves, but is itself almost infinitely various.

The differences of opinion in mankind, far from being wonderful, are such as must have arisen though there had been no other cause of difference than the variety of the conceptions, which by the simple laws of suggestion, occur in the various trains of thought of individuals, diversifying of course the order of propositions in their reasonings, and consequently the relation which the conclusion involves. The objects compared have, at every stage of the argument, been different; and the results of the comparison of different objects, therefore, cannot well be expected to be the same.

Having resolved the whole process of reasoning into simple suggestion, as so fully and clearl explained by him, Dr. Brown adverts to the syllogistic art, which so long reigned triumphant in the schools, and which still lingers in the fond embrace of a certain description of logical professors. We have already given the substance of his statement at the conclusion of the article LOGIC, to

which we refer the reader. The futility and absurdity of the syllogism are now almost universally admitted; and if any syllogistic admirers are to be found, on whom the remarks of Dr. Brown have had no effect, we know not that it would be of any use to reason with them. It may be enquired, however, if the old logic be exploded are we not to have something better as a substitute? In reply, our author justly remarks, 'The art of reasoning which a judicious logic affords is not so much the art of acquiring knowledge as the art of communicating it to others, or of recording it in the manner that may be most profitable for our own future advancement in the track which we have been pursuing. Its direct benefit to ourselves is rather negative than positive, teaching us the courses of error in our mental constitution, and in all the accidental circumstances of the language which we are obliged to use of the society in which we must mingle. Its office is to deliver us from what is false, rather than to confer on us what is true. Indeed, since we cannot, as already shown, produce directly in our mind any one conception, or any one feeling of relation, it is very evident that the influence of any art of reasoning on our train of thought must be indirect only.'

Men are fond of art and rules, but these have little of positive utility: they never yet made a good reasoner any more than a great poet. After all that has been said of the conduct of the understanding, the best rule of right reasoning that can be given is, Guard against the various causes of error and imposition, and particularly against that grand imposture the imposition of words. The great error of the theory of the syllogism (and it is an error which may operate when the syllogism itself is discarded) consisted in supposing that, because all our knowledge may be technically reduced in some measure to general maxims, these maxims have naturally a prior and paramount existence in our thought, and give rise to those very reasonings, which, on the contrary, give rise to them.

As has been fully shown, we trust, judgment, which makes such a figure in the language and theories of logicians and metaphysicians as a faculty or power of the mind, is nothing but a feeling of relation; nor is reason, which also makes such a figure as a sort of distinct if not independent faculty, any thing but a series of judgments or felt relations. 'Those,' says Dr. Brown, 'who ascribe judgment to man, ascribe to him also another faculty which they distinguish by the name of reason: though reasoning itself is found, when analysed, to be nothing more than a series of judgments. The whole is thus represented as something different from all the parts which compose it. Whether we reason syllogistically with the schoolmen, or according to those simple processes of thought which nature teaches, our reasoning is divisible into a number of consecutive judgments, or feelings of relation; and, if we take away these consecutive judgments, we leave nothing behind which can be called a ratiocination. In a simple proposition we take one step, or feel one relation; in an enthymeme we take two steps, or feel two relations; in a syllogism we take three steps, or feel three relations; but we never think, when we speak of the motion of our limbs, that the power of taking three steps differs essentially from the power of taking one; and that we must, therefore, invent new names of bodily faculties for every slight variety, or even every simple repetition of movement.

'The circumstance which led to the distinction of reason from judgment was not so much the mere length and mutual connexion of the series, as that mistake with respect to the power falsely ascribed to the mind, of finding out by some voluntary process the intervening propositions which serve as the medium of proof. The error of this is now, we trust, sufficiently manifest.

'Another faculty with which the mind has been enriched by systematic writers who have ranged the different states of the mind into many powers or faculties is abstraction; a faculty by which we are supposed to be capable of separating in our thoughts certain parts of our complex notions, and of considering them thus abstract from the rest. This supposed faculty, however, is not merely unreal but impossible, since every exertion of it would imply a contradiction. In abstraction the mind is supposed to single out a particular part of some one of its complex notions for particular consideration. But what is the state of the mind immediately preceding this intentional separation, its state at the moment in which the supposed faculty is conceived to be called into exercise? Does it not involve necessarily the very abstraction which it is supposed to produce? and must we not, therefore, in admitting such a power of voluntary separation, admit an infinite series of preceding abstractions, to account for a single act of abstraction? If we know what we single out, we have already performed all the separation which is necessary; if we do not know what we are singling out, and do not even know that we are singling out any thing, the separate parts of the complex whole, may, indeed, rise to our conception (as they do rise), but it cannot arise by the operation of any voluntary faculty.

'I have now,' he says, 'brought to a conclusion my analysis of the intellectual phenomena; and have endeavoured to show that, though commonly ascribed to many distinct faculties, they are all truly referrible only to two, the capacity of simple suggestion, which gives to us conceptions of external objects, formerly perceived, and of all the variety of our past internal feelings, as mere conceptions of fainter images of the past; and a capacity of relative suggestion by which the objects of our perception or conception that are themselves separate no longer appear to us separate, but are instantly invested by us with various relations that seem to bind them to each other, as if our mind could give its own unity to the innumerable objects which it comprehends.'

We have now followed the lecturer step by step through his whole course of intellectual investigation, and have omitted as little as possible of the topics that seemed most material. We cannot at present proceed with him to the consideration of our emotions, or, as commonly termed, passions; but we hope to bring him

soon again before the public in connexion with these. It remains that we very hastily say a few words concerning our task, concerning our author, and concerning the science or philosophy of mind as now presented by the investigations of the late professor of moral philosophy in the university of Edinburgh.

We know not what satisfaction or dissatisfaction our attempt in reference to Dr. Brown will give to our readers; we have not been able wholly to satisfy ourselves, and have only the consolation of the fullest consciousness that we meant well. We have endeavoured (often unsuccessfully we fear) to popularise the greatest metaphysician of the age, to bring him down to the level and within the reach of the perception and appreciation of the general reader. In this endeavour we have sincerely desired to confer honor on the one and a benefit on the other. We have, we trust, taken no unwarrantable liberties with the lectures, of which we have made so much use. In extracting from them we have altered, abridged, and extended by turns. Hence we have sometimes omitted quotation marks when quotations have been made almost verbatim; but we have, in these cases, both directly and indirectly apprised the reader that the truly great moral professor was addressing them. With readers who feel any interest in such enquiries, what we have done is calculated, as it is really intended, not to mar but to promote the reputation of Dr. Brown's Lectures on the Philosophy of the Human Mind. Thus much, candid reader, we have thought necessary to say in reference to ourselves. We willingly hasten away from self to the object of our admiration and gratitude.

The reader must be already fully aware that we estimate the intellectual merits of Dr. Brown very highly. We consider him as one of the most original, profound, comprehensive, and sound thinkers of any age or country. For metaphysical acuteness, and discriminative subtilty, and masterly analysation, he stands unrivalled. There is, indeed, an excess of this kind of excellence, which rather mars his general merits, the utility of his intellectual labors, and the measure of his fame. But take him for all in all, as an intellectual philosopher, we know of but one who has any title to dispute or divide with him the pre-eminence, a pre-eminence of the highest altitude above the reach of other aspirants. As to the northern lights that played, and all the stars that twinkled in the metaphysical hemisphere, they must hide their diminished heads in the presence of this glorious orb of day. Nothing but another night of metaphysics could render them beautiful and attractive: a voluntary descent into the deep well of scholastic notions and jargon would be almost necessary to render stars which once shone with much brilliancy any longer visible.

This may seem extravagance, and we may have put the case somewhat hyperbolically, but the reader must not suppose that we are unreserved admirers or blind idolaters of Dr. Brown. His excellencies are of the rarest and highest order, but they are not free from some alloy of defect. He will bear a favorable comparison with his distinguished metaphysical predecessor (who was unquestionably in part his prototype); but in some respects he is a complete contrast to the philosopher of Malmesbury. Dr. Brown is often too subtile, almost always too wordy, and consequently he is very generally deficient in the important article of lucidus ordo, or perspicuity. It is often, indeed, a very great intellectual exertion to understand him. His style is radically defective considered as a medium or instrument of imparting his conceptions, and is just the reverse of Hobbes's, as so happily characterised by Sheffield, duke of Buckingham. We may say of it frequently what he himself has said of time (considered as an abstract entity) by way of compliment to St. Austin and the illustrious pupil of Dr. Reid. 'Instead of growing clearer as we gaze upon it, it grows more obscure beneath our very gaze.' Indeed our greatest wonder of all is how he should have accomplished so much with such a bad instrument, or with such unskilful management of the verbal apparatus—the most demonstrative evidence, perhaps, that could have been given of his being possessed of that creative genius which gives a sort of omnipotent independence of means or instruments. We do not now wonder at what we have heard sneeringly said of him in his life-time, that his poetry was bad prose, and his prose bad poetry. It is richly intellectual and occasionally truly eloquent, but there is a confusion and wildness about its magnificence that dazzle and distract the 'suggesting principle' of the beholder. There never was, perhaps, such a striking illustration of the old quotation, that 'obscurity is the usual result of laborious efforts to be explicit. Dr. Brown attempts too much, and therefore often fails altogether. He is too minute, he crowds so many topics and circumstances into the map which he gives of his mind or ratiocination that we can sometimes at least perceive nothing distinctly. He is not content with the most important points of a view or steps of a process; he leaves nothing to the mind of the reader or to the exercise of the suggesting principle—he overwhelms it with circumstances of the minutest and fullest possible information. He is as lavishly circumstantial with the metaphysical enquirer as Mrs. Quickly with Sir John Falstaff, who would not only not suffer the worthy knight to forget any thing but would not suffer him to remember any thing of his own accord.

Dr. Brown's lectures, might however be modified and condensed into the most useful and popular metaphysical book ever given to the world. As they now stand, we fear they will not be very popular, and there will be some danger of subsequent moral professors marring and spoiling all, as Locke did the intellectual philosophy of old Hobbes.

Much of the evil we have to complain of is doubtless, ascribable to the hurried manner in which (to use a sort of cant but significant phrase) the lectures were got up, for they cannot be said to have been prepared for delivery, much less for publication. Almost every one of them, it appears, was written at the urgent call of necessity; or, as we usually say, on the spur of the moment, in the short space of a few hours on the night, or morning even, immediately pre-

ceding the reading of it to the moral philosophy class in the university of Edinburgh. This too is certainly calculated to fill us with amazement at Dr. Brown's strength of mind; yet we cannot but regret the circumstance as much as his style itself. It is possible indeed, nay probable, we suspect, that, if the lectures had not been written in breathless haste or urgent hurry, they would not have been written at all, any more than Johnson's Rambler or Rasselas. We are not sure, however, about the soundness of the opinion of the author himself, as well as of his friend and biographer, as if the excellence of the lectures were mainly ascribable to the high excitement, that is hurry, under which they were written. High excitement is indeed favorable in a well-stored mind, to torrents of discussion or bursts of eloquence; but it is not favorable to arrangement and condensation—to clearness and brevity. These all-important qualities of metaphysical compositions require cool judgment, 'waiting for thought' (to which Newton ascribes so much of his merit as a physical philosopher), and patient reflection. Probably Hobbes spent more time in condensing and lucidising one of his short chapters, than Dr. Brown did in writing several of his long lectures.

We are told, indeed, by the excellent and reverend biographer of Dr. Brown, that, when he returned afterwards to the examination of his lectures, he found that he could make very little improvement upon them, which he accounted for by the high excitement under which they were written, being peculiarly favorable to intellectual exertion or effort. That he could not find much in his own compositions, after a short lapse of time, which seemed to require alteration or amendment is not very wonderful. When we come, particularly in a sluggish state of mind, to the examination of our own compositions, we are easily satisfied; nor is it always easy to improve even very bad ones; besides, we catch anew the delightful enthusiasm under which we produced them at first—the affection with which we gazed in the first moments of their existence upon our intellectual offspring—and love, particularly parental love, is proverbially partial if not blind. Even when we have a vivid remembrance of having written something on a given subject before, though we know not well what, and are determined not to look at it, there is something of disqualification about our mind to write better upon it anew; because the mind, instead of vigorously applying to the subject is wandering or hankering after its former production. If we may be allowed to reclaim for a moment our old multitude of faculties (and really it is hard to do without them, the loss of them will deprive us of much 'revelry and ease'), we would compare them to a long team drawing tandem-wise. The first horse is genius, the second imagination, the third memory, the fourth judgment, the fifth reason, and so on to the end of the whole series. If they be all well trained and in good condition, and draw one way, the whole intellectual machine will move forwards more or less surely and steadily in the right direction; but if any of them be restive or refractory, or draw awry—if, for instance, memory be always struggling to escape, or flying to one side after something it has enjoyed before, and that it is still very fond of, it is evident the team cannot advance—the whole intellectual machine must either remain stationary or be tumbled upside down. It is somewhat after this ludicrous and absurd image of the mind and its faculties, when we do not apply with all our might to intellectual subjects which we have already discussed. It is a difficult task to decompose and recompose anew our own compositions. If it were not so, how could Dr. Brown yield himself tamely up to an idle theory about the wonder-working intellectual power of high excitement? How could he imagine that he could find little or nothing to require alteration, or to admit of improvement, in lectures written in the hurry of a few hours. Might he not (especially if he contemplated publication) have lopped off a thousand repetitions and redundancies? Might he not have improved a thousand passages by reducing them to a simpler, and clearer, and more tangible form? Might he not have compressed four volumes into two?

We will put a sort of ad hominem case to the reverend biographer of Dr. Brown, merely for his convincement; and we take it for granted that his phrenology has nothing to do with the question. We doubt not that he has two sorts of preparation for the pulpit. Sometimes he chooses his subject early, he feels deep interest in it, he wishes to do it full justice, and gives himself full time for the purpose; at other times he drives, as we say, the business of preparation off to the last; and, when he must delay it no longer, falls to work with all his might on Saturday evening, and writes doggedly, as Johnson expresses it, or under a high degree of excitement, according to Dr. Brown. Perhaps if he were to re-examine, after some lapse of time, a production of the last sort, he might find very little in it that he could alter or improve; but which of the two descriptions of preparation for the pulpit would he coolly and deliberately send to the press? But we have, perhaps, dwelt too long on the topic, though it is quite as important as any abstract or metaphysical discussion to correct an unsound opinion respecting the high excitement of breathless hurry, as favorable to intellectual effort or exertion not only in rhetorical, but even in metaphysical productions.

Though we have insisted so much on the objectionable character of Dr. Brown's general style, the reader must not suppose that he could not write well, or express himself clearly, concisely, and forcibly. Many very admirable passages, in every view of them, might be extracted from his lectures, in addition to some that we have given. He almost always writes like a man of thoughts rather than of words, and fully conscious that he had abundance of intellectual treasure to draw upon, and on which he might safely rely for effect. There is little or nothing of elegant verbiage or pompous grandiloquence about him. He will bear an advantageous comparison in this respect with even professor Playfair, who appears in all the simplicity, and dignity, and native grandeur, of a true philosopher. He does occasionally employ such ex-

pressions as philosophy of the mind, science of mind, phenomena of mind, laws of mind, &c.; but he evidently cared little for them, and would have been willing to do without them, and he was careful to explain how much or rather how little is meant by them. He did not ring changes upon them, or constantly repeat them in an eternal circle. There was nothing of philosophic cant or affectation about Dr. Brown. When, indeed, a general habit of grandiloquence is once established, as it has been with us as well as with the French, something of it is absolutely necessary to command attention, and even to convey meaning. When 'all the world is a stage, and all the men and women merely players,' we cannot perform our part without something of dramatic artifice.

But we must come to a conclusion by very briefly attempting an estimate of the amount and value of metaphysical knowledge.

It is sufficiently evident, from what has been already advanced, that if there be any thing that deserves the name of a science or philosophy of mind, it must henceforth be 'put on a footing almost entirely new,' as Hume expressed himself on the subject. The science of mind, as propounded by Dr. Reid and his illustrious pupil, instead of progressing onward ad infinitum towards infinitesimal perfection, has been wholly overthrown. It has been as completely subverted as the dynasty of the Stuarts. There has been a revolution effected in the philosophy of mind far more radical and entire than the political revolution brought in with William and Mary 'of glorious memory.' Whether it shall be of permanent stability, and its results of a progressively beneficial kind on the knowledge, and wisdom, and happiness of human beings—whether it shall accelerate the march of intellect, and its author shall be pronounced the immortal Brown, and the father of the true, experimental, inductive science of man, by a grateful and applauding posterity, is more than we dare venture to predict. Yet we think his memory will wear well, and that it has something imperishable about it. Indeed his doctrine of human nature is, we conceive, the only one since that of Hobbes (upon which it is certainly a decided improvement, as Locke's Essay and Hartley's Theory of Man were as decided deteriorations) which has any fair pretension to be considered a true statement of accurate analysis. There is much in Dr. Brown's lectures, to minds in unison with our own, that may be truly called the feast of reason and the flow of soul; nor are we wholly faithless or hopeless as to beneficial results on all kinds of philosophies, high and low, great and small. But after all, if we were closely pressed to state, in the fewest possible words, the sum total or actual amount of positive good, or of the intellectual benefaction conferred on the world by the extraordinary analytical genius of Dr. Brown, we should be somewhat perplexed. The good is of a negative rather than a positive kind. He has done much to disabuse our poor understandings, and the man that does that is a benefactor and a reformer, worthy of ranking with Martin Luther and John Knox. He who successfully detects the absurdity, and exposes the folly, of a vain and deceitful philosophy, deserves to be held in grateful remembrance. It is at least something to place us in that intellectual condition in which we might have been if such men as Aristotle had never existed, and to prevail upon our busy, meddling minds 'to stop when at the utmost extent of their tether,' as good Mr. Locke says, 'and to sit down in a quiet ignorance of those things which are found to be beyond the reach of our capacities,' without adding to all the other disquiets of this imperfect state, by torturing our frail intellects, and heating our unruly passions, with such entities and quiddities as those of the doctrines and jargon of the schoolmen.

We are not easily satisfied, however, with negative qualities in the philosophy of mind; if an old venerable pile of intellectual incumbrance and nuisance be removed, we would straightway have something large, and stately, and imposing, erected in the room of it, even if the new erection should prove nearly as much of an obstruction, incumbrance, and nuisance, as the old one. This is the danger here—instead of reforming the reformation of Dr. Brown, we have no doubt that vigorous efforts will be made by moral professors to graft upon it the old notions, or to bring it back again to something of decent conformity with the splendor and pomp of the very system which was renounced and abandoned on account of its absurdities and impostures.

We may talk largely and loftily about our philosophy of the mind, but the mind has an occult philosophy or way of its own, that mocks our experimental and inductive researches and analytic processes. The whole of the intellectual science, as Hobbes, and Descartes, and Malebranche, and others long ago said, and as no one who reflects for a moment can dispute, must rest upon consciousness; but consciousness is a sandy foundation, soon shaken. It is so shifty and shadowy, that to attempt to rest much upon it is almost like building castles in the air. Indeed how shall we proceed to bring different intellectual philosophers to agree either about what it is, or what is its testimony? For nothing can be more opposite and conflicting than their doctrines concerning both. There is abundant concord between the consciousness of Dr. Brown and our own, and therefore we think his doctrine the true one; but, if a disciple of Kant or of Dr. Reid were to choose to dispute the matter with us, it would be hopeless, or rather absurd, to attempt mutual convincement and agreement. He sets up his consciousness against ours, and we set up our consciousness against his; and there we are without a single particle of intellectual data in common to start with about the science of the mind.

As it is with the foundation itself of the whole science, so it is with all the intellectual phenomena, which according to Condillac are nothing whatever but the ghosts of departed sensations; and, though we think the French philosopher decidedly wrong here, yet there is something like the evidence of analogy about the notion too; for we might as well attempt to conjure up spirits

from the vasty deep as hope to will up any of the intellectual phenomena at pleasure. We might as well expect to put the ghost of Richard III. upon the rack to make it confess any facts respecting his nephews, as attempt to submit any of the intellectual phenomena to the experimentum crucis to make them give sure and faithful testimony concerning true and false philosophies of the mind. The mental phenomena indeed are not only a shadowy but a shy race of entities, as skilful and persevering in flight as the old Parthians; and 'retire the more the more we press.'

We may indeed get a sly peep of them occasionally, as of our own shadow over our shoulder when walking along by moon-light. But, if we turn directly round upon them, they instantly run off, and it is of no use whatever to run after them. It is as impossible to seize them and make them our prisoners, for permanent data or intellectual dissection, as to share in the deliberations of a tribe of fairies when assembled, it may be, in some adjoining field or wood under the light of the same moon to discuss metaphysical or political questions of the gravest importance. We only yield to the suggesting principle in remarking that the mental phenomena are often most vivid and strongly marked or most powerfully active in the dead hour of night when we are fast asleep; and according to Hobbes these nightly vigils or operations of the mental phenomena commonly called dreams (whether from dormio to sleep, or drama we are not sure), are the prototypes of all the mythological personages of all ages and countries, or the true and original ghosts and goblins, fairies and brownies, of all the races and tribes of men. There is some show of plausibility about this notion of the old philosopher, but what we meant to remark was the difficulty of managing and dissecting the mental phenomena, or of dealing with them in any way whatever. Many of our dreams seem at first sight to have made such a deep and lasting impression as to have become a part of our mental identity; and as that we shall have no trouble with them, any more than with our identity itself, but may analyse them at our leisure. But we are scarcely wide awake and ready for work when the subjects, on which we meant to operate for the purpose of making further discoveries in the anatomy or physiology of the mind, have vanished away; and we have the mortification as intellectual physiologists of finding that all was but the 'baseless fabric of a vision that leaves not even a wreck behind.' But enough; we only meant to abate the pride and pretension of intellectual philosophy, and to chasten and subdue its grandiloquence respecting mental data, phenomena, well ascertained facts, experimental researches, inductive reasonings, &c. &c., in the science of mind. Indeed, how any man in his sober senses, consciousness, and reflection, should seriously write about the subject in the manner Mr. Stewart does, is to us one of the most wonderful phenomena in the whole range of our poor limited observation.

Dr. Brown has done much, as already intimated, because he has simplified metaphysical matters very considerably. He has nullified much mystical jargon and visionary reasoning. He has swept away the whole multitude of mental powers and faculties created or conjured up by Dr. Reid out of the vasty deep of his mere imagination. He has reduced all that we know about the operations of the mind to simple and relative suggestion. And this seems as satisfactory an account of the matter as can be given. It is not wonderful that what is usually called (in consequence of Locke's having so termed what had been pointed out to him by Hobbes) association of ideas, should have been much philosophised about; for it is so obviously connected with consciousness, and so strikingly presented in a thousand different ways to our observation and reflection, that it is hardly possible to conceive than any human being should be so dull as not to be aware of it. Probably too the most illiterate peasant knows nearly if not quite as much about the matter as the profoundest philosopher. The chief, if not only difference between the two is, that the peasant never thought of philosophising about it as if he had made a grand discovery in the science of mind unknown to all the world beside; and, if he were to think of putting forth his thoughts concerning it, he would not be able to express them in all the pomp and circumstance of philosophic language. The following couplet of some poor poetaster was received into the mind of the writer of this paper at such an early period of life that he has no remembrance of its reception; it may therefore be in some sense considered older as a part or parcel of his mind than his very mental identity itself. Indeed he could almost fancy it to be innate, so completely unconscious is he of its intromission. It implies, however, the principle of suggestion or association as fully as any statement of Hobbes, Locke, Hartley, Hume, or Brown. Nor can he remember a time when he was ignorant of what it implies, or when he was not aware of the principle. The miserable couplet referred to is,

Dumbarton drum beats bonny O,
It minds me of my Jonny O.

This might be expressed or supposed to be expressed by an affectionate mother, whose son had left her to 'follow the drum,' as Burns expresses it; or more probably by some love-sick maid the object of whose affections (not good for much perhaps) had left her all forlorn to go and fight for his king and country. But, whatever were the occasion and the circumstances of the said couplet, the suggesting or associating principle is fully implied. Indeed the difficulty would be to find any kind of composition in which it is not implied. Instances almost innumerable might be presented to show that the least informed and philosophic of men are aware of the principle, and avail themselves of it too for practical purposes as much as if Dr. Hartley had lectured to them for a whole year upon the subject. When for instance the plain honest tradesman who wishes not to forget some one thing which is to be attended to, after some short space of time, ties one knot on the corner of his pocket hankerchief, or if he wishes to make two memorandums upon it ties two knots, what is he doing but practically philosophising (not the worst kind of philosophy

after all) upon the suggesting principle or association of ideas?

It may be thought, however, that the true science or philosophy of the mind, must be of vast importance for theorising this grand principle of our mental constitution into the greatest possible availableness for useful purposes and application, so as to promote knowledge and wisdom, and virtue, and happiness. We should be glad to know what it has done or what it can do in this way. Having some portion of parental solicitude, we turned lately with considerable intensity of desire to the article Education in the Supplement to the Encyclopædia Britannica, which we supposed must have been written by some great intellectual philosopher or other. But alas! when we arrived at the end of the whole matter it was with the mortification of finding that the title of the last chapter of Rasselas might have been an appropriate close. 'The conclusion in which nothing is concluded.' We found indeed that the writer belonged to neither the German nor Scottish school of metaphysics, that he was a great admirer of Locke, Hartley, Condillac, Helvetius, and somewhat partial to Cabanus, that he was probably a materialist and antireligionist, but that was about the amount of discovery and conjecture. A few tritical remarks in reference to the suggesting or associating principle, such as almost any well-informed tradesman, in the present intellectual state of society, could make, were all that could be found answering to the title of the article. Surely society does not now require to be told by intellectual philosophers that it is wrong to associate the idea of ghosts and goblins with darkness in the minds of children; or the idea of merit with a fine coat or splendid mansion. This is professedly an age of improvement, and we think it is not all mere talk; but we must yet draw upon hope rather than fruition. We hope that the science or philosophy of political economy, of medicine or the healing art, of agriculture, of education, and all the other sciences and philosophies any way connected with the being and well-being of men, will rapidly progress to a state of the highest perfection; but we are afraid that the science of man himself, or the philosophy of mind, will not assist much in the simultaneous movements of progression so devoutly to be wished.

There is one topic more to which we must devote a few remarks. Is there a necessary connexion between metaphysics, or as termed by Mr. Stewart the philosophy of the mind, and religion? According to that author's representations, the philosophy of the mind is the foundation of, or, at least, it is necessary to natural religion; which again is the necessary foundation of revealed religion. We have no doubt as to the goodness of his intentions in this matter, but we have considerable doubt as to the soundness of his judgment. And we fear that he, and Dr. Reid, and Dr. Beattie, have done no small disservice to the very cause which they intended to support; and for the support of which indeed their system of metaphysics was taken up: a most unfortunate circumstance too, for that cause, as distrust and suspicion are almost sure to be excited in inquisitive minds, when a set of principles, or a theory, is assumed for an obvious or avowed purpose. It is generally believed that there is a considerable portion of scepticism or disbelief as to religion, to be found among the highest classes of intellectual men in Scotland, and particularly in the Scottish capital. We do not wonder at the fact, and we conceive that, though not wholly ascribable to the Scottish metaphysics, yet they must (like those of Leibnitz and after him those of Kant in Germany) have had considerable influence. But without entering into the general merits of the Scottish metaphysicians who arrayed themselves against Hume, as to their ability or inability to contend with such an opponent, let us consider the natural tendency of their mode of proceeding. They adopt a certain set of metaphysical notions in support of natural religion, which natural religion is considered necessary to revealed religion. The one is the superstructure, the other is the foundation. Of course the superstructure requires only a secondary and very subordinate care or concern. All the energies of the guardians of religion are to be directed to the preserving of the foundation secure and entire. A certain set of metaphysical notions are thought to be necessary for this purpose, and therefore they are adopted.—Ultimate principles of our nature are created ad libitum; powers and faculties are conferred upon the human mind, almost without number; for it seemed the more of them the better, and the mightier the entrenchments and bulwarks thrown around that sole foundation of all that is great and good, natural religion. Dr. Reid went on creating powers and faculties for the human mind, and arranging them in due order, giving intimations too that all the powers and faculties were not conjured up yet, and that only a sample of them was published. But his grand achievment was the overthrow of the ideal system; and, having ceased from all his metaphysical labors, his illustrious pupil commenced his career as author of the philosophy of the mind, and nothing almost was heard of but experimental researches and inductive reasonings concerning mental data, and phenomena, and many other magnificent entities. Many were dazzled and delighted with all this success and triumph, and renown of the common-sense or Scottish metaphysics, which seemed to have put scepticism and infidelity to flight. Meanwhile, among the more reflecting deep-searching few, some laughed and others grieved, according as they were well or ill affected to real religion—that religion which is not in word only but in deed and in truth.

When Mr. Stewart retires from the chair of moral philosophy, Dr. Brown succeeds him, and with a metaphysical mastery of the highest order he overthrows all the philosophy of the mind set up in Scotland by Dr. Reid and his illustrious pupil. What conclusion would many be apt to come to who have observed all this? They would certainly be ready to argue that religion natural or revealed can stand no longer; and no doubt the representations given by Dr. Reid and Mr. Stewart of their true theory of the mind are but too much calculated to produce that opinion. Hence it is that injudicious friends are often

more prejudicial to a good cause than avowed enemies. We cannot dwell longer on the subject here. We merely add that in our humble judgment the doctrines of professor Brown bear an infinitely more favorable aspect to true religion and morality, and human well-being, than those of professor Stewart.

METAPLASM, *n. s.* Lat. *metaplasmus*; of Gr. μετα, and πλασσω, fingo, in grammar, a change made in a word, by adding, retrenching, or altering a letter or syllable.

METAPONTIUM, or METAPONTUM, in ancient geography, a town of Lucania, on the Sinus Tarentinus, west of Tarentum; built by the Pylians, who returned from Troy.—Mela; where Pythagoras is said to have taught in the time of Servius Tullius.—Livy; and the people pretended to show, in a temple of Minerva, the tools with which Epeus built the wooden horse of Troy.—Justin. It is now a tower, called Torre di Mare, in the Basilicata

METASTASIS, *n. s.* Gr. μεταστάσις. Translation or removal; applied particularly to diseases.

His disease was a dangerous asthma; the cause a *metastasis*, or translation of tartarous humours from his joints to his lungs. *Harvey on Consumptions.*

It is scarcely necessary here to point out examples of the *metastasis* of diseases, which are universally recognised · such are the severe attacks of disorders in the stomach, when the inflammatory gout suddenly disappears from the extremities; the occurrence of diarrhœa or dysentery, upon the sudden retrocession of the measles, or other extensive eruption of the skin; the appearance of epileptic convulsions upon the cessation of the hæmorrhoidal, or other habitual discharge; the inflammation of the testes in men, or of the mammæ in women, which ensues, when that of the parotid glands in the disease called mumps, suddenly disappears; and other cases of a similar nature. *Dr. A. Rees.*

METASTASIO (Abbé Peter Bonaventure), whose real name was Trapassi, was born in Rome in 1698. His talent for poetry was first unfolded by reading Tasso; and he began to compose verses at ten years of age, which procured him the patronage of the celebrated Gravina. He was only fourteen when he composed his tragedy entitled Il Giustino; in which he appears too close and scrupulous an imitator of the Grecian drama. He lost his patron in 1717; who left him his heir, 'as being a young man of the most promising abilities.' Metastasio, at the age of nineteen, being, by this inheritance, superior to those wants which repress the exertions of genius, and to which men of abilities are too often subject, gave full scope to his inclination for poetry. He began his dramatic career with the Didonne Abandonnata, which was acted at Naples in 1724; the music composed by Sarro. He soon acquired such celebrity, that, in 1729, he was invited to Vienna by Charles VI.; who appointed him imperial poet, with a pension of 4000 florins. From that time some of his works were presented at every court festival. The courts of Vienna and Madrid vied with each other in the presents which they conferred upon him. This favorite of kings and of the muses was of a cheerful temper, and was exceedingly temperate; to this he was probably indebted for uninterrupted health and the entire possession of his senses to old age. He was also extremely regular in his diet, sleep, &c. He had even his stated hours for versification; to which he scrupulously adhered, without waiting for the moment of poetical enthusiasm. He was attacked by a fever on the 2d of April, 1782, and died on the 12th, aged eighty-four.' He left about 150,000 florins. He composed a great number of tragic operas, and several small dramatic pieces which have been set to music. Editions of them were printed in 4to. 8vo. and 12mo.; and M. Richelet published a translation of them into French, in 12 vols. 12mo.

METATAR'SUS, *n. s.* }
METATAR'SAL, *adj.* } Gr. μέτα and ταρσός, the TARSUS, which see. The middle of the foot; belonging to this part of the foot.

The conjunction is called synarthrosis, as in the joining the tarsus to the *metatarsus*. *Wiseman.*

The bones of the toes, and part only of the *metatarsal* bones, may be carious; in which case cut off only so much of the foot as is disordered. *Sharp's Surgery.*

METATARSUS. See ANATOMY.

METARO, a river of Italy, in the marquisate of Ancona, which runs into the Adriatic near Ancona. It gave name to one of the eight departments into which the Papal dominions were divided, when they were revolutionised in March 1798, by the French, and erected into the short-lived Roman republic.

METATHE'SIS. Gr. μεταθεσις, of μετα, trans, and θεσις, position. Transposition; a grammatical figure, whereby letters or syllables of a word are transposed, or shifted from their natural situation. Metathesis is also used by medical writers for a change of place in such humors, or other diseased parts, as cannot be absolutely removed or sent off. Thus a metathesis of a cataract is a depression, so that it no longer shuts out the light.

METE, *v. a.* }
ME'TER, *n. s.* }
METE'WAND, }
METE'YARD. } Sax. mæthan; Goth. and Swed. *meta*; Belg. *meten*; Lat. *metior*; Gr. μετρέω; Heb. מדד. To measure; reduce to measure; give out or apportion by measure: a meter is a measurer: mete-wand and mete yard, instruments of measurement.

Ye shall do no unrighteousness in meteyard, weight, or measure. *Lev.* xix. 35.

I will divide Shechem, and *mete* out the valley of Succoth. *Psalms.*

With what measure ye *mete*, it shall be measured to you again. *Matt.* vii. 2.

A true touchstone, a sure *metewand*, lieth before their eyes. *Ascham's Schoolmaster.*

Though you many ways pursue
To find their length, you'll never *mete* the true.
But thus; take all that space the sun
Metes out, when every daily round is run. *Creech.*

To measure any distance by a line, apply some known measure wherewith to *mete* it. *Holder.*

METELLUS, the surname of the family of the Cæcilii at Rome, the most celebrated of whom were, 1. A general who defeated the Achæans, took Thebes, and invaded Macedonia, &c. 2. Q. Cæcilius, who rendered himself illustrious by his successes against Jugurtha, king of Numidia, from which he was surnamed Numidicus. 3. Q. Cæcilius, who was pontifex maximus, and saved from the flames the palladium, when Vesta's temple was on fire. He lost his sight and one of his arms in the action; and the senate, to reward his zeal and piety, permitted him always to be drawn to the senate-house in a chariot, an honor which no one had ever before enjoyed. He also gained a great victory over the Carthaginians. 4. Q. Cæcilius Celer, who distinguished himself by his spirited exertions against Catiline. He married the sister of Clodius, who disgraced herself by her lasciviousness. He died A. A. C. 57. He was greatly lamented by Cicero, as one of the most faithful and valuable friends. 5. L. Cæcilius, a tribune in the civil wars of Cæsar and Pompey. He favored the cause of Pompey, and opposed Cæsar when he entered Rome with a victorious army. He refused to open the gates of Saturn's temple, in which were deposited great treasures; upon which they were broken open by Cæsar, and Metellus retired. 6. Q. Cæcilius, a warlike general, who conquered Crete and Macedonia, and was surnamed Macedonicus. 7-10. He had four sons, of whom three were consuls, and the other obtained a triumph, all during their father's lifetime. Cimber, a conspirator against Cæsar, who gave the signal to murder him in the senate-house.

METEMPSYCHO'SIS, *n. s.* } Gr. μετεμψύχωσις, The
METEMPSYCHOSE', *v. a.* } transmigration of souls from body to body. See below.

The souls of usurers after their death, Lucian affirms to be *metempsychosed*, or translated into the bodies of asses, and there remain certain years, for poor men to take their pennyworth out of their bones.
Peacham on Blazoning.

From the opinion of *metempsychosis*, or transmigration of the souls of men into the bodies of beasts, most suitable unto their human condition, after his death Orpheus the musician became a swan.
Browne's Vulgar Errours.

METEMPSYCHOSIS is formed of μετα, beyond and εμψυχω, I animate. Pythagoras and his followers held, that after death men's souls passed into other bodies, of this or that kind, according to the life they had led. If they had been vicious, they were imprisoned in the bodies of miserable beasts, there to do penance for several ages; at the expiration whereof they returned again to animate men. But, if they lived virtuously, some happier brute, or a human creature, was to be their lot. Pythagoras is said by some to have borrowed the notion of a metempsychosis from the Egyptians; by others from the ancient Brachmans. It is still retained among the idolaters of India and China; and makes the principal foundation of their religion. So extremely are they bigoted to it, that they not only forbear eating any thing that has life, but many of them even refuse to defend themselves from wild beasts. They burn no wood, lest some little animalcule should be in it; and will redeem from the hands of strangers any animals that they find ready to be kiiled. See PYTHAGORAS.

METEMPTOSIS, from μετα, after, and πιπτω, I fall, a term in chronology, expressing the solar equation necessary to prevent the new moon from happening a day too late; by which it stands contradistinguished from Proemptosis, which signifies the lunar equation necessary to prevent the new moon from happening too soon. The new moon's running a little backwards, that is, coming a day too soon at the end of 312 years and a half; by the proemptosis, a day is added every 300 years, and another every 2400 years: on the other hand, by the metemptosis, a bissextile is suppressed each 134 years; that is, three times in 400 years. These alterations are never made but at the end of each century; that period rendering the practice of the calendar easy. There are three rules for making this addition or suppression of the bissextile day, and for changing the index of the epacts. 1. When there is a metemptosis without a proemptosis, the next following, or lower index, must be taken. 2. When there is a proemptosis without a metemptosis, the next preceding or superior index is to be taken. 3. When there are both a metemptosis and a proemptosis, or when there is neither the one nor the other, the same index is preferred. Thus, in 1600, we had D: in 1700, by reason of the metemptosis, C was taken: in 1800 there were both a proemptosis and metemptosis; so the same index was retained. In 1900 there will be a metemptosis again, when B will be taken; which will be preserved in 2000, because there will then be neither the one nor the other. This is as far as we need to compute for it: but Clavius has calculated a cycle of 301,800 years; at the end of which period the same indices return in the same order. See EPACT

METEOROLOGY.

METEOR, *n. s.* } Fr. *meteore*; Gr.
METEOR'ICAL, *adj.* } μετεωρα, à μετεωρος,
METEOROLOG'ICAL, } high. Any light and
METEOROL'OGIST, *n. s.* } fleeting aërial body; a
METEOROL'OGY, } luminous body of this
METE'OROUS, *adj.* } kind: meteorical, resembling a meteor: meteorological is, relating to the doctrine of meteors: a meteorologist, he who studies or is a proficient in that doctrine: meteorology, the science which treats of it, see below: meteorous is, having the nature of a meteor.

Looked he or red, or pale, or sad, or merrily?
What observation madest thou in this case,
Of his heart's *meteors* tilting in his face?
Shakspeare.

She began to cast with herself from what coast this blazing star must rise upon the horizon of Ireland; for there had the like *meteor* strong influence before.
Bacon's Henry VII.

These burning fits but *meteors* be,
Whose matter in thee soon is spent:
Thy beauty, and all parts which are in thee,
Are an unchangeable firmament. *Donne.*

It is no otherwise in the firmament of the church: how many have there been, that have seemed eternally fixed in that high sphere, which have proved no other than base *meteors*, gilded with fair beams! they appeared stars; their substance was but slime. *Bp. Hall.*

In a third, I see a resemblance of that *meteorical* light, which appears in moorish places, that seems fire, but is nothing but a slimy glittering exhalation. *Id.*

The *meteorologists* observe, that, amongst the four elements which are the ingredients of all sublunary creatures, there is a notable correspondency. *Howel's Vocal Forest.*

From o'er the hill
To their first station, all in bright array,
The cherubim descended, on the ground
Gliding *meteorous*, as evening mist
Risen from a river. *Milton's Paradise Lost.*

In animals we deny not a natural *meteorology*, or innate presentation of wind and weather. *Browne.*

Others are considerable in *meteorological* divinity. *Id.*

Why was I raised the *meteor* of the world,
Hung in the skies, and blazing as I travelled,
Till all my fires were spent; and then cast downward
To be trod out by Cæsar? *Dryden. All for Love.*

O poet, thou hadst been discreeter,
Hanging the monarch's hat so high,
If thou hadst dubbed thy star a *meteor*,
Which did but blaze, and rove, and die. *Prior.*

METEOROLOGY, from Gr. *μετεωρος*, high; or rather from *μετα*, denoting change of place, and *αειρω*, to lift up (it is worth remarking also that *μετεωροι* is often used by the Greek writers, both sacred and profane, to signify being agitated or tossed about, as a ship at sea), is that science which professes to treat of the general phenomena of the atmosphere; and has by some writers been considered as embracing its entire composition, changes, and appearances. Particular classes of those appearances which strike the eye were long emphatically called *meteors*, Gr. *μετεωρα*, Lat. *impressiones*, as making signs or impressions on the air; and gave their name to the whole doctrine of aërial phenomena, which has hence been treated as one and the same throughout. It is quite evident that we might as reasonably suppose every doctrine that can be expressed or impressed upon paper as one and the same.

This is therefore one of those terms of science, having their origin partly in the observations and apprehensions of the vulgar, and partly in the too early attempt to generalise that marks a particular stage in the progress of all the sciences, which it is the tendency of experiment and of a maturer state of knowledge to explode. Certainly there is *no science* of meteorology if there be any distinction worth retaining in the sciences; and if some of the most brilliant discoveries of modern science are worth any thing: what has been often thus denominated has been demonstrated to belong to ELECTRICITY, to MAGNETISM, or ELECTRO-MAGNETISM, in great part; and still more to CHEMISTRY, to COMBUSTION, to OPTICS or to PNEUMATICS; to the laws of VISION, or to the doctrine of LIGHT and HEAT. It is impossible indeed to treat of these topics scientifically, without exhibiting the causes and laws of almost every phenomenon which meteorology has been thought to include; and it will eventually, we have no doubt, be felt as absurd to look for an account of these widely different operations of nature under such a general head, because they appear in or through the medium of the atmosphere, as under the article ASTRONOMY itself, because a large portion of them have been long termed 'falling stars.'

Yet the history of what has been called meteorology has some points of great interest about it; and like alchemy and judicial astrology it will be found to have led forward some noble spirits to distinguished and most important attainments in science. For this reason we shall give a brief historical account of its progress, and present state; the best modern instruments employed in meteorological observations; and a list of the singular productions called meteorolites, or meteoric stones.

SECT. I. PROGRESS OF OPINION ON THE COMPOSITION OF THE ATMOSPHERE.

1. The *atmosphere* was so denominated by the Greeks (*ατμος*, a vapor, and *σφαιρα*) from the quantity of vapor combined in it. Aristotle, it is well known, considered it a species of element occupying a middle place between fire and water: mingled with dry exhalations he states it to produce thunder, lightning, and wind; and with moist exhalations, rain, snow, and hail. The ancients seem to have had a general belief that atmospheric air was a constituent principle of other bodies, and that they were mutually convertible into each other: thus Lucretius, as translated by Good, says

All that pours profuse
From things, perpetual, the vast ocean joins
Of air sublime; which if to things again
Paid not, thus balancing the loss sustained,
All into air would dissipate and die.
Hence, born from things, to things air still returns
Ceaseless, as prove their fluctuating forms.

To the physical properties of the atmosphere, however, the actual observations of the ancients were confined: its chemical and mechanical properties cannot be said to have been the subjects of experiment until the beginning of the seventeenth century. Galileo led the way by pointing out its weight, a subject to which Torricelli and Pascal directed their attention: its density and elasticity were ascertained by the Florentine academicians, and still more accurately by Mr. Boyle, who fully demonstrated its essential connexion with combustion, the wants of animal life, &c. Together with Hooke, Newton, and Durham, he also considered its relation t sound, to light, and to electricity. Sir Isaac Newton explained the effect produced upon it by moisture; and on this foundation Halley began to explain the ehanges in its weight as indicated by the barometer. But the former had some curious opinions as to the origin of the atmosphere: as he supposed the planets generally, to

be influenced by comets; so from the tails of the latter he thought that some of the finer parts of our atmosphere were produced. He even supposed, that from these bodies a quantity of water, imagined to be wasted in the various operations of nature, might be supplied.

Mr. Boyle, and his contemporaries, put it beyond doubt that the atmosphere contained two distinct substances. 1. An elastic fluid distinguished by the name of air. 2. Water in a state of vapor. Besides these two bodies, it was supposed that the atmosphere contained a great variety of other substances, which were continually mixing with it from the earth, and which often altered its properties, and rendered it noxious or fatal. But to Mayow, in particular, who succeeded Boyle, we may certainly trace the nucleus of all the great modern discoveries in the analysis of atmospheric air. He rejected the use of the air-pump, and made choice of glass jars, inverted in water, as the best method of confining gases. From the facts discovered by Boyle, he argues, that, since a lighted candle is extinguished much sooner in an exhausted receiver than in the same when filled with air, there must be something contained in the atmosphere necessary to the continuance of flame; and that a candle, in confined air, is not suffocated by its own fuliginous exhalations, but dies away for want of an aërial pabulum. The necessity of air to combustion is proved, says he, from the impossibility of kindling a combustible body in vacuo by the concentrated solar rays, or by any other method. Having established this position, he proceeds to infer that it is not the whole air but only its more active particles, that are capable of supporting flame, because a candle goes out in confined air, while yet the greatest part of the electric fluid remains unconsumed. Also, since sulphur, when mixed with nitre, becomes capable of inflammation in vacuo, or even under water, it follows that nitre and atmospherical air contain some substance in common, which he calls fire-air particles (particulæ igneo-aereæ). He next determined the analogy between flame and animal life; and showed, that each depended for their continuance on a supply of fire-air particles: that there was an actual consumption of air in combustion and respiration he proved, by the rise of water in the jars in which a live animal or a lighted candle was enclosed; and that the loss of bulk was owing to the abstraction of fire-air, appeared from the inability of the residue to support animal life. He inferred, also, that the fire-air particles were the heaviest part of atmospheric air, because, if two mice or two candles were confined in a tall cylindrical jar, inverted in water, so as that one should be near the upper part of the vessel, and the other at the bottom, the upper one, whether a candle or animal, would be extinguished some time before the lower one. With regard to the proportion of fire-air in the atmosphere, he only observed, that air rendered unfit for combustion by the breathing of an animal, lost about one-fourteenth of its bulk; at the same time remarking, that there was probably only a part of the fire-air consumed: he afterwards, indeed, found that the solution of iron in aquafortis occasioned a diminution of about 25 per cent. in atmospheric air; but though, in this case he produced nitrous gas, and thus abstracted the oxygen of the atmosphere, yet, as he himself draws no conclusions from it, we should rather consider this as an accident than a discovery. Mayow never obtained the fire-air of the atmosphere in a separate state, and therefore was unable to confirm his analysis of atmospheric air by the synthetical proof; nevertheless, he was warranted by a very high probability in affirming that the atmosphere consisted of two kinds of air, of which the igneo-aerial was in the proportion of at least one to thirteen; that it exceeded the other part in its specific gravity, and was absolutely essential to the continuance of flame and animal life. The influence, however, of the prevalent hypothesis was at that time too strong to be shaken by sober experiment; and the labors and very name of Mayow shortly sunk into oblivion, until in 1744 Dr. Priestley's discovery of what he called dephlogisticated air, accidentally revived them.

Next follow Hales, Black, Priestley, Scheele, and Lavoisier, in this department of science; but we have already detailed their labors in the article Air. The 'foul air' of Scheele is the phlogisticated air of Dr. Priestley and the azotic gas of the modern nomenclature. His empyreal air is the same with the dephlogisticated air of Priestley, or the modern oxygen gas.

Lavoisier, while Scheele was occupied with his experiments, was assiduously employed on the same subject, and was led by a different road to precisely the same conclusion. By oxidising mercury in a vessel filled with common air, and heated to the boiling point of mercury, he abstracted the greater part of its oxygen gas; and, by heating the red oxide formed, he reconverted it into mercury, and extricated a quantity of oxygen. The residuum in the first experiment possessed the properties of azotic gas; but, when the oxygen gas extricated from the mercury was added to it, the mixture assumed again the properties of common air. Hence he concluded that air is composed of azotic gas and oxygen; and from a variety of experiments he determined the proportions to be seventy-three parts of azotic gas and twenty-seven parts of oxygen gas. He stated, too, that when air is diminished by liquid sulphurets, metals, &c., the oxygen gas which is abstracted combines with the sulphurets, &c., and converts them into acids or oxides according to their respective nature.

The general composition of the atmosphere having thus become known, it became important to determine the relative quantity of oxygen in a given portion of air, which gave rise to the invention of the Eudiometer. See our article of that name.

Mr. Cavendish first brought the eudiometer to such a state of precision as to be enabled to ascertain correctly the constituents of air. His method was to put 125 measures of nitrous gas into a glass vessel, and to let up into it very slowly 100 measures of the air to be examined, agitating the vessel containing the nitrous gas during the whole time. The diminution of bulk when the process was conducted in this way was

almost uniform. The greatest was 110, the least 106·8; the mean 108·2. The variation he found to depend, not upon the air examined, but upon the state of the water in which the experiment was made. If this experiment was reversed, by letting up the nitrous gas to common air, he used 100 measures of each, and the diminution in that case was only ninety measures. This regular diminution of the bulk of all the different specimens of common air examined, induced Mr. Cavendish to conclude that the proportion between the oxygen and azote in common air does not vary. To find the absolute quantity of oxygen in air, he mixed together oxygen gas and azote in various proportions, and at last found that a mixture of ten measures of the purest oxygen which he could procure with thirty-eight measures of azote, was just as much diminished by the nitrous gas as the same bulk of common air. Hence he concluded that air is composed of ten parts by bulk of oxygen and thirty-eight of azote, which gives us for its composition per cent.

79·16 azote.
20·84 oxygen

100·00

or very nearly twenty-one per cent. of oxygen gas (Philosophical Transanctions, 1808, p. 107). Other philosophers, who did not pay Mr. Cavendish's rigid attention to precision, obtained variable results from the nitrous gas eudiometer. Most of the circumstances which occasion the variation were pointed out by Cavendish; but they seem to have escaped the observation of succeeding chemists.

Humboldt's attempt to render the eudiometer of Fontana accurate did not succeed; but Mr. Dalton explained the anomalies in a very luminous manner. According to this philosopher, oxygen gas and nitrous gas are capable of uniting in two proportions: twenty-one measures of oxygen gas uniting either with thirty-six measures of nitrous gas, or with twice 36, = 72 measures, and both of these compounds are soluble in water. If the tube be wide, a considerable portion of nitrous gas comes at once in contact with the oxygen. Hence the latter gas combines with a maximum of nitrous, especially if agitation be employed. In a narrow tube the oxygen combines with the minimum of nitrous gas, provided no agitation be employed, and the residue be poured soon into another vessel. When intermediate proportions are used, the absorption will be immediate. Mr. Dalton recommends a narrow tube; the nitrous gas is only to be in the proportion requisite to form the minimum combination; no agitation is to be employed: and, when the diminution is completed, the gas must be transferred to another tube. To 100 measures of air add about thirty-six of nitrous gas; note the diminution of bulk, and multiply it by seven-nineteenths; the product gives the bulk of oxygen in the air examined.

In order to get rid of the anomalies which had perplexed former experimenters, Sir Humphry Davy proposed to employ the nitrous gas in a different state. He caused sulphate or muriate of iron to absorb this gas to saturation, and employed the dark brown liquid thus obtained to deprive air of its oxygen. A small graduated glass tube, filled with the air to be examined, is plunged into the nitrous solution, and moved a little backwards and forwards. The whole of the oxygen is absorbed in a few minutes The state of greatest absorption ought to be marked, as the mixture afterwards emits a little gas, which would alter the result. By means of this Sir Humphry examined the air at Bristol, and found it always to contain about 0·21 of oxygen. Air sent to Dr. Beddoes from the coast of Guinea gave exactly the same result.

It appears, whatever are the varieties of this and other instruments employed, that the result is pretty uniform: they all indicate that common air consists very nearly of twenty-one parts of oxygen, and seventy-nine of azote. Gay Lussac examined air brought from the height of more than 21,000 feet above Paris, and found it precisely the same as the air at the earth's surface.

'But twenty-one cubic inches of oxygen gas,' says Dr. Thomson, 'weigh 9·14 grains, and seventy-nine inches of azote weigh 23·9686 grains; these added together amount to 31·1086 grains; which ought to be the weight of 100 inches of common air. But this is somewhat greater than the weight of 100 inches of air, according to Sir John Shuckburgh Evelyn's experiment, who found it only 31·0127 grains. The difference, however, is not great, and is probably owing to a small error in the specific gravities of the different gases. According to this estimate, 100 parts of air are composed by weight of

22·91 oxygen
77·09 azote

100·00

2. *Of the aqueous parts of the atmosphere.*—Dr. Hooke, and afterwards Dr. Halley, conceived that water may be dissolved in air in the manner that salt is held in solution by water. M. Le Roy endeavoured to confirm this in 1751, and about the same time Dr. Hamilton of Dublin espoused the same theory. Deluc afterwards suggested, that water more probably and generally exists in air in the state of vapor. But we are indebted to Mr. Dalton for the first information on the subject that can be called precise. In the Manchester Memoirs, v. p. 517, he thus states his opinions:—

(1.) It cannot be doubted, he contends, that the water which exists in air, is derived originally from the waters on the surface of the earth, which are exposed to the action of the atmosphere. Accordingly we find that water, when exposed to the air, suffers a gradual diminution of bulk, and at last disappears altogether. This diminution of the water may be owing, either to its gradual solution in air, or to its conversion into vapor. The last is the common opinion, as the phenomenon is in common language ascribed to the evaporation of the water. When water is placed in an exhausted receiver, it diminishes in bulk even more rapidly than in the open air. In this case, as no air is present, we can only ascribe the diminution

of bulk to the conversion of the water into vapor. Accordingly we find, upon examination, that the receiver is actually filled with water in the state of vapor. The presence of this vapor very soon, by its elasticity, puts an end to the evaporation of the water. Now, since water disappears equally whether air be present or not, and exactly in the same manner, it is reasonable to ascribe its disappearing in both cases to the same cause. But in the exhausted receiver it is converted into vapor. Hence it is probable that it is converted into vapor also in the open air; and, if so, it must exist in air in the state of vapor.

(2.) If the disappearing of water exposed to the open air were owing to solution, and not to evaporation, it ought certainly to disappear more rapidly when it is exposed to the action of a great quantity of air than when to a small quantity; for the quantity of any body dissolved is always proportional to the quantity of the solvent. But the very contrary is what actually takes place with respect to the water contained in the air. Saussure has proved that water evaporates much faster at great heights than at the surface of the earth, even when the temperature and the moisture of the air in both places are the same. By comparing a set of experiments made upon the Col-du-Geant, at the height of 11,275 feet above the level of the sea, with a similar set made at Geneva, 1324 feet above the level of the sea, he ascertained, that, supposing the temperature and the dryness of the air in both places the same, the quantity of water evaporated at Geneva is to that evaporated on the Col-du-Geant in the same time and same circumctances as 37 to 84, or nearly as 3 : 7. Now the air on the Col-du-Geant is about one-third rarer than at Geneva; so that the diminution of about one-third in the density of the air more than doubles the rate of evaporation. This is precisely what ought to be the case, provided the water which disappears mixes with the air in the state of vapor only; but the very contrary ought to hold, if the water disappeared in consequence of a solvent power in the air.

(3.) It has been demonstrated by Dr. Black, that vapor is water combined with a certain dose of caloric. Consequently, when water is converted into vapor, a certain portion of caloric combines with it and disappears. If, therefore, there is the same waste of caloric whenever water passes from a liquid state, and enters into the atmosphere as a component part, we have reason to conclude that it enters into the atmosphere only in the state of vapor. But it is a well-known fact, that cold is always generated during spontaneous evaporation; that is to say, that the water as it disappears carries off with it a quantity of caloric. It is well known that, when a wet body is exposed to the air, its temperature is lowered by the evaporation which takes place upon its surface. Hence, in warm countries, water is cooled by putting it into porous vessels, and exposing it to the air. The water penetrates through the vessels, evaporates from their surface, and carries off so much heat, as even in some cases to freeze the water in the vessel. Saussure observed, that the evaporation from the surface of melted snow caused it to freeze again when the temperature of the surrounding air was 4·5° above the freezing point. Dr. Black has rendered it probable that the quantity of caloric which disappears during spontaneous evaporation is as great as that which is necessary to convert water into steam. We have a right then to conclude that water, when it evaporates spontaneously, is always converted into vapor, which of course is only in that state that it enters into the atmosphere.

(4.) Mr. Dalton has demonstrated that the water which exists in air possesses precisely the same degree of elasticity that it does when in the state of a vapor in a vacuum at the same temperature. Hence it follows irresistibly that it exists in air, not in the state of water, but of an elastic fluid or vapor. We are authorised to conclude, then, that the water which exists in the atmosphere is in the state of vapor. This vapor is held in solution by the air precisely as one species of gas is by another. Hence the reason why it is so difficult to separate it, and why it is capable of undergoing a considerable degree of compression without assuming the form of a liquid.

Various attempts have been made to measure the quantity of water contained in air; but Saussure was the first who attained any thing like precision. This philosopher states, in his Hygrometrical Essays, that an English cubic foot of air, when saturated with water at the temperature of 66°, contains only about eight grains troy of that liquid, or about one-sixty-seventh of its weight. But the experiment of Mr. Dalton was susceptible of more precision. As the greatest part of the water of the atmosphere is in the state of vapor, the elasticity of which depends upon the temperature, it is obvious that this elasticity, provided it can be ascertained, must measure the quantity of vapor which exists in the atmosphere, the temperature being the same. The elasticity or force of vapor, was determined by this ingenious philosopher in the following manner, which had been originally contrived by Le Roy: he took a tall cylindrical glass jar, dry on the outside, and filled it with cold spring water fresh from the well: if dew was immediately formed on the outside, he poured the water out, let it stand the while to increase in temperature, dried the outside of the glass well with a linen cloth, and then poured the water in again. This operation was to be continued till the dew ceased to be formed, and then the temperature of the water was observed; and opposite to it in the table was found the force of vapor in the atmosphere. This experiment must be conducted in the open air, or at a window; because the air within is generally more humid than that without. Spring water is generally about 50°, and will mostly answer the purpose of the three hottest months in the year: in other seasons an artificial cold mixture is required. From Dalton's experiments it followed that the quantity of vapor in the atmosphere is variable in quantity. In the torrid zone its force seems to vary from 0·6 to one inch of mercury. In Britain it seldom amounts to 0·6, but is often as

great as 0·5 during summer. In winter it is often as low as 0·1 of an inch of mercury. Mr. Dalton supposes that the medium quantity of vapor held in solution at once in the atmosphere may amount to about one-seventieth of its bulk.

3. *Of the carbonic acid gas of the atmosphere.*—The existence of carbonic acid gas, as a constituent of the atmosphere, was observed by Dr. Black immediately after he had ascertained the nature of that fluid.

'If we expose,' says Dr. Thomson, 'a pure alkali or alkaline earth to the atmosphere, it is gradually converted into a carbonate by the absorption of carbonic acid gas. This fact, which had been long known, rendered the inference, that carbonic acid gas existed in the atmosphere, unavoidable, as soon as the difference between a pure alkali and its carbonate had been ascertained to depend upon that acid. Not only alkalies and alkaline earths absorb carbonic acid when exposed to the air, but several of the metallic oxides also. Hence the reason that we so often find the native oxides in the state of carbonates. Thus rust is always saturated with carbonic acid.

'Carbonic acid gas not only forms a constituent part of the atmosphere near the surface of the earth, but at the greatest heights which the industry of man has been able to penetrate. Saussure found it at the top of Mont Blanc, the highest point of the old continent; a point covered with eternal snow, and not exposed to the influence of vegetables or animals. Lime-water, diluted with its own weight of distilled water, formed a pellicle on its surface after an hour and three quarters exposure to the open air on that mountain; and slips of paper, moistened with pure potash, acquired the property of effervescing with acids after being exposed an hour and a half in the same place. Now this was at a height no less than 15,668 feet above the level of the sea. Humboldt has more lately ascertained the existence of this gas in air brought by Mr. Garnerin from a height not less than 4280 feet above the surface of the earth, to which height he had risen in an air-balloon. This fact is a sufficient proof that the presence of carbonic acid in air does not depend upon the vicinity of the earth. The difficulty of separating this gas from air has rendered it difficult to determine, with accuracy, the relative quantity of it in a given bulk of air. From the experiments of Humboldt, it appears to vary from 0·005 to 0·01.'

Dalton's experiments give a much smaller quantity. He found, that if a glass vessel filled with 102,400 grains of rain water be emptied in the open air, 125 grains of lime water be poured in, and the mouth then closed; by sufficient time and agitation the whole of the lime-water is just saturated with the carbonic acid which it finds in the enclosed volume of air: but 125 measures of lime-water require seventy measures of carbonic acid gas to saturate them. Hence he concludes that air contains only $\frac{1}{1400}$th of its bulk of carbonic acid. From the experiments of Mr. Cavendish, however, we learn that lime-water is not capable of entirely depriving air of its carbonic acid. A portion still remains, which can only be separated either by milk of lime, or by repeated washings with new doses of lime-water. Hence the quantity of carbonic acid in air must be greater than it was found by Mr. Dalton. The three great component parts of the atmosphere are thus exhibited by Mr. Thomson:—

98·9 air.
1·0 vapor.
0·1 carbonic acid.

This last writer notices, in addition, the presence of what he calls 'unknown bodies' in the atmosphere, or respecting which very little satisfactory is known, as we are not in possession of instruments sufficiently delicate to ascertain their presence. We can indeed detect several of them actually mixing with the air, but what becomes of them afterwards we are not able to say. Dr. Thomson thus enumerates them:—1. Hydrogen gas is said to have been found in air situated near the crater of volcanoes, and it is very possible that it may exist always in a very small proportion in the atmosphere. From the experiments of Gay Lussac and Humboldt, it appears that air does not contain so much as $\frac{1}{1000}$th parts of hydrogen. 2. Carbureted hydrogen gas is often emitted by marshes in considerable quantities during hot weather. But its presence has never been detected in air; so that in all probability it is again decomposed by some unknown process. 3. Oxygen gas is emitted by plants during the day. We shall find reason to conclude that this is in consequence of the property which plants have of absorbing and decomposing carbonic acid gas. Now, as this carbonic acid is formed at the expense of the oxygen of the atmosphere, as this oxygen is again restored to the air by the decomposition of the acid, and as the nature of atmospheric air remains unaltered, it is clear that there must be an equilibrium between these two processes; that is to say, all the carbonic acid formed by combustion must be again decomposed, and all the oxygen abstracted must be again restored. The oxygen gas, which is thus continually returning to the air, keeps its component parts always at the same ratio. 4. The smoke and other bodies which are continually carried into the air by evaporation, &c., are probably soon deposited again, and cannot, therefore, be considered, with propriety, as forming parts of the atmosphere

'But there is another set of bodies which are occasionally combined with air, and which, on account of the powerful action which they produce on the human body, have attracted a great deal of attention. These are sometimes known by the name of matters of contagion. That there is a difference between the atmosphere in different places, as far as respects its effects upon the human body, has been considered as an established point in all ages. Hence some places have been celebrated as healthy, and others avoided as pernicious to the human constitution. It is well known that in pits and mines the air is in such a state as to suffocate, almost instantaneously, those who attempt to breathe in it. Some places are haunted by peculiar diseases. It is known that those who frequent the apartments of persons ill of certain maladies are extremely

apt to catch the infection; and in prisons, and other places where crowds of people are confined together, when diseases once commence, they are wont to make dreadful havoc. In all these cases it has been supposed that a certain noxious matter is dissolved by the air, and that it is the action of this matter which produces the mischief. This noxious matter is in many cases readily distinguished by the peculiarly disagreeable smell which it communicates to the air. No doubt this matter differs according to the diseases which it communicates, and the substance from which it has originated.'

Morveau, on attempting to ascertain its nature, found the chemical tests hitherto discovered altogether insufficient for that purpose. 'He has put it beyond a doubt, however,' says Dr. Thomson, 'that the noxious matter which rises from putrid bodies is of a compound nature; and that it is destroyed together by certain agents, particularly by those gaseous bodies which readily part with their oxygen. He exposed air infected by putrid bodies to the action of various substances; and he judged of the result by the effect which these bodies had in destroying the fetid smell of the air. The following is the result of his experiments:—1. Odorous bodies, such as benzoin, aromatic plants, &c., have no effect whatever. 2. Neither have the solutions of myrrh, benzoin, &c., in alcohol, though agitated in infected air. 3. Pyroligneous acid is equally inert. 4. Gunpowder, when fired in infected air, displaces a portion of it; but what remains still retains its fetid odor. 5. Sulphuric acid has no effect; sulphureous acid weakens the odor, but does not destroy it. 6. Vinegar diminishes the odor, but its action is slow and incomplete. 7. Acetic acid acts instantly, and destroys the fetid odor of infected air completely. 8. The fumes of nitric acid, first employed by Dr. Carmichael Smith, are equally efficacious. 9. Muriatic acid gas, first pointed out as a proper agent by Morveau himself, is equally effectual. 10. But the most powerful agent is oxymuriate acid gas (chlorine), first proposed by Mr. Cruikshanks, and now employed with the greatest success in the British navy and military hospitals.'

For the more modern opinions upon the subject of the composition of the atmosphere, the reader is referred to the article AIR.

SECT. II.—OF THE WEIGHT AND PRESSURE OF THE ATMOSPHERE.

Meteorology has been largely conversant with the weight and pressure, or elasticity, of the atmosphere. It appears to be a general law of elastic fluids, that their pressure on any given surface is diminished as their bulk is increased. If, therefore, the column of mercury in the vacuum of an air-pump were sixty inches high, the air would be reduced to half its natural bulk; and, for the same reason, the pressure of a column of thirty inches of mercury in the open air will reduce any portion of air to half its bulk, since the natural pressure of the atmosphere, which is equal to that of about thirty inches of mercury, is doubled by the addition of an equal pressure. In this manner the density of the air in a diving-bell is doubled at the depth of thirty-four feet below the surface of the water, and tripled at the depth of sixty-eight feet. This law was discovered by Dr. Hooke; he found, however, that when a very great pressure had been applied, so that the density became many times greater than in the natural state, the elasticity appeared to be somewhat less increased than the density.

Not only the common air of the atmosphere but also steams and vapors of all kinds, appear to be equally subject to this law: they must, however, be examined at temperatures sufficient to preserve them in a state of elasticity; for example, if we wished to determine the force of steam twice as dense as that which is usually produced, we should be obliged to employ a heat 30° or 40° above that of boiling water: we should then find that steam of such a density as to support, when confined in a dry vessel, the pressure of a column of thirty inches of mercury, would be reduced to half its bulk by the pressure of a column of sixty inches. But, if we increase the pressure much beyond this, the steam would be converted into water.

That the air of the atmosphere possesses weight, may be shown by weighing a vessel which has been exhausted by the air-pump, and weighing it a second time after allowing the air to enter. In this manner we also ascertain its specific gravity, even if the exhaustion is only partial, provided that we know the proportion of the air left in the vessel to that which it originally contained. The pressure derived from the weight of the air is also the cause of the ascent of hydrogen gas, or of any portion of air rarefied by heat; this effect is made conspicuous when either the hydrogen gas, or the heated air, is confined as in a balloon. The diminution of the apparent weight of a body, by means of the pressure of the surrounding air, is also shown by the destruction of the equilibrium between bodies of different densities, upon their removal into the vacuum of an air-pump.

This combination of weight and elasticity in the atmosphere, induces the supposition that its upper parts are much more rare than those which are near the earth, since the density is every where proportional to the whole of the superincumbent weight. The weight of a column of air one foot in height is $\frac{1}{28000}$th of the pressure; consequently that pressure is increased $\frac{1}{28000}$th by the addition of the weight of one foot, and the next foot will be denser in the same proportion, since the density is always proportionate to the pressure: the pressure thus increased will therefore still be equal to 28,000 times the weight of the next foot. The same reasoning may be continued without limit; and it may be shown, that while we suppose the height to vary by any uniform steps, as by distances of a foot or a mile, the pressures and densities will increase in continual proportion; thus, at the height of about 3000 fathoms, the density will be about half as great as at the earth's surface; at the height of 6000 one-fourth; at 9000 one-eighth as great. Hence it is inferred that the height in fathoms may be readily found from the logarithm of the number expressing the density of the air: for the logarithm of the number 2, multiplied by 10,000, is 3010, the logarithms of numbers always increasing

in continual proportion, when the numbers are taken larger and larger by equal steps. And thus we obtain an easy method of determining the heights of mountains: for if a bottle of air were closely stopped on the summit of a mountain, and, being brought in this state into the plain below, its mouth were inserted into a vessel of water or of mercury, a certain portion of the liquid would enter the bottle; this being weighed, if it were found to be one-half of the quantity that the whole bottle would contain, it might be concluded that the air on the mountain possessed only half of the natural density, or that its height was 3000 fathoms. Thus also it appears that the height of a column of equal density with any part of the atmosphere, equivalent to the pressure to which that part is subjected, is every where equal to about 28,000 feet. Various corrections, however, are necessary for ascertaining the heights of mountains with all the precision that the nature of this kind of measurement admits, involving a previous knowledge of the effects of heat, and of the nature of the ascent of vapors.

On the same principles we may ascertain the height to which a balloon will ascend, if we are acquainted with its bulk and weight: thus supposing its weight 500 lbs., and its bulk such as to enable it to raise 300 lbs. more, its specific gravity must be five-eighths as great as that of the air, and it will continue to rise until it reaches the height at which the air is of the same density: but the logarithm of eight-fifths multiplied by 10,000 is 2040; and this the number of fathoms contained in the height, which will, therefore, be a little more than two miles and a quarter. It may be found, by pursuing the calculation, that at the distance of the earth's semidiameter, or nearly 4000 miles above its surface, the air, if it exist, will become so rare, that a cubic inch would occupy a space equal to the sphere of Saturn's orbit: if, on the other hand, there were a mine forty-two miles deep, the air at the bottom would become as dense as quicksilver.

All bodies existing on or near the earth's surface, therefore, may be considered as subjected to the pressure of a column of air 28,000 feet high, supposing its density every where equal to that which it possesses at the earth's surface, and which is usually such, that 100 wine gallons weigh a pound avoirdupois, creating a pressure equal to that of thirty inches of mercury, or thirty-four feet of water, and which amounts to fourteen pounds and three quarters for each square inch. This pressure acts in all directions on every substance exposed to it: but, being counterbalanced by the natural elasticity of these substances, it produces in common no apparent effect. When, however, by any means the pressure of the air is removed from one side of a body, while it continues to act on the other, its operation becomes extremely evident. Thus, when two hollow hemispheres, in contact with each other, are exhausted of air, they are made to cohere with great force: Otto Guerike, of Magdeburg, constructed two such hemispheres, of sufficient magnitude to withstand the draught of the emperor's six coach horses, pulling with all their force to separate them. Hence they are sometimes called the Magdeburg hemispheres. By a similar pressure, a thin square bottle will, when it is sufficiently exhausted, be crushed, and a bladder may be torn with a loud noise: and the hand being placed on the mouth of a vessel connected with the air pump, it is fixed to it very forcibly, when the exhaustion is performed by the pressure of the air on the back of the hand; the fluids also, which circulate in the blood-vessels of the hand, are forced towards its lower surface, and the effect which is called suction is produced. On this principle cupping-glasses are made to act: partial exhaustion is procured by means of the flame of tow, which heats the air, expelling a great part of it; and the remainder, when it cools, becomes rarefied.

Galileo first explained the nature of suction from the effects of the pressure of the atmosphere; and Torricelli confirmed his doctrines by employing a column of mercury, of sufficient height to overcome the whole pressure of the atmosphere, and to produce a vacuum in the upper part of the tube containing it. In sucking up a fluid through a pipe, with the mouth or otherwise, the pressure of the air is but partially removed from the upper surface of the fluid, and it becomes capable of ascending to a height which is determined by the difference of the densities of the air within and without the cavity concerned; thus, an exhaustion of one-fourth of its air would enable us to raise water to the height of eight feet and a half, and mercury to seven inches and a half above the level of the reservoir from which it rises.

But when a tube of glass, about three feet long, closed at one end and open at the other, is filled with mercury, and them immersed in a basin of the same fluid, the pressure of the atmosphere is wholly removed from the upper surface of the mercury in the tube, while it continues to act on the mercury in the basin, and by its means on the lower surface of the column in the tube. If such a tube be placed under the receiver of an air-pump, the mercury will subside accordingly as the pressure of the atmosphere is diminished; and, if the exhaustion be rendered perfect, it will descend very nearly to the level of the open basin or reservoir. When the air is readmitted the mercury usually rises, on the level of the sea, to the height of about thirty inches; but, the air being lighter at some times than at others, varies between twenty-seven and thirty-one inches Such is the principle of the well-known instrument called the barometer. In order to observe the height of the mercury, with greater convenience and accuracy, the scale of this instrument has been amplified by various methods; by bending the upper part of the tube into an oblique position, as in the diagonal barometer; by making the lower part horizontal, and of much smaller diameter than the upper; or by making the tube straight, and narrow, and slightly conical; or by placing a float on the surface of the mercury in the reservoir, and causing an axis, which carries an index, to revolve by its motion. See our article Barometer. But a good simple barometer, about one-third of an inch in diameter, furnished with a vernier is perhaps full as accu-

rate as any of these more complicated instruments.

The method which is employed in determining the relation between the heights and densities of elastic fluids, may be extended to all bodies which are in any degree compressible, and of which the elasticity is subjected to laws similar to those which are discoverable in the air and other gases: it is even not improbable that these laws are generally applicable to all bodies, as far as their texture will allow them to submit to the operation of pressure. Water, for example, has been said by Canton to be compressible $\frac{1}{22000}$th of its bulk by a force equal to that of the pressure of the atmosphere; consequently this force may be represented by that of a column of water 750,000 feet in height; the density of the water at the bottom of a lake, or of the sea, will be increased by the pressure of the superincumbent fluid; and, supposing the law of compressure to resemble that of air, it may be inferred that, at the depth of 100 miles, its density would be doubled; and that at 200 it would be quadrupled. The same measures would also be applicable to the elasticity of mercury.

Sect. III.—The Temperature of the Atmosphere.

That the temperature of the air varies in different climates and seasons, as well as in the same place and in the same season, is sufficiently obvious. Nor can the cause of this perpetual variation be very simple: it cannot be the direct heat of the sun; for the rays of that luminary seem to produce no effect whatever upon air, though ever so much concentrated, although they warm the surface of the earth, which communicates its heat to the atmosphere: and hence it happens that the temperature of the air is highest in those places which are so situated as to be most warmed by the sun's rays, and that it varies in every region with the season of the year. Hence, too, the reason why it diminishes according to the height of the air above the earth. That portion of the earth, for instance, which lies at the equator, is exposed to the most perpendicular rays of the sun. Of course it is hottest, and the heat of the earth diminishes gradually from the equator to the poles. The temperature of the air must follow the same order. Yet, as in every place the temperature of the air is constantly varying with the season of the year, we cannot form any precise notion of the progression without taking the temperature in every degree of latitude for every day of the year, and forming for each a mean temperature for the whole year; which is done by adding together the whole observations, and dividing by their number. The quotient gives the mean temperature for the year. The diminution from the pole to the equator takes place in arithmetical progression: or, to speak more properly, the annual temperatures of all the latitudes are arithmetical means between the mean annual temperature of the equator and the pole. This was first discovered by Mr. Meyer; and by means of an equation which he founded on it, but rendered considerably plainer and simpler, Kirwan calculated the mean annual temperature of every degree of latitude between the equator and the pole. According to this calculation, that of the equator is 84°, and that of the pole 31°. To find the mean temperature, for every other latitude, we have only to find 88 arithmetical means between 84 and 31. In this manner Mr. Kirwan calculated the following table:—

Table of the Mean Annual Temperature of the Standard Situation in every Latitude.

Lat.	Temp.	Lat.	Temp.	Lat.	Temp.	Lat.	Temp.
90	31·	68	38·4	46	56·4	24	75·4
89	31·04	67	39·1	45	57·5	23	75·9
88	31·10	66	39·7	44	58·4	22	76·5
87	31·14	65	40·4	43	59·4	21	77·2
86	31·2	64	41·2	42	60·3	20	77·8
85	31·4	63	41·9	41	61·2	19	78·3
84	31·5	62	42·7	40	62·	18	78·9
83	31·7	61	43·5	39	63·	17	79·4
82	32·	60	44·3	38	63·9	16	79·9
81	32·2	59	45·09	37	64·8	15	80·4
80	32·6	58	45·8	36	65·7	14	80·8
79	32·9	57	46·7	35	66·6	13	81·3
78	33·2	56	47·5	34	67·4	12	81·7
77	33·7	55	48·4	33	68·3	11	82·
76	34·1	54	49·2	32	69·1	10	82·3
75	34·5	53	50·2	31	69·9	9	82·7
74	35·	52	51·1	30	70·7	8	82·9
73	35·5	51	52·4	29	71·5	7	83·2
72	36·	50	52·9	28	72·3	6	83·4
71	36·6	49	53·8	27	72·8	5	83·6
70	37·2	48	54·7	26	73·8	0	84·
69	37·8	47	55·6	25	74·5		

This table, however, only answers for the temperature of the atmosphere of the ocean. It was calculated for that part of the Atlantic Ocean which lies between 80° of N. and 45° of S. lat., and extends westward as far as the Gulf Stream, and to within a few leagues of the coast of America: and for all that part of the Pacific Ocean reaching from lat. 45° N. to lat. 40° S., from 20° to 275° of E. long. of London. This part of the ocean Mr. Kirwan calls the standard: the rest of the ocean is subject to anomalies which will be mentioned. Mr. Kirwan has also calculated the mean monthly temperature of the standard ocean. The principles on which he went were these:—The mean temperature of April seems to approach very nearly to the mean annual temperature; and, as far as heat depends on the action of the solar rays, the mean heat of every month is as the mean altitude of the sun, or rather as the sine of the sun's altitude. The mean heat of April, therefore, and the sine of the sun's altitude, being given, the mean heat of May is found in this manner: as the sine of the sun's mean altitude in April is to the mean heat of April, so is the sine of the sun's mean altitude in May to the mean heat of May. In the same manner the mean heats of June, July, and August, are found; but the rule would give the temperature of the succeeding months too low, because it does not take in the heat derived from the earth, which possesses a degree of heat nearly equal to the mean annual temperature. The

real temperature of these months therefore must be looked upon as an arithmetical mean between the astronomical and terrestrial heats.

But Mr. Kirwan, after going through a tedious calculation founded upon this principle, observed the results to agree so ill with experiment, that he drew up an extensive table of the monthly mean temperature of the standard from lat. 80° to lat. 10°, from which it appears that January is the coldest month in every latitude, and that July is the warmest month in all latitudes above 48°. In lower latitudes August is generally warmest. The difference between the hottest and coldest months increases in proportion to the distance from the equator. Every habitable latitude enjoys a mean heat of 60° for at least two months; this heat seems necessary for the production of corn. Within 10° of the poles the temperatures differ very little neither do they differ much within 10° of the equator; the temperatures of different years differ very little near the equator, but they differ more and more as the latitudes approach the poles.

2. That the temperature of the atmosphere gradually diminishes, according to its height above the level of the sea, is well known. Thus the late Dr. Hutton of Edinburgh found that a thermometer, kept on the top of Arthur's Seat, usually stood 3° lower than a thermometer kept at the bottom of it. Hence, then, a height of 800 feet occasioned 3° of diminution of temperature. On the summit of Pinchinca the thermometer stood at 30°, as observed by Bouguer, while at the level of the sea in the same latitude it stood at 84°. Here a height of 15,564 feet occasioned a diminution of temperature amounting to 54°. But, though there can be no doubt of the gradual diminution of temperature according to the height, it is by no means easy to determine the rate of diminution. Euler supposes it to be in a harmonic progression; but this opinion is contradicted by observations. Saussure supposes that in temperate climates the diminution of temperature amounts to 1° for every 287 feet of elevation. But Mr. Kirwan has shown that no such rule holds, and that the rate of diminution varies with the temperature at the surface of the earth. We are indebted to this philosopher for a very ingenious method of determining the rate of diminution in every particular case, supposing the temperature at the earth's surface known. See *Irish Trans.* viii. 356.

Since the temperature of the atmosphere is constantly diminishing as we ascend, it is obvious that at a certain height we arrive at the region of perpetual congelation. This region varies in height according to the latitude of the place; being highest at the equator, and descending gradually nearer the earth as we approach the poles. It varies also according to the season. M. Bouguer found the cold on the top of Pinchinca, one of the Andes, to extend from 7° to 9° below the freezing point every morning immediately before sun-rise. He concluded, therefore, that the mean height of the term of congelation (the place where it freezes during some part of the day all the year round) between the tropics was 15·577 feet above the level of the sea; but, in lat. 28°, he placed it in summer at the height of 13,440 feet. Now, if we take the difference between the temperature of the equator and the freezing point, it is evident that it will bear the same proportion to the term of congelation at the equator, that the difference between the mean temperature of any other degree of latitude and the freezing point bears to the term of congelation, in that latitude. Thus the mean heat of the equator being 84°, the difference between it and 32 is 52; the mean heat of latitude 28° is 72·3°, the difference between which and 32 is 40·3: Then 52 : 15577 :: 40·3 : 12072. In this manner Kirwan calculated the following Table:—

Lat.	Mean height of the Term of Congelation. *Feet.*	*Lat.*	Mean height of the Term of Congelation. *Feet.*
0°	15577	45°	7658
5	15457	50	6260
10	15067	55	4912
15	14498	60	3684
20	13719	65	2516
25	13030	70	1557
30	11592	75	748
35	10664	80	120
40	9016		

Beyond this height, which has been called the lower term of congelation, and which must vary with the season and other circumstances, Bouguer distinguished another, which he called the upper term of congelation; that is, the point above which no visible vapor ascends. Mr. Kirwan considers this line as much less liable to vary during the summer months than the lower term of congelation, and therefore has made choice of it to determine the rate of the diminution of heat, as we ascend in the atmosphere. Bouguer determined the height of this term in a single case and Kirwan has calculated the following table of its height for every degree of latitude in the northern hemisphere.

Table of the Height of the Upper Line of Congelation in the different Latitudes of the Northern Hemisphere.

N. Lat.	Feet.	N Lat.	Feet.	N. Lat.	Feet.	N. Lat.	Feet.
0°	28,000	26°	22,906	[illegible]	12,245	70°	4,413
5	27,784	27	22,389	[illegible]	11,750	[illegible]	4,354

[illegible]	23,633	[illegible]	13,235	68	4,548	90	3,432
25	23,423	47	12,740	69	4,480		

This method of estimating the diminution of temperature, has been found to agree remarkably well with observation; and hence it follows that the heat of the air at a distance from the earth would seem not to be owing to the ascent of hot strata of air from the surface of the earth, but to the conducting power of the air.

This rule, however, applies only to the temperature of the air during the summer months of the year. In winter the upper strata of the atmosphere are often warmer than the lower. Thus on the 31st of January, 1776, the thermometer on the summit of Arthur's Seat stood six degrees higher than a thermometer at Hawkhill, which is 684 feet lower.—Roy. Phil. Trans. 1777, p 777. Mr. Kirwan considers this superior heat, almost uniformly observed during winter, as owing to a current of warm air from the equator, which rolls towards the north pole during our winter.

Such, then, in general, is the method of finding the mean annual temperature all over the globe. There are, however, several exceptions to these general rules, which must here be mentioned.

That part of the Pacific Ocean which lies between N. lat. 52° and 66° is no broader at its northern extremity than forty-two miles, and at its southern extremity than 1300; it is reasonable to suppose, therefore, that its temperature will be influenced by the surrounding land, which consists of ranges of mountains, covered a great part of the year with snow; and there are besides a great many high, and consequently cold, islands scattered through it. For these reasons Mr. Kirwan concludes that its temperature is at least four or five degrees below the standard.

It is a well-known opinion that the southern hemisphere, beyond 40° of lat., is considerably colder than the corresponding parts of the northern hemisphere. Mr. Kirwan has shown that this holds with respect to the summer of the southern hemisphere, but that the winter in the same latitudes is milder than in the northern hemisphere.

Small seas surrounded with land, at least in temperate and cold climates, are generally warmer in summer and colder in winter than the standard ocean, because they are a good deal influenced by the temperature of the land. The Gulph of Bothnia, for instance, is for the most part frozen in winter; but in summer it is sometimes heated to 70°, a degree of heat never to be found in the opposite waters of the Atlantic. —Mem. Stock. 1776. The German Sea is above 3° colder in winter, and 5° warmer in summer than the Atlantic. The Mediterranean is, for the greater part of its extent, warmer both in summer and winter than the Atlantic. The Black Sea is colder than the Mediterranean.

The eastern parts of North America are much colder than the opposite coast of Europe, and fall short of the standard by about 10° or 12°. The causes of this remarkable difference are many. The highest part of North America lies between 40° and 50° of N. lat., and 100° and 110° of W. long. from London; for there the greatest rivers originate. The very height, therefore, makes this spot colder than it otherwise would be. It is covered with immense forests, and abounds with swamps and morasses, which render it incapable of receiving any great degree of heat; so that the rigor of winter is much less tempered by the heat of the earth than in the old continent. To the east lie a number of very large lakes; and, farther north, Hudson's Bay; about fifty miles on the south of which there is a range of mountains, which prevent its receiving any heat from that quarter. This bay is bounded on the east by the mountainous country of Labrador and by a number of islands. Hence the coldness of the north-west winds and the lowness of the temperature. But, as the cultivated parts of North America are now much warmer than formerly, there is reason to expect that the climate will become still milder when the country is better cleared of woods, though perhaps it will never equal the temperature of the old continent.

Islands are warmer than continents in the same latitude; and countries lying to the windward of extensive mountains or forests are warmer than those lying to the leeward. Stones or sand seem to have a less capacity for retaining heat than the other parts of the earth which are somewhat moist; they heat or cool, therefore, more rapidly, and to a greater degree. Hence the violent heat of Arabia and Africa, and the intense cold of Terra del Fuego. Living vegetables alter their temperature slowly, but their evaporation is great; and woody countries, as excluding the sun's rays from the earth, are much colder than those which are cultivated.

The atmosphere is affected by a general current from east to west, like that of the sea; and there is reason, from astronomical observations, to suppose that a similar circumstance happens in the atmosphere of Jupiter, on account of the actions of his satellites, which must be considerably more powerful than that of the moon.

The atmosphere is also liable to elevations and depressions analogous to those of the sea, and perhaps these changes may have some little effect on the winds and on the weather. 'The height of an aerial tide must,' says Dr. Young, 'be nearly the same with the observed height of the principal tides of the sea; and the variation of atmospherical pressure, which is measured between the difference of the actual form and the spheroid of equilibrium, must be equivalent to the weight of a column of about ten feet of air, or only $\frac{1}{100}$ of an inch of mercury. A periodical variation five times as great as this has, indeed, been observed near the equator, where the state of the atmosphere is the least liable to accidental disturbances; but this change cannot in any degree be referred to the effect of the moon's action, since it happens always about the same hour of the day or night.'

'The exact specific gravity of atmospherical air,' says Dr. Ure, 'compared to that of water, is a very nice and important problem. By reducing to 60° Fahr., and to thirty inches of the barometer, the results obtained with great care by MM. Biot and Arago, the specific gravity of atmospherical air appears to be 0·001220, water being represented by 1·000000. This relation expressed fractionally is $\frac{1}{820}$, or water is 820 times

denser than atmospherical air.' Mr. Rice, in the seventy-seventh and seventy-eighth numbers of the Annals of Philosophy, deduces from Sir George Shuckburgh's experiments 0·00120855 for the specific water of air. This number gives gravity to air as 827·437 to 1. If, with Mr. Rice, we take the cubic inch of water = 252·525 grs., then 100 cubic inches of air, by Biot's experiments, will weigh 30·808 grains, and by Mr. Rice's estimate 30·519. He considers with Dr. Prout the atmosphere to be a compound of four volumes of nitrogen, and one of oxygen; the specific gravity of the first being to that of the second as 1·1111 to 0·9722.

Hence

0·8 vol. nitr. sp. gr. .	0·001166	= 0·000933
0·2 oxy. . .	0·001340	= 0·000268
		0·001201

The numbers are transposed in the Annals of Philosophy by some mistake.

MM. Biot and Arago found the specific gravity of oxygen to be . . 1·10359
and that of nitrogen . . . 0,96913
air being reckoned . . . 1·00000

Or compared to water as unity—

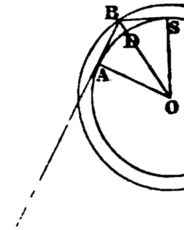
Nitrogen is .	0·001182338	
Oxygen . .	0·001346379	
And 0·8 nitrogen		= 0·00094587
0·2 oxygen		= 0·00026927
		0·00121514
And 0·79 nitrogen		= 0·000934
0·21 oxygen		= 0·000283
		0·001217

A number which approaches very nearly to the result of experiment. Many analogies, it must be confessed, favor Dr. Prout's proportions; but the greater number of experiments on the composition and density of the atmosphere agree with Biot's results. Nothing can decide these fundamental chemical proportions except a new, elaborate, and most minutely accurate series of experiments. We shall then know whether the atmosphere contains in volume 20 or 21 per cent. of oxygen.

On the subject of the *height of the atmosphere*, see the article Atmosphere. In addition to what is there stated, the famous problem of Kepler, as to its extent, should perhaps be noticed. He contended that the depression of the sun below the horizon, when twilight appears, will furnish data for ascertaining the altitude of the atmosphere, or at least of that portion of it which reflects the sun's parting rays.

Let S of the diagram, fig. 1, be the situation of a spectator on the surface of the earth, and A the point where the sun sets. The tangent, A B, will now mark the path of the lowest solar ray, which illuminates the highest part of the atmosphere at B, whence the emission of a secondary ray, B S, will barely reach the ground at A. But assuming the ordinary estimate, that twilight expires when the solar depression or the arc S A amounts to 18°, in the right-angled triangle S O B, the base O S, or the radius of the globe being 3956, and the acute angle S O B 9°, or the half of A O S, the hypothenuse O B is easily found,

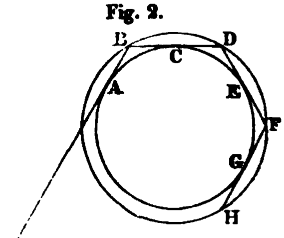
Fig. 1.



and hence about forty-nine miles is the excess B D of S B above S D, or the elevation of the limit of the atmosphere, enlightened by the sun's last rays. Some correction may be required for the deviation of rays from the rectilineal path, in consequence of the unequal refraction of them in different atmospheric strata; but this calculation is sufficiently near, and the suggestion was most ingenious.

M. Lambert, however, pushes this problem yet further. He observes (fig. 2) that we may

Fig. 2.



easily conceive that the rays S B, after impinging on the earth's surface at A, will illuminate the atmosphere to B, from which light will be darted in the direction of B C D, to tinge another elevated portion of the atmosphere at D, which will again cast rays on the spectator at E, or shoot onwards to the opposite sky at F, and thence reach, almost in a state of extinction, the ground at G. While, therefore, the first crepusculum would set in the west, the second would travel like a bow over the heavens, followed at a regular distance by the dusky veil of the third and fourth.

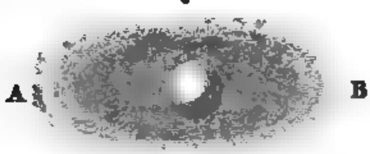
'But it may be computed,' observes Mr. Leslie, 'from the vast length of the tracts which the light would have to traverse, that those shades would in succession be 10,000 times darker.' The clearest sky, however, on the close of evening, never appears marked by such contrasts. 'It is most probable, therefore, that the diminution of light, after the close of evening, is owing to the prodigious rarefaction of much higher portions of the atmosphere, which still catch some faint rays of the sun, without being able, from excessive attenuation, to reflect them efficiently to the earth. But since, unless the sky be overcast, there is total darkness in no climate, even at midnight; we may, therefore, infer that the body of air extends to such an altitude as to receive the most dilute glimmer, after the

sun has attained its utmost obliquity, and sunk 90° below the horizon. It would thence follow that the elevation of the atmosphere must be equal at least to 1638 miles, or the excess of the hypothenuse of an isosceles right-angled triangle having 3956 miles, or the radius of the earth, for its base

'This very great extension of a rare expansive atmosphere appears conformable to the general phenomena. But the thin investiture of our globe, at least near the equator, may stretch out much farther; and yet its elevation can never exceed a certain absolute limit. The highest portions of the atmosphere, which is carried round in twenty-three hours and fifty-six minutes by the rotation of the earth about its axis, would be projected into space, if their centrifugal force at that distance were not less than their gravitation towards the centre. But the centrifugal force is directly as the distance, while the power of gravity is as its square. Consequently, when the centrifugal force at the distance of 6·6 radii of the earth is augmented as many times, the corresponding gravitation is diminished by its square or 43·7 times, their relative proportion being thus changed to 289. Now, the centrifugal force being only the 289th part of gravity at the surface of the equator, it will therefore just balance this power at the distance of 6·6 radii from the centre, or at the elevation of 22,200 miles.' Art. METEOROLOGY. *Supplement to the Encyclopædia Britannica.*

This writer observes, in defence of his hypothesis, that such an extent of atmosphere will occupy scarcely a twentieth part of the distance between the earth and the moon, which the ancients held to communicate with the atmosphere. He thus exhibits what he conceives the true figure of the earth and atmosphere. A B fig. 3 is the equatorial diameter.

Fig. 3.

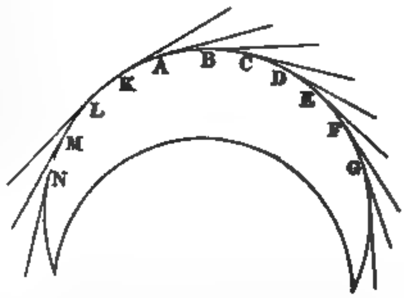


SECT. IV.—HYPOTHESIS RESPECTING THE VARIATIONS OF THE BAROMETER.

In our article BAROMETER we have noticed the early conjectures respecting the causes of the irregularities of that important instrument, and the valuable remarks of Deluc, Laplace, &c., on this subject. Mr. Leslie is, however, dissatisfied with every former theory on this point. 'The transition of the air from a state of dryness to humidity, seemed,' he says, 'to furnish the most plausible explication of the changes of the mercurial column. But the indication of the barometer was, in this case, distinctly at variance with the ordinary feelings of men. Those who suffer under a delicate or enfeebled constitution are accustomed in damp weather to complain of the air as heavier and less elastic. This language is, no doubt, metaphorical only, and descriptive of the disordered state of the nervous system; but it shows the utter fallacy of trusting in philosophical matters to the loose results of vulgar observation and experience. Moisture, so far from loading the air by its weight, communicates, like heat, increased expansion and elasticity. But, even supposing a column of air to become charged with humidity, before its subsequent dilatation had, by diffusing it, produced an equilibrium, still the additional pressure would have been extremely small, not exceeding, at a moderate computation, the fifteenth part of a mercurial inch. Any transition of that medium, from dryness to humidity, would be quite inadequate, therefore, to the production of the effects actually observed.'

He afterwards suggests the deflected course of a *horizontal current of air* as the most probable cause of these phenomena. 'Suppose,' he says, 'a current to begin to flow from A (fig. 4) in

Fig. 4.



the direction of a tangent, it will successively bend from a rectilineal track at the points B, C, D, E, F, G, &c., on the surface of the earth. The particles of the fluid are, therefore, drawn incessantly from their course by the action of gravity. Their vertical pressure is consequently diminished by the force spent in producing this deflection. During the prevalence of the wind the atmospheric column will press with inferior weight at B than at A, at C than at B, at D than at C; thus gradually decreasing through the whole chain. Suppose the intervals A B, B C, C D, D E, &c., to be each of them a mile, and that the current reaches the points B, C, D, E, &c., in successive minutes, a celerity which frequently happens; the deflection at B, owing to the curvature of the earth, would be eight inches, or two-thirds of a foot; but the space through which a body would descend in a minute, by the action of gravity, is $60 \times 60 \times 16 = 57600$ feet, or 86400 times greater than the deviation from the tangent. Wherefore the atmospheric pressure would, on that hypothesis, be diminished by the $\frac{1}{86400}$th part for each interval of a mile, from A to G. In the space of 288 miles this diminution would consequently be the $\frac{1}{300}$th part of the incumbent weight; and over an extent of 2880 miles it would amount to the thirtieth part. If we assume the very probable estimate, that storms involve the whole region of the clouds, or attain an elevation of nearly three miles, the diminution of pressure, occasioned by a long series of deflections in the stream, would affect one-half

of the atmosphere. Wherefore, a wind which has blown over a track of 2880 miles, at the rate of sixty miles an hour, might cause the mercurial column to subside half an inch. If the velocity of the wind were doubled, which is probably the limit of the most tremendous hurricane, the fall of the barometer would be four times greater, and amount to two inches. That the same powerful wind can sweep over an immense track of surface is well ascertained. The effects of a hurricane originating in the West Indies, at the distance of 5000 miles, have often been felt on our shores. But a wind arising at A must evidently be followed, at succeeding intervals, by a current from K, L, M, &c., the range of influence being thus extended over a larger track. During the flow of the air the depression of the barometer at G will be maintained, or rather augmented.'

He afterwards suggests that the winds, though thus regarded as describing only great circles about the earth, may be constrained to bend into smaller ones; and thus exert even a greater influence over the barometer. Thus also he would explain the phenomena of eddies, whirlwinds, and tornadoes. See Winds.

Sect. V.—Theory of Mists, Dews, and Rain.

Sir Humphry Davy in a paper inserted in the Philosophical Transactions 1819, part I., suggests that land and water cool after sunset in a very different manner. The impression of cooling on the land is limited to the surface, and is very slowly transmitted into the interior; whereas in water the upper stratum, when cooled, descends, and has its place supplied by warmer water from below. The surface of the water will therefore, in calm and clear weather, and in temperatures above 45° Fahrenheit, be warmer than that of the contiguous land; and consequently the air above the land will be cooler than that above the water. When the cold air, therefore, from the land mixes with that above the water, both of them containing their due proportion of aqueous vapor, a mist or fog must be the result.

It is necessary, therefore, for the formation of mists, that the temperature of the water should be greater than that of the air: for the deposition of dew (according to Dr. Wells, see our article Dew), requires that the heat of the body on which it is deposited should be less than that of the atmosphere.

There are three principal conditions to be considered, when the formation of dew is taken in conjunction with that of mist, according to an able paper of Mr. Harvey's of Plymouth, in the Edinburgh Philosophical Journal.

In the first place the temperature of the water, and the law according to which it cools; secondly, the temperature of the land, and the law by which it radiates its heat to the sky; and, thirdly, the quantity of vapor contained in the air. The varied character of these conditions must necessarily impart a corresponding diversity to the results. The same circumstances of temperature which in one case would produce a copious deposition of dew, and a mist of considerable density, in another case would produce only a moderate formation of each; and, even if we suppose the quantity of atmospheric moisture to remain constant, alterations of temperature will occasion innumerable varieties of both.

'When the atmosphere is completely saturated with vapor, the greatest quantity of dew will be deposited, when the land, by a free radiation to a pure and tranquil sky, has its temperature diminished by the greatest possible quantity below that of the air reposing on its surface; and a mist of the greatest degree of density will be formed, when the temperature of the adjacent water is above that of its superincumbent air, also by the greatest possible quantity. The temperatures of the two masses of air, although unequal, may therefore be regarded as occupying a kind of middle state between the extremes here alluded to. In all cases the density of a mist will be jointly proportional to the difference of temperature between the sea and land, and the quantity of vapor held in solution by the atmosphere at the time of its formation.

'To show, however, the quantities of moisture that will be precipitated in the form of mist, fog, or rain, from the mingling together of equal masses of perfectly saturated air, of different degrees of temperature, the following examples are given; from which it will be perceived that the moisture deposited increases with the difference of temperature of the volumes of air. The temperatures are those of the centesimal scale; and the grains of vapor are what a metrical cube of air contains at the respective temperatures, when in a state of saturation, according to the experiments of professor Leslie.

Temperatures.	Grains of vapor dissolved in a metrical cube of Air, at the respective Temperatures.	Means of the preceding.	Grains of Vapor dissolved in a metrical cube of Air, at the means of the respective Temperatures.	Grains of Vapor deposited in the form of Mist, Fog, or Rain.
4° 6	120·3 132·0	126·1	126·0	0·1
4 8	120·3 144·7	132·5	132·0	0·5
4 10	120·3 158·7	139·5	138·2	1·3
4 12	120·3 174·1	147·2	144·7	2·5
4 14	120·3 191·0	155·6	151·6	4·0
4 16	120·3 209·5	164·9	158·7	6·2
4 18	120·3 229·7	175·0	166·2	8·8
4 20	120·3 252·0	186·1	174·1	12·0

It appears from this table that, when the difference between the temperatures of the two metrical cubes of air amount to two centesimal degrees, the quantity of vapor deposited by a

metrical cube of the mixed air amounts only to one-tenth of a grain, whereas the union of similar volumes at the temperatures of 4° and 20°, occasions a precipitation of twelve grains. The greater the difference, therefore, between the temperatures of the equal masses of air, the greater will be the density of the mist formed by their union. It does not follow, however, that nature, in the infinite diversity of her operations, is confined, as in the particular case here considered, to the mingling together of equal volumes of perfectly saturated air, or of air containing a less proportion of moisture. Two or more parts of one particular temperature, and with any assignable degree of moisture, may be blended with other proportions of air, of a different temperature, and having other relations of moisture; and from such will arise mists of every variety of density.

Circumstances may be favorable, according to this writer, to the deposition of dew on the borders of rivers, without contributing to the formation of mists. The atmosphere contains, at all times, some moisture; and, therefore, when the relations of the temperature of the air and land are suitable, and a clear and tranquil sky prevails, a deposition of dew of some degree or other will take place. But, although the relations of temperature between the land and water may be favorable to the formation of mist, it by no means follows that the union of volumes of air, of unequal temperatures, will produce a visible condensation. In some examples which I have witnessed, says Mr. Harvey, the extreme tenuity of the mist has indicated, that the circumstances of temperature and vapor were such as just to admit of its formation.

'The deposition of dew,' he concludes, 'must always precede the formation of mists. This will appear evident, when we consider the principles to which each owes its origin. Suppose at some moment an equality of temperature to take place between the water, the land, and the volumes of air reposing over each. In consequence of the unequal cooling powers of the land and water, the former will first have its temperature reduced below that of the air: and although by this diminution the equality of temperature between the two volumes of air will be destroyed, and a condition created favorable to the formation of mist; still, as the cooling of the first volume and the mingling of the two are not contemporaneous acts, dew will be the first deposited. In proportion, however, as the land radiates freely, with the same rapidity must the temperature of the superincumbent air be diminished, and the equilibrium between it and the atmosphere hovering over the water be disturbed. The rapid formation of dew is therefore accompanied by circumstances favorable to the quick formation of mist; and it hence becomes probable, that, under such conditions, mist will be formed at an earlier period of the night, than when the land radiates less copiously, and dew is deposited in less abundance.

'If, in consequence of the interposition of a canopy of clouds, the cooling of the land and water should be checked, and an equality of temperature be restored between the two masses of air, and the bodies on which they respectively repose, the deposition of dew will be suspended, and likewise all tendency to the farther formation of mist. The entire dissipation of the latter may likewise result from the change. Or if we suppose a temporary interposition of clouds, and conceive the land to radiate its heat only at intervals, corresponding changes of temperature will immediately follow; an increase of heat taking place when the sky is obscured, and a diminution when its clearness is restored. Dr. Wells has furnished a case wherein the temperature of grass increased 15° in the short space of forty-five minutes, and which was at the same time accompanied by an elevation in the temperature of the air of 3½°. Nor is it improbable but that examples sometimes occur, of dew and mist being deposited in the former part of the night, and both disappearing before the morning; or, as it may sometimes happen, the former be preserved, and the latter dissipated. The first of these phenomena may take place, when a portion of the night, favorable to the formation both of mist and dew, is succeeded by a brisk wind; and the second, when, by the interposition of dense clouds, the temperature of the land is raised, which, by imparting its influence to its superincumbent air, restores it to a temperature equal to, or even greater than, that of the atmosphere reposing on the water, ultimately causing the mist to disappear, from the increased capacity of the air for vapor. This latter circumstance will also account for the dispersion of mists in the morning, before the disappearance of dew. The gentle motion that must also take place, from the mingling of the cold air from the land with the warmer air above the water, will have a tendency to increase the deposition of dew, since new volumes of air will be successively brought into contact with the cold surface of the earth, and by depositing their moisture, will augment the quantity of dew beyond what would otherwise have been formed, had the atmosphere remained perfectly calm. Dr. Wells found that a slight agitation of the air was always accompanied with an increase of dew. The general tenor of these observations is confirmed by a remark of the same indefatigable observer, that 'dew is always very copious on those clear and calm nights which are followed by misty or foggy mornings.''

Dr. Hutton's theory of rain we have already noticed in the article Clouds. Mr. Leslie, who fully espouses this theory, says, 'The profuse precipitation of humidity is caused by a rapid commixture of opposite strata. The action of swift contending currents in the atmosphere brings quickly into mutual contact vast fields of air over a given spot. The separation of moisture is hence proportionally copious. In temperate weather this deposition forms rain; but, in the cold season, the aqueous globules, freezing in the mid-air into icy spiculæ, which collect in their slow descent, become converted into flakes of snow. Hail is formed under different circumstances, and generally in sudden alternations of the fine season, the drops of rain being congealed during their fall, by passing through a lower stratum of dry and cold air.

'The drops of rain vary in their size perhaps from the twenty-fifth to a quarter of an inch in diameter. In parting from the clouds, they precipitate their descent till the increasing resistance opposed by the air becomes equal to their weight, when they continue to fall with a uniform velocity. This acquired or terminal velocity is therefore in the subduplicate ratio of the diameters of the aqueous globules. A thunder shower hence pours down much faster than a drizzling rain. In general, if d express the diameter of a drop in parts of an inch, the terminal velocity, according to theory, will be denoted by $78\sqrt{d}$, or, if the usual correction be made for the discrepancy in fluids, it will be $67\sqrt{d}$. Thus a drop of the twenty-fifth part of an inch, in falling through the air, would only gain a celerity of eleven feet and a half, while one of a quarter of an inch would acquire a celerity of thirty-three feet and a half. A flake of snow, being perhaps nine times more expanded than water, would descend thrice as slow. But hail-stones are often of considerable dimensions, exceeding sometimes the length of an inch. They may hence fall with a velocity of seventy feet each second, or at the rate of about fifty miles in the hour. Striking the ground with such impetuous force, it is easy to conceive the extensive injury which a hail shower may occasion in the hotter climates. The destructive power of those missiles, in stripping and tearing the fruits and foliage, increases besides in a faster ratio than the momentum, and may be estimated by the square of their velocity multiplied into mass. This fatal energy is hence as the fourth power of the diameter of the hail-stone.'

Mr. Luke Howard of London, one of our ablest writers on the subject of clouds, is inclined to attribute rain, with abbé Nollet and Beccaria, to the electrical action of the clouds upon each other.

In the formation of the rain-cloud (nimbus), two circumstances, he thinks, claim particular attention; the spreading of the superior masses of cloud, in all directions, until they become like the stratus one uniform sheet; and the rapid motion, and visible decrease, of the cumulus when brought under the latter. The cirri also, which so frequently stretch from the superior sheet upwards, and resemble erected hairs, carry much the appearance of temporary conductors for the electricity, extricated by the sudden union of minute particles of vapor, into the vastly larger ones that form the rain. By one experiment of Cavallo's, with a kite carrying 360 feet of conducting string, in an interval between two showers, and kept up during rain, it seems that the superior clouds possessed a positive electricity before the rain, which, on the arrival of a large cumulus, gave place to a very strong negative, continuing as long as it was over the kite. We are not, however, warranted from this to conclude the cumulus which brings on rain always negative, as the same effect might ensue from a positive cumulus uniting with a negative stratus. Yet the general negative state of the lower atmosphere during rain, and the positive indications commonly given by the true stratus, render this the more probable opinion. It is not, however, absolutely necessary to determine the several states of the clouds which appear during rain, since there is sufficient evidence in favor of the conclusion, that clouds formed in different parts of the atmosphere operate on each other, when brought near enough, so as to occasion their partial or entire destruction; an effect which can be attributed only to their possessing beforehand, or acquiring at the moment, the opposite electricities.

'It may be objected,' says Mr. Howard, 'that this explanation is better suited to the case of a shower than to that of continued rain, for which it does not seem sufficient. If it should appear, nevertheless, that the supply of each kind of cloud is by any means kept up in proportion to the consumption, the objection will be answered. Now, it is a well known fact, that evaporation from the surface of the earth and waters, often returns and continues during rain, and consequently furnishes the lower clouds, while the upper are recruited from the quantity of vapor brought by the superior current, and continually subsiding in the form of dew, as is evident both from the turbidness of the atmosphere in rainy seasons, and the plentiful deposition of dew in the nocturnal intervals of rain. Neither is it pretended that electricity is any farther concerned in the production of rain, than as a secondary agent, which modifies the effect of the two grand predisposing causes,—a falling temperature, and the influx of vapor.'

Mr. Dalton, who has also paid much attention to this subject, read before the Manchester Society an elaborate and interesting memoir on rain, from which we extract the following table and observations.

Mean Monthly and Annual Quantities of Rain at Various Places, being the averages for many years, by Mr. Dalton.

Observations on the theory of rain.—'Every one must have noticed an obvious connexion between heat and the vapor in the atmosphere. Heat promotes evaporation, and contributes to retain the vapor when in the atmosphere, and cold precipitates or condenses the vapor. But these facts do not explain the phenomenon of rain, which is as frequently attended with an increase as with a diminution of the temperature of the atmosphere.

'The late Dr. Hutton of Edinburgh was, I conceive, the first person who published a correct notion of the cause of rain. See Edinburgh Transactions vol. i. and ii. and Hutton's Dissertations, &c. Without deciding whether vapor be simply expanded by heat, and diffused through the atmosphere, or chemically combined with it, he maintained from the phenomena that the quantity of vapor capable of entering into the air increases in a greater ratio than the temperature; and hence he fairly infers that, whenever two volumes of air of different temperatures are mixed together, each being previously saturated with vapor, a precipitation of a portion of vapor must ensue, in consequence of the mean temperature not being able to support the mean quantity of vapor. The cause of rain, therefore, is now, I consider, no longer an object of doubt. If two masses of air, of unequal temperatures, by the ordinary currents of the winds are intermixed, when saturated with vapor, a precipitation ensues. If the masses are under saturation, then less precipitation takes place, or none at all, according to the degree. Also the warmer the air, the greater is the quantity of vapor precipitated in like circumstances. Hence the reason why rains are heavier in summer than winter, and in warm countries than in cold.

'We now enquire into the cause why less rain falls in the first six months of the year than in the last six months. The whole quantity of water in the atmosphere in January is usually about three inches, as appears from the dew point, which is then about 32°. Now the force of vapor at that temperature is 0·2 of an inch of mercury, which is equal to 2·8 or three inches of water. The dew point in July is usually about 58° or 59°, corresponding to 0·5 of an inch of mercury, which is equal to seven inches of water; the difference is four inches of water, which the atmosphere then contains more than in the former month. Hence, supposing the usual intermixture of currents of air in both the intervening periods to be the same, the rain ought to be four inches less in the former period of the year than the average, and four inches more in the latter period, making a difference of eight inches between the two periods, which nearly accords with the preceding observations.'

On the subject of the electricity of the atmosphere, see Electricity.

For the current of the atmosphere and the origin of winds, see Winds.

Sect. VI.—Of the Modern Meteorological Instruments.

Modern times, and the researches of the many eminent experimenters in this science, have given birth to a variety of excellent meteorological instruments which will generally be found described in their alphabetical place. See Barometer, Hygrometer, Thermometer, Wind Gauge, &c. Under the article Thermometer will be found the photometer and æthrioscope, both species of the differential thermometer; the atmometer, cyanometer, drosometer, and embrometer or rain-guage we shall here describe.

The *atmometer*, or evaporometer, is designed to measure the quantity of water evaporated in any given time. A circular basin, of uniform width from top to bottom, is the simplest form of the instrument: it is filled with water and the quantity evaporated may be ascertained by means of a graduated glass tube, similar to that employed

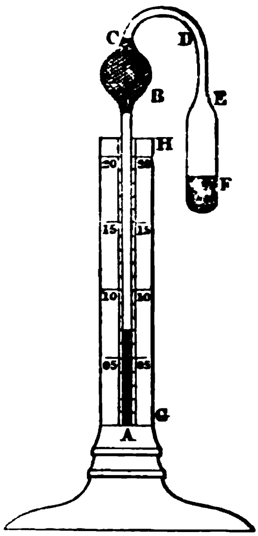
for measuring the depth of rain. There are difficulties, however, attending the use of the instrument, which often render it an uncertain indication of the absolute quantity evaporated. If it be fully exposed to the sun and wind, the heat acquired by the vessel will rapidly promote evaporation; and if the basin be kept nearly full, as it ought to be, the water will be agitated and thrown about by the wind.

A few years ago Mr. Leslie constructed an instrument of this kind on a very simple principle. It consisted of a ball of porous earthenware, two or three inches in diameter, into which was inserted a glass tube, so graduated that the quantity of water contained between two divisions of it would cover the outer surface of the ball to the depth of the $\frac{1}{1000}$th part of an inch. The ball and tube being filled with water, the top of the latter was covered with a brass cap, which, by means of a leather collar and screw, was made air-tight, and the instrument, being suspended out of doors, was freely exposed to the wind. In this state the humidity exuded through the surface of the ball as fast as it evaporated, and the descent of the column in the tube indicated the quantity evaporated. The pressure of the atmosphere being in a great measure removed, by the tightness of the collar, the water is prevented from passing through the ball of this instrument so quickly as to drop, while the space which it leaves empty at the top is occupied by the very minute stream of air which is imbibed by the moisture on the outside, and may be seen rising through the water in the tube.

'Of this instrument,' Mr. Leslie says, 'if the atmometer had its ball perfectly screened from the agitation of wind, its indications would be proportional to the dryness of the air at the lowered temperature of the humid surface; and the quantity of evaporation every hour, as expressed in the $\frac{1}{1000}$th part of an inch, would, when multiplied by twenty give the hygrometric measure. For example, in this climate, the mean dryness in winter being reckoned 15°, and in summer 40°, the daily exhalation from a sheltered spot must in winter form a thickness of ·018, and amount in summer to ·048 decimal parts of an inch. Suppose a pool for the supply of a navigable canal exposed a surface equal to ten English acres, and that the atmometer sank eighty parts during the lapse of twenty-four hours; the quantity of water exhaled in that time would be $\frac{80}{12000} \times 660 \times 66 \times {\cdot}10$, or 2904 cubic feet, which corresponds to the weight of eighty-one tons.

But the atmometer since invented by Mr. Anderson seems the best instrument of the kind hitherto proposed: it is thus described in the Edinburgh Philosophical Journal:—

Let A B C D E F represent a bent glass tube of sufficient width to admit of a liquid moving easily from one part to another, and swelling out into the bulbs B C and E F. Into this tube at A is introduced a quantity of alcohol, which, after being conveyed into the bulb or wider tube E F, is thrown into a state of ebullition; and, while the steam is issuing from A, the tube is there hermetically sealed, so that the air is completely expelled from the space A B C D E. The bulb B C is then covered with moistened silk or paper, and the instrument freely exposed. In consequence of the pressure of the air being removed from the surface of the alcohol, in the bulb E F, a portion of that liquid passes into vapor, and occupies the empty part of the tube. Were the whole of the instrument at the same temperature, this process would in deed quickly be stopped by the pressure of the vapor itself on the surface of the alcohol; but, as the bulb B C has its temperature reduced by the external evaporation from the moistened silk or paper, the vapor which rises from E F is there condensed, and runs down in a liquid state into the tube A B. This distillation goes on more or less rapidly, according to the degree of cold induced upon the bulb B C, that is, in proportion to the external evaporation; and, consequently, the quantity of liquid collected in the tube A B is a measure of that evaporation. When the atmosphere is completely saturated with moisture, or when the evaporation ceases, the temperature of A B will be the same as that of any other part of the tube; and the distillation, therefore, for the reason already stated, will also cease.



'The measure of evaporation thus found is expressed in inches and decimals of an inch, by means of an attached scale G H, the divisions of which are determined by experiment. Suppose, for example, that the instrument is exposed to similar circumstances with an evaporating basin, and that the quantity evaporated from the latter in a given time, as determined either by weight or measurement, is found to be one-tenth of an inch, while the alcohol distilled by the former in the same time fills the tube A B to the depth of one inch; then the scale, being divided into inches and tenths, will indicate tenths and hundredths of an inch of evaporation. By increasing the proportion between the diameters of E F and A B, the quantity of evaporation may be measured to any degree of minuteness required. In using the instrument, the tube E F is to be sheltered from rain by enclosing it in a case or cover, to prevent its temperature being reduced below that of the atmosphere by subsequent evaporation; and the bulb B C is to be kept constantly moist by means of a small cup containing water attached to the tube immediately below it, the silk or paper being in contact with the water, or from an adjoining vessel, as in the case of the hygrometer. The instrument is placed in a vertical position, and is prepared for a new observation by inverting it, so that the distilled alcohol

may be conveyed back to the tube E F. It is to be hoped that this beautiful and ingenious contrivance will soon meet with that reception among meteorologists to which its merits so well entitle it. This atmometer has already been constructed, and is found to possess the utmost delicacy. It is probable that it may in time supersede the use even of the hygrometer.'

The *cyanometer* (κυανος, cœrulean or sky-blue, and μετρον, a measure), is an invention of M. de Saussure to measure the intensity of the blue color of the atmosphere. It consists of a circular band of paper, divided into fifty-three parts, each of which was painted with a different shade of blue; beginning with the deepest mixed with black, to the lightest mixed with white. He found that the color of the sky always corresponded with the deepest shade of blue the higher the observer is placed above the surface. The color becomes always lighter in proportion to the vapors mixed with the air. From morning till noon, the color of the vertical sky darkened, but became lighter again as the evening advanced; and this transition was wider and more rapid in great elevations. On the Col du Geant the tint of the horizontal air at sunrise was five, it deepened to eleven and a half at noon, but again relapsed to five towards night. On the 15th of July, which was a very clear day, the atmosphere at the horizon had the eleventh shade; at the altitude of 10° the twentieth; at that of 20° the thirty-first; at that of 30° the thirty-fourth; at that of 40° the thirty-seventh; and thence with any sensible variation to the zenith. Humboldt found, in his voyage from Corunna to Cumana, the tints of the sky to vary by the cyanometer, from thirteen to twenty-four, and again to sixteen, while the color of the ocean fluctuated between thirty-four and forty-four.

Some writers have considered these experiments to prove that the color of the atmosphere is wholly owing to its vapors; and that, at a certain height, the blue will disappear altogether, and the sky appear black; that is to say, will reflect no light at all. Mr. Leslie on the other hand (and we confess his reasoning appears to us correct) considers air like water, to be by its constitution a colored fluid. The former, he says, is naturally blue, as the latter is green; but these colors acquire intensity only from the *depth* of the transparent mass. A small body of limpid water has the appearance of crystal, but, in proportion as it accumulates, it assumes all the successive shades till it rivals the tints of the emerald and the beryl. This gradation is distinctly seen in the profound lakes of Switzerland, whose lustre is never stained by any vegetable infusion. The same series of colors emerges, on receding from our shores and approaching the vast abyss of the Atlantic Ocean. At first the water on the shelving banks is merely translucid; at the depth of ten fathoms it appears greenish, and the tint, by degrees, becomes more intense till it passes into a full green, at the depth of fifty fathoms; but, beyond soundings, it darkens almost into azure. In like manner the blue shade of the air becomes more intense in proportion to the length of the tract of light. This we perceive in viewing distant objects, whose colors are always tinted by the deepening hues of the interjacent range of atmosphere. The remotest hills seem lost in a cœrulean vesture. The mixture of aqueous vapors only diffuses a mist, which tarnishes rather than dilutes the fine blue.'

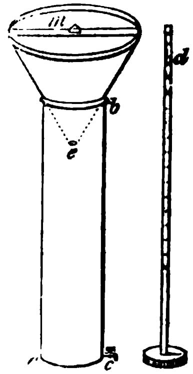
The *drosometer*, or dew-balance, is an instrument proposed by M. Weidlen of Germany, so far back as 1727, to measure, or rather weigh, the quantity of dew that falls on the surface of a body exposed to the night air. It consists of a bent balance, marked in grains which show the preponderance which a piece of glass of certain dimensions, laid horizontally in one of the scales, acquires, from the settling of the globules of moisture upon it. The main objection to this instrument, as to several others of a meteorological kind, is, that it requires to be protected from the wind, which cannot be accomplished without also screening it from a large portion of the dew that falls. The steel beam, too, soon loses its polish, and thus becomes unfit for accurate observation.

A more convenient drosometer is proposed by Mr. Leslie on the principle of the ombrometer, or rain-gauge. 'Suppose a glass funnel, of about three inches diameter, whose interior surface is very smooth and slopes towards the centre, at an angle of fifteen or twenty degrees, to be joined hermetically to a long tube, sealed at the lower end, and having an equable bore not exceeding a quarter of an inch, with an attached scale divided into portions, corresponding to the $\frac{1}{1000}$th parts of an inch, on the external aperture. The only difficulty is to make the dew which gathers during the night to run down the sides of the funnel into the tube. To facilitate this descent, a coat of deliquated salt of tartar may be spread with a hair pencil over the shallow surface, and renewed as often as occasion requires. The dew, instead of settling in minute detached globules, would then be attracted by the alkaline lye, which thus becoming dilute would gradually flow into the narrow cavity of the tube. It would be easy at any time to make an allowance for the very small portion of liquid alkali blended with the dew.'

The *ombrometer*, or *rain-gauge*, is a simple instrument, contrived to indicate the quantity or depth of rain which falls upon any spot. It has also been called an hyetometer. It is generally composed of a circular basin of iron lined with tin, soldered to the top of a vertical cylinder, which is contracted in some given proportion and close below. A small float is introduced, bearing a slender rod, distinguished by the corresponding divisions. Mr. Partington in his Manual of Natural and Experimental Philosophy, 2 vols. 8vo., thus describes a very useful one:—

'In the accompanying figure, it is seen to consist of a funnel *m*, attached to the top of a cylindrical vessel *b*. The bottom, *a c*, is furnished with a stop-cock to draw off the water when full, and also to open a communication with the graduated glass tube *d*. The tube is divided into parts, so as to register the quantity of water that enters the vessel, and so proportioned as to compensate for the difference between the sizes of funnel and cylinder.

'In fixing rain gauges,' says the above au-



thor, 'care should be taken that the rain may have free access to them, without being impeded or overshaded by any adjacent building. It may be proper also to add that, when the quantities of rain collected in them in different places are compared together, the instruments ought to be fixed at the same height above the ground at both places; because at different heights the quantities are always different, even in the same place. And hence, also, any register, or account of the rain in the gauge, ought to be accompanied with a note of the height at which the instrument is placed above the ground. Dalton found the rain of a gauge fifty yards high, in summer two-thirds, and in winter one-half as much as that of a gauge below. The above ingenious experimentalist adds, that a strong funnel, made of sheet-iron, tinned and painted, with a perpendicular rim, two or three inches high, fixed horizontally in a convenient frame, with a bottle under it to receive the rain, is sufficient for this purpose.'

Sect. VII.—Of the Optical Appearances and Delusions of the Atmosphere.

At once the most regular and most splendid of these is the *rainbow*, a phenomenon whose laws were calculated mathematically by Descartes, but not fully explained until the optical investigations of Sir Isaac Newton. 'In the formation of this meteor,' says the late Dr. Mason Good, 'it is necessary to observe that the ray which issues from the centre of the sun, and does not immediately, or perpendicularly, pass through the centre of the opposed globule of rain, must, upon the common principles of dioptrics, in consequence of its entering a transparent body of a different medium from the atmosphere itself, in a certain degree, be bent, deflected, or refracted from the right line in which it was proceeding; and hence, instead of passing out at the posterior part of the globule, immediately opposite to that at which it entered, it will be driven towards another limb, or marginal portion of the globule, and form an angular line co-equal to the obliquity with which it deviates from a right line on its entrance into the globule; just as a stake, or the oar of a boat, plunged obliquely into a river, appears to be broken, or deflected, from the point at which it enters the water. At this point the refracted ray, instead of passing out of the globule, suffers another deflection, but from a very different cause; for the ray of light having been thrown across a certain portion of the posterior chamber of the globule of rain, without permeating it, all behind its passage becomes necessarily a dark shade, while the globule itself forms an anterior and polished surface to it; whence a regular mirror is produced, and the ray is now reflected or thrown back from it, in the same manner as an incidental ray of light, or image, is reflected or thrown back from a looking-glass, or a deep and clear stream of water; both of which, like the globule thus situated, consist of nothing more than a dark shadow with a polished surface: the obliquity of its path, in the present instance, being precisely similar to that which it has previously suffered from refraction: the angular line of reflection being always co-equal with the angular line of incidence. It is hence obvious that the ray, or fascicle of parallel rays, which entered obliquely below the centre of the globule opposed to the centre of the sun, must be reflected obliquely above it; and as the same process necessarily takes place, but in an inversed order, with the antagonist ray, or fascicle of parallel rays that entered with the same degree of obliquity above it, it is also obvious that, from this double refracting and reflecting power of an individual globule of rain, situated as above described, an angle of light must be formed, from their antagonism alone, exhibiting the different colors of which they consist in a definitive order, according to the degree of their refrangibility; that the spread, or hypotheneuse of the angle must depend upon the diameter of the globule which produces it; and that its point being softened or obtunded to the eye, by the distance through which it is beheld, the angle must be converted into an arch. Hence, a beautiful and variegated rainbow must necessarily result from a few rays of light acted upon by a single globule of rain, situated as above, from the fact alone of its possessing the power of a binary mirror or prism.'

This writer accounts in a similar manner for the *mirage*, although it is chiefly to be noticed when the sky is clear and unclouded, and in the morning; but principally upon the coasts or banks of a large river See Optics

'The mirage seen by M. Crantz was on the shore of the Kookoernan Islands, near the Cape of Good Hope; it has often been traced at the back of the Isle of Wight; but the quarter in which, perhaps, it most frequently makes its appearance, is the Faro of Messina in Italy. In all these places, when the weather is perfectly calm, and consequently the sea almost without motion, the atmosphere, more especially in a dry and hot season, imbibes a considerable portion of the water upon which its lower stratum presses; and hence, in the night-time, becomes condensed and hazy. As the morning rises, however, and the sun-beams resume their vigor, the atmosphere once more rarefies, and re-acquires its transparency. If it rarefy equably, and homogeneously, every object beheld through it must necessarily be exhibited in its real proportion and figure: but it happens, occasionally, that in some parts of its texture it seems to be more closely interwoven than in others; and hence in its general expansion, veins, or striæ, like those often discovered in glass, make their appearance, of different densities and diameters. In this case, every stria, like every globule of rain, in consequence of the variation of its density from the common density of the atmosphere, becomes a refracting or a reflecting body; in other words, a prism, or a mirror, or both. If, then, a single globule of rain, properly disposed, be able to produce a phenomenon so marvellous as that of

the rainbow, what phenomena may we not expect, what variation, inversion, contortion, and grotesque and monstrous representation of images, beheld through a column of the atmosphere, intersected by so many aërial prisms of different densities, and mirrors of different surfaces, in which the catheti may be innumerable, and for ever varying? We may hence, moreover, readily trace the cause of an occasional duplication of images in the atmosphere, of a parhelion, and paraselene, or double sun, and double moon, from the reflection of these luminaries in an opposite part of the heavens, when they are a little above the horizon; as also of the very curious mirage remarked by M. Monge, in the hot and sandy desert between Alexandria and Cairo; in which, from an inverted image of the cœrulean sky intermixed with the ground scenery, the neighbouring villages appeared to be surrounded with the most beautiful sheeting of water, and to exist, like islands, in its liquid expanse, tantalizing the eye by an unfaithful represention of what was earnestly desired.'

'Our earliest enquiries,' says Mr. Leslie, 'led us to refer the origin of halos to the deflexion of light, or that property of the rays to bend and divide as they pass near the edge of a body. Thus the light admitted through a very narrow slit in a card, or a bit of tinfoil, spreads into bright colored fringes. The finer also is the slit, the broader are the fringes. A similar appearance is obtained by looking at the elongated flame of a candle through the delicate fibres of a feather, or even through the streaks of grease rubbed by the finger along a piece of glass. But, if a very small round hole be substituted for the slit, the fringes will change into colored rings. Thus, if a piece of tinfoil, punctured with the point of a needle, be held close to the eye, the sun will appear through it surrounded by a halo very near his disc, but spreading more in proportion as the hole is contracted. That ingenious artist, Mr. Troughton, constructed for us a slide of brass, and afterwards another of platina, perforated with a series of the finest conical holes, which were measured by his delicate micrometer. The purpose was to compare the angle subtended by the colored ring with the diameter of the perforation, it being inferred that an aqueous globule of the same dimension might, by the exterior deflexion of the solar rays, produce a similar halo. But our variable sky is very seldom fit for any refined optical experiment, and many delays happening to intervene, we could arrive at no very precise or certain result. We may state, however, as at least an approximation, that the globules of the diffuse vapor, which occasions the appearance of colored circles about the sun and moon, vary from the 5000th to the 50,000th part of an inch in diameter. When the halo approaches nearest to the luminous body, the largest globules are floating, and therefore the atmosphere is surcharged with humidity. Hence the justness of the vulgar remark, that a dense halo close to the moon portends rain.' Nearly the same theory is supported by Dr. Thomas Young, as we shall presently show.

Singular optical illusion in Baffin's Bay.—Among the remarkable illusions which arise from local variations in the density, and consequently in the refractive power of the atmosphere, we are not acquainted with any more interesting than one which was more than once observed by the officers on the late expedition to Baffin's Bay. Upon looking at the summits of distant mountains, they were surprised to observe a huge opening in them, as if they had been perforated, or an arch thrown from one to another. This effect arose from the apparent junction of the tops of the mountains, produced by a variation of density in some part of the atmosphere between the observer and the tops of the mountains, but which did not exist at a lower level, so as to affect the inferior parts of the mountains.

The *fata morgana* of the Mediterranean has been noticed by us in a distinct article. See Fata Morgana.

P. Minasi, whom we have quoted in the article referred to, enquires, in his able 'Dissertation,' into the etymology of Morgana. After various remarks, he thinks the opinion of those who derive this word, which is so foreign to the Roman idiom, from μωρος tristis, and γανοω lætitia afficio, is not far from the truth; considering the great exultation and joy this appearance produces in all ranks of people, who on its first commencement run hastily to the sea, exclaiming Morgana! Morgana! He remarks that he has himself seen this appearance three times, and that *he would rather behold it again than the most superb theatrical exhibition in the world.*

In the second chapter the author describes the city of Reggio, and the neighbouring coast of Calabria: by which he shows that all the objects which are exhibited in the Fata Morgana are derived from objects on shore.

In his third chapter, consisting of physical and astronomical observations, he affirms that the sea in the straits of Messina has the appearance of a large inclined speculum; that in the alternate current, or tide, which flows and returns in the straits for six hours each way, and is constantly attended by an opposite current along shore to the medium distance of about a mile and a half, there are many eddies and irregularities at the time of its change of direction: and that the Morgana usually appears at this period. Whence he enters into considerations of the relative situations of the sun and moon, which are necessary to afford high water at the proper time after sun-rise, as before described. It is high water, that is to say, the northern current ceases, at full and change, at nine o'clock. There is probably a small rise and fall, though the annotation to a large chart before me affirms that there is none.

In the fourth chapter, and subsequent part of the work, the author collects the opinion and relations of various writers on this subject; namely, Angelucci, Kircher, Scotus, and others; and he afterwards proceeds to account for the effects, by the supposed inclination of the surface of the sea, and its subdivision into different planes by the contrary eddies. We must refer the reader, however, for further particulars to the work itself.

The account furnished by Mr. Latham to the Philosophical Transactions, of a remarkable *atmospheric refraction*, by which the coast of Picardy became distinctly visible at Hastings, in 1798, we cannot here omit.

'July 26th, about five o'clock in the afternoon,' says this gentleman, 'while sitting in my dining-room at this place (Hastings) which is situated on the parade, close to the sea-shore, nearly fronting the south, my attention was excited by a great number of people running down to the sea-side. On enquiring the reason, I was informed that the coast of France was plainly to be distinguished with the naked eye. I immediately went down to the shore, and was surprised to find that, even without the assistance of a telescope, I could very plainly see the cliffs on the opposite coast; which, at the nearest part, are between forty and fifty miles distant, and are not to be discerned, from that low situation, by the aid of the best glasses. They appeared to be only a few miles off, and seemed to extend for some leagues along the coast. I pursued my walk along the shore to the eastward, close to the water's edge, conversing with the sailors and fishermen on the subject. At first they could not be persuaded of the reality of the appearance; but they soon became so thoroughly convinced, by the cliffs gradually appearing more elevated, and approaching nearer, as it were, that they pointed out, and named to me, the different places they had been accustomed to visit; such as the Bay, the Old Head or Man, the Windmill, &c., at Boulogne; St. Vallery, and other places on the coast of Picardy; which they afterwards confirmed, when they viewed them through their telescopes. Their observations were, that the places appeared as near as if they were sailing, at a small distance, into the harbours.

'Having indulged my curiosity on the shore for nearly an hour, during which the cliffs appeared to be at some times more bright and near, at others more faint and at a greater distance, but never out of sight, I went on the eastern cliff or hill, which is of a very considerable height, when a most beautiful scene presented itself to my view; for I could at once see Dungeness, Dover cliffs, and the French coast, all along from Calais, Boulogne, &c., to St. Vallery; and, as some of the fishermen affirmed, as far to the westward even as Dieppe. By the telescope, the French fishing-boats were plainly to be seen at anchor; and the different colors of the land on the heights, with the buildings, were perfectly discernible. This curious phenomenon continued in the highest splendor till past eight o'clock, though a black cloud totally obscured the face of the sun for some time, when it gradually vanished. I was assured, from every enquiry I could make, that so remarkable an instance of atmospherical refraction had never been witnessed by the oldest inhabitant of Hastings, nor by any of the numerous visitors come to the great annual fair. The day was extremely hot. I had no barometer with me, but suppose the mercury must have been high, as that and the three preceding days were remarkably fine and clear. To the best of my recollection, it was high water at Hastings about two o'clock P. M. Not a breath of wind was stirring the whole of the day; but the small pennons at the mast-heads of the fishing-boats in the harbour were in the morning at all points of the compass. I was, a few days afterwards, at Winchelsea, and at several places along the coast, where I was informed the above phenomenon had been equally visible. When I was on the eastern hill, the cape of land called Dungeness, which extends nearly two miles into the sea, and is about sixteen miles distant from Hastings, in a right line, appeared as if quite close to it; as did the fishing boats and other vessels, which were sailing between the two places; they were likewise magnified to a great degree.'

In another article in the same volume of the Philosophical Transactions (1798), Professor Vince observes, that he remarked a similar apparent approximation of the French coast to that of Ramsgate, in the summer of that year. 'Of two ships,' says he, 'which in different parts were equally sunk below the horizon, the inverted image of one would but just begin to appear, while that of the other would represent nearly the whole of the ship. But this I observed in general, that, as the ship gradually descended below the horizon, more of the image gradually appeared, and it ascended; and the contrary when the ships were ascending. On the horizon, in different parts, one ship would have a complete inverted image; another would have only a partial image; and a third would have no image at all. The images were in general extremely well defined; and frequently appeared as clear and sharp as the ships themselves, and of the same magnitude. Of the ships on this side of the horizon, no phenomena of this kind appeared. There was no fog on our coast; and the ships in the Downs and the South Foreland exhibited no uncommon appearances. The usual refraction at the same time was uncommonly great; for the tide was high, and at the very edge of the water I could see the cliffs at Calais a very considerable height above the horizon; whereas they are frequently not to be seen in clear weather from the high lands about the place. The French coast also appeared, both ways, to a much greater distance than I ever observed it at any other time, particularly towards the east, on which part also the unusual refraction was the strongest.

On the phenomena of *double refraction* Dr. Young has some excellent remarks in his Natural Philosophy, vol. i.

'The atmospherical phenomena,' says he, 'of rainbows and halos present us with examples of the spontaneous separation of colors by refraction. The rainbow is universally attributed to the refraction and reflection of the sun's rays, in the minute drops of falling rain or dew; and the halos, usually appearing in frosty atmospheres, are in all probability produced by the refraction of small triangular or hexagonal crystals of snow. It is only necessary, for the formation of a rainbow, that the sun should shine on a dense cloud, or a shower of rain, in a proper situation; or even on a number of minute drops of water, scattered by a brush or by a syringe, so that the light may reach the eye after having undergone a

certain angular deviation, by means of various refractions and reflections; and the drops so situated must necessarily be found somewhere in a conical surface, of which the eye is the vertex, and must present the appearance of an arch. The light, which is reflected by the external surface of a sphere, is scattered almost equally in all directions, setting aside the difference arising from the greater efficacy of oblique reflection; but when it first enters the drop, and is there reflected by its posterior surface, its deviation never exceeds a certain angle, which depends on the degree of refrangibility, and is, therefore, different for light of different colors: and, the density of the light being the greatest at the angle of greatest deviation, the appearance of a luminous arch is produced by the rays of each color at its appropriate distance. The rays which never enter the drops produce no other effect than to cause a brightness, or haziness, round the sun, where the reflection is the most oblique: those which are once reflected within the drop exhibit the common internal or primary rainbow, at the distance of about 41° from the point opposite to the sun; those which are twice reflected, the external or secondary rainbow, of 52°; and if the effect of the light, three times reflected, were sufficiently powerful, it would appear at the distance of about 42° from the sun. The colors of both rainbows encroach considerably on each other; for each point of the sun may be considered as affording a distinct arch of each color, and the whole disk as producing an arch about half a degree in breadth for each kind of light; so that the arrangement nearly resembles that of the common mixed spectrum. There is, however, another cause of a further mixture of colors: the arch of any single color, which belongs to any point of the sun, is accurately defined on one side only, while on the other it becomes gradually fainter, the breadth of the first minute containing about five times as much light as a minute at the distance of a quarter of a degree: the abrupt termination is on the side of the red, that is, without the inner bow, and within the outer; so that, for this reason, the order of colors partakes, in some degree, of the nature of the red termination of a broad beam of light seen through a prism; but it is more or less affected by this cause, on account of some circumstances, which will be explained when we examine the supernumerary rainbows, which sometimes accompany the bows more commonly observed. A lunar rainbow is much more rarely seen than a solar one, but its colors differ little, except in intensity, from those of the common rainbow.

'In the highest northern latitudes, where the air is commonly loaded with frozen particles, the sun and moon usually appear surrounded by halos, or colored circles, at the distances of about 22° and 46° from their centres; this appearance is also frequently observed in other climates, especially in the colder months, and in the light clouds which float in the highest regions of the air. The halos are usually attended by a horizontal white circle, with brighter spots, or parhelia, near their intersections with this circle, and with portions of inverted arches of various curvatures; the horizontal circle has also sometimes anthelia, or bright spots, nearly opposite to the sun. These phenomena have usually been attributed to the effect of spherical particles of hail, each having a central opaque portion of a certain magnitude, mixed with oblong particles, of a determinate form, and floating with a certain constant obliquity to the horizon. But all these arbitrary suppositions, which were imagined by Huygens, are in themselves extremely complicated and improbable, and are wholly unauthorised by observation. A much simpler, and more natural, as well as more accurate explanation, which was suggested at an earlier period by Mariotte, had long been wholly forgotten, until the same idea occurred to me, without any previous knowledge of what Mariotte had done. The natural tendency of water to crystallise, in freezing, at an angle of 60°, is sufficiently established, to allow us to assume this as the constant angle of the elementary crystals of snow, which are probably either triangular or hexagonal prisms: the deviation produced by such a prism differs very little from the observed angle at which the first circle is usually seen; and all the principal phenomena which attend this circle may be explained, by supposing the axis of the crystals to assume a vertical or a horizontal position, in consequence of the operation of gravity: thus the parhelia, which are sometimes a little more distant from the sun than the halo, are attributed by Mariotte to the refraction of the prisms, which are situated vertically, and produce a greater deviation, on account of the obliquity of the rays of light with respect to their axis. The horizontal circle may be deduced from the reflection, or even the repeated refractions, of the vertical facets; the anthelia from two refractions with an intermediate reflection; and the inverted arch from the increase of the deviation, in the light passing obliquely, through prisms lying in a horizontal position. The external circle may be attributed either to two successive refractions through different prisms, or, with greater probability, as Mr. Cavendish has suggested to me, to the effect of the rectangular terminations of the single crystals. The appearance of colors, in halos, is nearly the same as in rainbows, but less distinct; the red being nearest to the luminary, and the whole halo being externally very ill defined. From the observed magnitude of these halos, I had concluded that the refractive power of ice must be materially less than that of water, although some authors had asserted that this was greater: and Dr. Wollaston afterwards fully confirmed this conclusion, by means of the very accurate instrument which has already been described; his measurement agreeing precisely with the mean of the best observations on these halos, so that ice must be considered as the least refractive of any known substance not aëriform.

'Sometimes the figures of halos and parhelia are so extremely complicated as to defy all attempts to account for the formation of their different parts; but, if we examine the representations which have been given by various authors of the multiplicity of capricious forms frequently assumed by the flakes of snow, we shall see no

reason to think them inadequate to the production of all these appearances.

In his second volume Dr. Young has given an abstract of Dr. Wollaston's observations on the quantity of horizontal refraction. It is as follows:—

'Dr. Wollaston notices Mr. Monge's Memoir on the Mirage, observed in Egypt, as containing facts which fully agree with his own theory formerly published. From his observations on the degree of refraction produced by the air, near the surface of the Thames, it appears that the variations derived from changes of temperature and moisture in the atmosphere are by no means calculable; but that a practical correction may be obtained, which, for nautical uses, may supersede the necessity of such a calculation. Dr. Wollaston first observed an image of an oar at a distance of about a mile, which was evidently caused by refraction, and, when he placed his eye near the water, the lower part of distant objects was hidden, as if by a curvature of the surface. This was at a time when a continuation of hot weather had been succeeded by a colder day, and the water was sensibly warmer than the atmosphere above it. He afterwards procured a telescope, with a plane speculum placed obliquely before its object glass, and provided with a micrometer, for measuring the angular depression of the image of a distant oar, or other oblique object; this was sometimes greater when the object glass was within an inch or two of the water, and sometimes when at the height of a foot or two. The greatest angle observed was somewhat more than nine minutes, when the air was at 50°, and the water at 63°; in general the dryness of the air lessened the effect, probably by producing evaporation; but sometimes the refraction was considerable, notwithstanding the air was dry. Dr. Wollaston has observed but one instance which appeared to encourage the idea, that the solution of water in the atmosphere may diminish its refractive power. In order to correct the error to which nautical observations may be liable, from the depression of the apparent horizon, in consequence of such a refraction, or from its elevation in contrary circumstances; and at the same time to make a proper correction for the dip, Dr. Wollaston recommends that the whole vertical angle, between two opposite points of the horizon, be measured by the back observation, either before or after taking an altitude: and that half its excess above 180° be taken for the dip: or, if there be any doubt respecting the adjustment of the instrument, that it be reversed, so as to measure the angle below the horizon, and that one-fourth of the difference of the two angles, thus determined, be taken as extremely near to the true dip. It is indeed possible that the refraction may be somewhat different at different parts of the surface; but Dr. Wollaston is of opinion that this can rarely happen, except in the neighbourhood of land.'

To these speculations on the optical phenomena of the atmosphere, we may consistently add an abstract of the remarks of professor Hansteen, in the Christiania Journal of Natural History, on the Aurora Borealis and the Polar Fogs. It will be observed that he avails himself of several of the observations of our late navigators in the Polar regions.

'With us,' he says, 'it is well known that the aurora borealis presents itself to view in the following manner:—In the N.N.W. appears a luminous arch, the convex side of which is turned to the zenith, and the extremities of which bend towards the horizon. That part of the circle of the horizon which lies between its extremities forms a chord of the arch. The segment of the circle between the arch and the horizon is, for the most part, darker than the rest of the sky; sometimes black, sometimes dark-gray. The farther you advance towards the north, this colored segment becomes less dark; and, in the highest latitudes, it becomes altogether undistinguishable. The highest point of the arch, at least in latitudes not very high, is almost always found in the magnetic meridian, that vertical plane which passes through the magnetic pole. In the North American States, where the westerly variation of the needle is only two degrees, the same luminous arch is seen, but its highest point lies due north. According to Scoresby's observations on the east coast of Greenland, in lat. 65° N., the arch of the aurora borealis lies from north to south, in such a manner that its highest point is either to the east or west, as the arch lies on the one side or the other of the zenith. This agrees with the remarks of the missionary, Andrew Ginge, on the aurora borealis, in the colony of Good Hope, in Greenland (lat. 64° 10′ 5″); with this difference only, that the arch commonly appears low in the east or south-east, and more seldom approaches near to the zenith. He describes in the following manner such an arch, as seen on the 12th December, 1786. 'At half-past four, P. M., the first faint flashes of the aurora borealis arose from the east, which a quarter of an hour after reached the zenith, and from that shot out on all sides. Soon after, these were converted into an arch, which went through the zenith, and almost touched the horizon in the north and south. This arch was white, and so brilliant that it lighted up Baals River, which is a mile broad. At seven P. M. the declination had decreased, from mid-day, from 50° 57′ to 50° 37′, that is, 20′. At half-past eight the arch disappeared, and in the south was seen a comb with its teeth upwards. At that time the declination was 50° 20′,' &c.

From the foregoing observations, it is easy to see that this arch must be a part of a whole luminous ring, hovering over the surface of the earth at a considerable height, of which every observer sees his own portion. We may give an explanation of this by means of the hour-circle on a globe. Suppose a little insect creeping round the globe in the sixtieth parallel, it will only see a small part of the ring, as the largest portion of it will be concealed by the globe which forms the insect's horizon. The highest part of the arch which in this case it can see will be due north. If it approach nearer to the ring, it will see a larger portion of it; and, when it is close under its edge, this will appear to be in the zenith. If it come nearer the pole, and within the ring, the nearest and highest part of the ring will be seen to the south, just as the

ring of the aurora borealis was seen at Good Hope. Now, were the pole of the earth, or rather a point of its lengthened axis, the centre of the ring of the aurora borealis, the highest point of the arch would be seen every where in the true meridian, or due north. But, as this is not the case, since, with us, the highest point of the arch is seen about 20° west of due north, in North America it is seen due north, and at Good Hope, in Greenland, to the east, it follows that the centre of the ring must lie about from 20° to 30° from the pole of the earth, in a meridian passing through the states of North America. And since the arch is sometimes seen in the zenith near Iceland, and often stretches so far to the south as to pass the zenith, both here, in Christiania and in Copenhagen, and even in more southerly regions, it follows that the radius of the ring of the aurora borealis may extend from 20° to 40° and above. It is easy now to perceive in what manner the arch of the aurora borealis will appear in different meridians. If it be viewed from a point lying in the same meridian with its centre, its highest point will appear due north; and, if this rise so high as to pass through the zenith, its extremities will terminate in the east and west. If, again, it be viewed from a point lying eastward of the meridian of the ring, as with us in Europe, then the highest point of the arch will move to the west of the meridian, and the farther the more you advance to the north, till you come to the same latitude with the centre of the ring, between 60° and 70°. Here the highest point of the arch will lie due west; and, if the ring extend so far as to pass through the observer's zenith, it will go from north to south, that is, it will be parallel with the meridian.

'Such was the case with regard to the arch seen by captain Scoresby on the 15th of April, in lat. 64° 41' If the place of the observer be within the circumference of the ring of the aurora borealis, as is the case with the colonies in the western districts of Greenland, the arch will be seen to the south, provided the observer be south from its centre, and to the east, if he be east from it. These rules may be shortly expressed in the following formula. If the observer be on the outside of the ring of the aurora borealis, he will see the highest point of the arch in the same direction with the centre of the ring: if he be within the ring, the highest point of the arch will be seen in the direction opposite to that of the centre of the ring. That the centre of the ring of the aurora borealis does not coincide with the north pole of the earth is a very remarkable fact. This centre coincides as near as possible with the magnetic pole in North America, the place of which we have determined in the first volume of this Journal (Christiania Mag. of Nat. Hist. p. 19). From this we are led to suppose that there must be some connexion between the aurora borealis and the magnetism of the earth.

'This conjecture is strengthened by the observations of captain Cook with respect to the aurora australis. When that celebrated navigator, on his second voyage, was sailing round the south pole, he often saw, in the southern parts of the Indian Sea, arches of the aurora australis, the highest point of which always lay to the south-east, so long as the ship sailed between the meridian of the Indian peninsula and the parallel of 60°. In that region the variation of the compass is between 30° and 40° W. The highest point of the arch of the aurora australis coincides here too with the direction of the needle. But as soon as he approached the meridian of Van Diemen's Land, where the variation of the compass disappears, the highest point of the arch of the aurora australis was found, too, in the true meridian. From this it appears that the centre of the ring of the aurora australis likewise lies at a considerable distance, from 30° to 40°, from the south pole of the earth, and in a meridian which passes through New Holland. And here, too, we have shown in the first volume, is the south magnetic pole to be found. He afterwards infers, That the polar lights spring from four points on the surface of the earth, which, so far as we have hitherto been able to determine, coincide with the magnetic poles of the earth. The larger luminous ring is formed round the two opposite poles of the stronger magnetic axis in North America and New Holland. Whether a similar ring, as full and as regular, be formed round the poles of the weaker axis, in Siberia and Terra del Fuego, is a matter which, from the few observations which we are able to collect, cannot yet be so well ascertained. The arch of the polar light is seldom seen without luminous beams shooting out from it. From the side of the arch turned away from the pole, beams or rather columns of light dart forth in a direction nearly perpendicular to the arch, and ascend towards the zenith. If these beams are so long as to pass a considerable way beyond the zenith, towards the south, they form, in the neighbourhood of the zenith, a kind of corona or glory, which seems to be the point of their union. This corona lies from 15° to 20° S. of the zenith, in such a situation, that if we suppose a vertical plane passing through the highest point of the arch, which with us lies about 20° W. from the meridian, and produced so as to pass through the zenith, it will come exactly upon the middle of the corona. And it is a very remarkable circumstance, that the distance of this corona from the southern horizon is exactly equal to the inclination of the needle at the place: so that the south pole of the needle points directly to the centre of the corona.

'The *formation* of the corona,' he observes, 'can only be explained by supposing that the luminous columns shoot from the surface of the earth in a direction parallel to the inclination of the needle, and to the direction of the earth's magnetism; that they first become luminous when they pass out of our atmosphere; while, on passing through it, they have the opposite effect of rendering it opaque. By this we can explain the dark segment which appears under the arch; and also this remarkable fact, that, while the aurora borealis is in play, the sky, which is now perfectly transparent, may, in less that a minute of time, be covered with an almost impenetrable veil, which again may vanish in a time as short, —a circumstance which, in our northern regions,

may very unexpectedly derange many an astronomical observation. By this supposition, too, we can explain the dark-colored streaks of the aurora borealis, which I myself have frequently observed, and which are mentioned by several persons who have described these lights in Norway. If we turn the eye towards the magnetic zenith (if I may be allowed to give this name to that point in the heavens to which the higher, or, with us, the southern pole of the needle points), we here see the luminous columns from the end; and, as they are at a considerable distance from one another, in this situation the eye perceives the blue arch of the heavens between them. In all other parts of the sky we see the luminous columns obliquely; so that the one covers the other, which consequently gives them the appearance of beams darting from the arch, connected in one body.

'I have already hinted,' says the professor, 'that there must be some connexion between the aurora borealis and the magnetism of the earth. Besides the reasons which may be derived from the facts already mentioned, I mean, that the centres of the luminous rings coincide with the four magnetic poles; also that the luminous columns shoot parallel to the medium direction of the magnetic powers at any one place; and that they, beyond all doubt, follow the laws of repulsion of the magnetic powers, and, consequently, themselves are magnetic,—there are many other reasons as strong, if not stronger, of which I shall briefly mention only the most important.

'1. When the aurora borealis is vivid, the horizontal magnet becomes restless, varies in a few minutes from three, four, to five degrees from its ordinary place, and sometimes gets into a quivering motion, which shows that, at that time, the magnetic powers of the earth are in a state of great agitation. 2. A short time before the aurora borealis appears, the intensity of the magnetism of the earth is apt to rise to an uncommon height; but so soon as the aurora borealis begins, in proportion as its force increases, the intensity of the magnetism of the earth decreases, recovering its former strength by degrees, often not till the end of twenty-four hours. These changes are sometimes so sudden, that I once observed a considerable difference in the space of from two to three minutes. (The professor here details an experiment made with a fine magnetic needle, suspended by the thread of a silkworm. He counted its vibrations to the amount of 360; and dividing this number into equal portions, and comparing by a chronometer the time occupied by each portion, he found a difference in the number of vibrations performed in the same time, far exceeding any which could arise from the inaccuracy of the observation, proving a difference during the time of the experiment in the intensity of the magnetic force). From this, he says, it seems to follow, that the polar lights are the effect of an uncommonly high magnetic intensity, which intensity lets itself off, as it were, by the polar lights, and thus sinks under its common strength. 3. During the time of a powerful display of the aurora borealis, Mallet and others have found no uncommon strength of electricity in the air, which seems to disprove the hypothesis of Franklin. 4. The Rev. Mr. Steenbuck, who was the editor, and, in a great measure, the author of the Description of the Kingdom of Norway, published under the name of Jessen, and who was himself born in the province of Trondheim, relates, concerning the arch of the aurora borealis, that, according to the accounts of old people, this arch was wont to appear lower on the horizon in Nordland, and nearer to the true north; that, since these times, it has risen higher in the sky, and removed from the meridian towards the west. This agrees entirely with the change of place of the North American magnetic pole, by which it lies somewhat nearer to us, and in a plane which forms a larger angle with the meridian. 5. The Swedish naturalist Wilcke has remarked, that, during a vivid borealis, the corona sometimes changes its place, moving backward and forward several degrees. But, since the place of the corona is determined by the angle formed by the luminous columns with the surface of the earth, it is evident that the angle must likewise change. And, in such cases, he observed, that the inclination of the needle altered in a similar manner, so that, moving up and down, it always pointed to the centre of the corona. A change in the direction of the earth's magnetism produces also a change in the direction of the luminous columns. The perpendicular height of the arch of the aurora borealis above the surface of the earth is to be computed from its height above the horizon, observed at two different places, which lie at a considerable distance from one another, nearly in the same meridian. From a number of those arches, the cotemporaneous height of which was observed at Rome, Paris, Copenhagen, Stockholm, and other places, Mr. Mairan has found, that the ring of the polar lights above the surface of the earth almost always exceeds 100 geographical miles. The luminous columns of which the shooting beams consist have, in all probability, the same height.

'Hudson's Bay and Straits, Baffin's Bay, and the sea around Greenland, are distinguished, in a remarkable manner, by a thick fog, which almost constantly prevails there. Captain Parry suffered much inconvenience from this fog, when he got into Lancaster Sound, and into the straits discovered by him, which he calls Barrow's Straits; and the more on this account that the compass ceased here to have any fixed direction, or, as the sailors say, it wandered. Lieutenant (now captain) Franklin, too, if I remember right, experienced the same thing on his land expedition, along the northern coasts of America on the Polar Sea. Captain William Scoresby's explanation of the origin of this fog seems very admissible, though there may be found other circumstances concurring to the production of the same effect. A similar thick fog prevails likewise in the sea which surrounds Terra del Fuego. I have mentioned already, that Don Antonio de Ulloa says, in his letter to Mairan, that in sailing round cape Horn he found only a few moments when he could obtain a slight glance of the sky. As the same fog is neither so thick nor so constant in other places

of the same latitude, in Behring's Straits, for instance, or south from the Cape of Good Hope, it is not impossible that the streaming of the magnetic power, or of the polar lights, here, too, played their part. It is known by experience that, while these streamers are flowing, the sky has a tendency to become opaque and misty. While the polar lights pass through the air, they must have the effect, in penetrating the watery vapors existing in it in a transparent state, of taking from them their heat, and thereby rendering them opaque. When a solid body passes over into a fluid, or a fluid body into a gaseous state, it acquires a greater quantity of heat; and, in acquiring it, thus robs every surrounding body with which it comes in contact of a part of what they contain. It is thus, in warm climates, they cool vessels by surrounding them with wet cloths; so that the evaporation of the water, in the form of steam, deprives the vessel of a great portion of its heat. In the same manner has nature provided for the cooling of the animal body, in the time of excessive heat, by the increased perspiration, the evaporation of which preserves it in an almost unchanged temperature. Now, as the polar lights are an expansible substance, which in regions surrounding the magnetic poles is continually issuing from the surface of the earth, even at times when we who lie at a distance from these points perceive nothing of this, it may be conceived that this stream, in passing through the atmosphere, is continually lowering its temperature, and thus, in decomposing the watery vapors, producing fog. In this manner, too, may be explained another well-known phenomenon. It might be expected that, in the same parallels, the mean temperature would be every where nearly the same—as the length of the day, and the height of the sun, depend alone on the latitude. But this is by no means the case. In that parallel which passes the sixtieth degree of north latitude, the temperature is the lowest in Hudson's Bay, and at the south point of Greenland. As we approach the coasts of Norway it rises, and in Christiania and Stockholm is about + 5°. In Petersburgh it has begun to descend, and the farther we advance to the east it becomes the lower; so that a Siberian cold has become a proverbial expression. Although Cape Horn lies in the fifty-sixth degree of south latitude, that is about the same latitude with Copenhagen, the cold there is intolerable; and yet at other points of the same parallel it is less. It seems also pretty well proved, that, in one and the same parallel, the mean temperature is least in the meridians which pass through the magnetic poles. Count Humboldt has rendered this distribution of temperatures subject, in a very remarkable manner, to our observation, by connecting, on a chart, all the points where the mean temperature is the same, by a sort of curve lines, which he calls Isothermic Lines. These lines are by no means parallel to the equator, as might be supposed, but remove to the greatest distance from it in the Atlantic Ocean, sinking again both in America and in the eastern hemisphere. Comparing this chart with the lines of the inclination of the needle, in the seventh table of my Magnetismus der Erde, it will be found that these different lines follow very much the same course; a circumstance which is to be explained in this manner: a greater inclination of the needle proves a smaller distance from the magnetic poles, and, consequently, from the place from which the polar lights issue. But, if this meteor has any influence on the temperature, the mean temperature in the same parallel must decrease as the inclination increases; and, consequently, the isothermic lines have the same curvature as the lines of inclination.

'It is a matter of experience perfectly well-known here in the north, which I have found confirmed by the observation of a good many years, that the aurora borealis is generally accompanied by strong biting cold. When a sudden cold succeeds a milder day, it is often accompanied for the first two evenings by the aurora borealis, and likewise by a considerable increase of magnetic intensity. These three phenomena are for the most part contemporaneous; but, where they are not so, experience has taught me, with considerable certainty, to view the one as a near forerunner of the other. The magnetic powers seem thus to act a part in meteorology hitherto unknown. There are, perhaps, various other powers unseen by us, operating in the great chemical laboratory of this globe. The possibility of this ought to teach the prognosticators of the weather some diffidence, when they imagine that, from the situation of the heavenly bodies, or a few circumstances perhaps of little influence, they can foresee its approaching changes; while these are the result of the general powers of the globe, acting from the centre to the surface, and from pole to pole, excited by the light of the sun and moon, and modified in countless ways, by local circumstances of the most different nature. Is it so, then, that the polar lights have a certain connexion with the magnetism of the earth, and the diminution of temperature with the polar lights and a higher magnetic intensity? We are then, perhaps, prepared to explain the seemingly permanent changes of climate in certain northern regions of the globe, if these changes can be actually proved to have taken place. But the accurate observation of temperature by the thermometer is still too recent a discovery, and the range of thermometrical observations in the same place too limited, to enable us to determine this point with absolute certainty. In the mean time, the surrounding of the east coast of Greenland with ice, for a number of ages, is a very remarkable fact. The magnetic pole in North America approaches slowly towards the east; and ought, therefore, if the foregoing possibilities have any reality, in the succession of ages, to surround the northern part of our peninsula with the same barrier, by which it has for ages shut out the east coast of Greenland from all participation in the commotions of Europe. However desirable this might be, in some respects, we cannot help wishing, on other accounts, that this prediction may turn out like other prognostications of the weather.'

Sect. VIII.—Of the Prester or Water-spout.

Gassendi contended that the prester of the ancients was a mere tornado or whirlwind; but

this was before the nature, or even the existence, of electricity, as a definite power, had been accurately ascertained; and to prove that this is an error, it is only necessary to quote the description of the prester, as given by Lucretius, and to follow up the quotation with the explanation of his translator, Dr. Good, by which it will abundantly appear that the prester, like the spout of the present day, was regarded as both a sea and land meteor, or in other words as filled with water, and without water; the term being more properly applied to the former, and the latter being correctly regarded and called a mimic, or imitative prester; in reality the fiery whirlwind or hurricane.

The passage we advert to is as follows: lib. vi. 422.

Quod super est, facul est ex hiis cognoscere rebus,
Πρηστηρας Graiei quos ab re nominitarunt,
In mare quâ missei veniant ratione superne.—&c. &c.

Hence, with much ease, the meteor may we trace
Termed, from its essence, PRESTER by the GREEKS,
That oft from heaven wide hovers o'er the deep,
Like a vast column, gradual from the skies,
Prone o'er the waves, descends it; the vext tide
Boiling amain beneath its mighty whirl,
And with destruction sure the stoutest ship
Threat'ning that dares the boist'rous scene approach.
Thus solve th' appearance; that the maniac wind,
In cloud tempestuous pent, when unempower'd
To burst its bondage, oft the cloud itself
Stretches cylindric, like a spiral tube
From heaven forced gradual downwards to the deep;
As though some viewless hand, its frame transpierced,
With outspread palm had thrust it from above.
This, when at length, the captived tempest rends,
Forth flies it, fiery, o'er the main, and high
Boils from its base th' exaggerated tide.
For, as the cone descends, from every point
A dread tornado lashes it without,
In gyre perpetual, through its total fall:
Till, ocean gained, the congregated storm
Gives its full fury to th' uplifted waves,
Tortured and torn, loud howling midst the fray.
Oft, too, the whirlwind from the clouds around
Fritters some fragments, and itself involves
Deep in a cloudy pellicle, and close
Mimics the prester, lengthening slow from heaven;
Till, earth attained, th' involving web abrupt
Bursts, and the whirlwind vomits and the storm.
Yet, as on earth the mountains' pointed tops
Break oft the texture, tubes like these, at land
Far rarer form than o'er the marble main.

The translator's note upon this passage, in exposition of his author, is as follows, and we give it as affording a clear explanation of the nature and properties of this singular meteor:—

'Having discussed the phenomenon of thunder and lightning, he now proceeds to consider those of the water-spout, and the hurricane; and it is truly curious to observe how minutely he concurs with the philosophy of the present day, in regarding them as meteors of a similar nature and origin. Prester, indeed, as our poet informs us, is a Greek word, signifying a fiery or inflammatory intumescence; and such, he asserts, is the essence of which this meteor (the water-spout) consists: whence it is obvious that the term ventus, or wind, applied to it immediately afterwards, is employed generically, to express an elastic gas or ether, for which Lucretius found no definite expression in his own language, rather than the nature of wind properly so called. It is an igneous or fiery aura, not indeed in the open act of combustion, but composed of the finest and most minute particles of a peculiar species of elementary fire, which, in a more concentrated form, would necessarily become luminous and burning.

'Gassendi, indeed, contends, that the Epicurean prester is not an igneous meteor, but a mere vortex of elastic air. But there can be no doubt of his being mistaken; for Lucretius not only employs a term to which fire, in some modification or other, either elementary or combined, is necessarily attached, but refers us in the opening of the discussion, by way of explanation, to the constituent particles of lightning, which, he expressly declares, consist of the very finest and most attenuate fiery atoms.

'Fiery, too, and of the common essence of lightning, is this meteor asserted to be, by the philosophy of the present day. For it is regarded as an electrical phenomenon, as, indeed, is almost every atmospherical meteor, as well as a great variety that are subterraneous. In describing the powers and operation of the thunder-cloud, in note on v. 256 above, I have noticed its wonderful faculty of attracting, with almost instantaneous speed, the lighter and adscititious clouds in its vicinity, as I have also its submission to the still more strongly attractive power of that part of the earth which lies immediately beneath it, in a state of negative electricity, evidenced by its dipping downwards either in ragged and multiform fragments, or, where the film of the cloud is tenser, in more regular and unbroken protuberances. Retaining then these simple facts in our recollection, it will not be difficult to account for the phenomenon of the prester, or water-spout, upon the principles of the electric theory.

'A thunder-cloud, or cloud filled with electric matter, is first noticed to appear at sea in a sky so serene as to be totally destitute of adscititious clouds, and in an atmosphere so dry as to be possessed of very little and impalpable vapor. Such is the general appearance of the horizon on the commencement of the water-spout. In such a situation a thunder-storm cannot be the result, for want of the confederate assistance of additional clouds and vapors: but, from the circumstances enumerated above, a very considerable portion of mutual attraction must take place between this isolated cloud, and the portion of the sea immediately beneath it, more especially if the sea be at this time negatively electrified, or destitute of the electric power of which the cloud has a vast surplus. From this mutual attraction, the water directly under the cloud will become protuberant upwards, rising like a hill towards the cloud above, which, in the phenomenon we are now describing, it always does, and the cloud above will become protuberant downwards, elongating itself towards the elevated portion of water beneath. If, in this action of straining, the texture of the cloud be very slight, it will burst into a thousand fragments, and the electric matter contained within it will

WATER SPOUT SEEN NEAR THE LIPARI ISLANDS

London Published by Thomas Tegg 73 Cheapside.

J. Shury sculp

be quietly dissipated, or attracted to the ocean; but, if it be stronger and more viscous, it will continue to stretch without bursting; and, like every other elastic substance, the more it stretches, the narrower will be the projected tube. Such, to the mariner, is the actual apperance of the column of the water-spout, precisely resembling a speaking trumpet, with its base or broader part uppermost. When the mouth of this projected tube touches the rising hillock of water, if the attraction of the negatively electrified ocean be superior, the electric aura, we may naturally suppose, will be drawn downwards, and the empty cloud be totally dissipated; but, as will generally occur in the case of a positive force applied to a negative, if the attraction of the electric cloud prove victorious, it will continue to suck up the rising hillock of water till it is altogether sated, and can hold no more. At this time the cloud must necessarily burst from its own weight and distention, and in proportion to its size, and the deluge of water and electricity it discharges, will be the mischief produced. It is said that it may occasionally be rent, at a distance, by making a violent noise on board the ship in which it is perceived by files, saws, or other discordant instruments; and, certainly, whatever will tend to agitate the air in any considerable degree, affords some prospect of breaking the cloudy film, and thus dispersing the meteor; but the more ordinary method of shooting at it from guns of a large calibre, gives a much stronger, and, indeed, almost certain chance of success; for no mechanical power can agitate the surrounding atmosphere by any means so forcibly as the report of a large cannon; and, if it be loaded with ball, it will give a double prospect of discharging the contents of this tremendous spectacle.'

Upon that part of the description which relates to the mimic prester, Dr. Good observes as follows: 'Lucretius here alludes to meteors of a similar description, but not quite so tremendous in their effect: and is generally supposed to refer to the hurricane, or, as the Greeks termed it, εκνεφια; which is equally an electrical phenomenon, and may be regarded as a prester occurring on land, and consequently as an electric cloud filled with elastic air only, or other vapors received from the atmosphere, and not often with water. It is produced in the same manner as the sea-prester, has the same kind of elongated tube reaching towards the negatively electrified portion of the earth by which it is attracted, and is accompanied, previous to its bursting, by a similar tornado of external air. This elongated tube, as well as the substance of the cloud itself, in the time of Shakspeare, was supposed to have its film or fibres condensed and rendered firmer by the operation of the rays of the sun; but there is no necessity for such an idea:—

——the dreadful spout
Which shipmen do the hurricano call,
Constringed in mass by the almighty sun.
Troilus and Cressida.

'We may account for the phenomenon in this manner: that the thirsty cloud, in consequence of a more elevated position than ordinary in the atmosphere, at the time it commences its attraction with the water below, satiates and distends itself, by means of its proboscis, with absorbed air alone, prior to the actual contact of such proboscis with the hillock of rising water; so that, by the time this elongating spout extends to the attracted hillock, it is totally incapable of containing any thing farther.'

Cavallo supposes that electricity is rather a consequence than a cause of water-spouts; and notices that they sometimes vanish and reappear. Dr. Franklin conceived that a vacuum is made by the rotatory motion of the ascending air, as when water is running through a tunnel, and that the water of the sea is thus raised. But it is justly observed, by Dr. Young, that no such cause as this could do more than produce a slight rarefication of the air, much less raise the water to above thirty or forty feet. At the same time the force of the wind thus excited might carry up much water in detached drops, as it is really observed to exist in water-spouts. Dr. Young remarks moreover, in another passage, that the phenomena of water-spouts, if not of electrical origin, appear to have some connexion with electrical causes. A water-spout generally consists of large drops, like a dense rain, much agitated, and descending or ascending with a spiral motion, at the same time that the whole spout is carried along horizontally, accompanied in general by a sound like that of the dashing of waves. Spouts are sometimes, although rarely, observed on shore, but generally in the neighbourhood of water. They are commonly largest above; sometimes two cones project, the one from a cloud, the other from the sea below it, to meet each other, the junction being accompanied by a flash of lightning: and, when the whole spout has exhibited a luminous appearance, it has perhaps served to conduct electricity slowly from the clouds to the earth. Some of these circumstances may be explained by considering the spout as a whirlwind, carrying up drops of water, which it has separated from the surface of the waves; and the remainder may perhaps be deduced from the co-operation of electricity, already existing in a neighbouring cloud.

One of the best accounts of the appearance of the genuine prester is given by Mr. Maxwell in the Edinburgh Philosophical Journal.

During several voyages to Congo, he frequently witnessed this interesting phenomenon; and in a drawing in his Journal, from which fig. 1 of our plate METEOROLOGY is copied after the Edinburgh Philosophical Journal, he has represented the different states of a water-spout, as they most commonly occur.

'At their first formation they appear,' he says, 'as at A, where the black cloud drops from a level surface into a conical form, before the disturbance at the surface of the sea, as shown at D, is observed. The effect produced at D is like that of a smoking furnace. The black conical cloud now continues to descend, as shown at B, till it almost reaches the surface of the sea, and the smoke-like appearance rises higher and higher till it forms a union with the cloud from which the spout appears to be suspended. In this si-

tuation it is said to put on its most terrific appearance to the mariners who have the misfortune to be in its neighbourhood. When the spout begins to disperse it assumes the appearance shown at C. The black cloud generally draws itself up in a ragged form, but leaves a thin transparent tube C E, which reaches to the water where the smoke-like commotion still prevails. Mr. Maxwell observed at this time in the upper part of the tube a very curious motion.'

This fact, of the existence of a transparent tube, confirms Mr. Alexander Stewart's description in the Philosophical Transactions, of the water-spouts which he saw in the Mediterranean in 1701. 'It was observable of all of them,' says he, 'but chiefly of the large pillar, that towards the end it began to appear like a hollow canal, only black in the borders, but white in the middle; and, though at first it was altogether black and opaque, yet one could very distinctly perceive the sea-water to fly up along the middle of this canal as smoke does up a chimney, and that with great swiftness, and a very perceptible motion; and then, soon after, the spout or canal burst in the middle, and disappeared by little and little; the boiling up and pillar-like form of the sea water continuing always the last, even for some considerable time after the spout disappeared, and perhaps till the spout appeared again, or reformed itself, which it commonly did in the same place as before, breaking and forming itself again several times in a quarter or half an hour.' --Philosophical Transactions 1702, p. 1077.

We copy the following from the Journal of the Royal Institution.

Extract of a letter from William Ricketts, esq. Captain in the Royal Navy, to the Right Hon. Sir Joseph Banks, Bart. &c. &c.

In the month of July, 1800, captain Ricketts was suddenly called on deck, on account of the rapid approach of a water-spout among the Lipari Islands; it had the appearance of a viscid fluid, tapering in its descent, proceeding from the cloud to join the sea; it moved at the rate of about two miles an hour, with a loud sound of rain; it passed the stern of the ship, and wetted the after-part of the mainsail; hence captain Ricketts concluded that water-spouts were not continuous columns of water; and subsequent observations confirmed the opinion. See plate METEOROLOGY, fig. 2.

In November, 1801, about twenty miles from Trieste, a water-spout was seen eight miles to the southward; round its lower extremity was a mist, about twelve feet high, nearly of the form of an Ionian capital, with very large volutes, the spout resting obliquely on its crown. At some distance from this spout the sea began to be agitated, and a mist rose to the height of about four feet: then a projection descended from the black cloud which was impending, and met the ascending mist about twenty feet above the sea; the last ten yards of the distance were described with a very great rapidity. A cloud of a light color appeared to ascend in this spout like quicksilver in a glass tube. The first spout then snapped at about one-third of its height, the inferior part subsiding gradually, and the superior curling upwards.

Several other projections from the cloud appeared, with corresponding agitations of the water below, but not always in spouts vertically under them: seven spouts in all were formed; two other projections were re-absorbed. Some of the spouts were not only oblique but curved: the ascending cloud moved most rapidly in those which were vertical; they lasted from three to five minutes, and their dissipation was attended by no fall of rain. For some days before, the weather had been very rainy with a south-easterly wind; but no rain had fallen on the day of observation.

The mimic or false prester, with little or no water, is a curious vagary of nature. On the 15th of August, 1617, there was observed by the Rev. Abraham De la Pryme, F. R. S., about two o'clock in the afternoon, a water-spout in the air, at Hatfield, in Yorkshire. 'It was about a mile off, coming directly to the place where I was,' says this gentleman, 'upon which I took my perspective glasses, and made the best observations on it I could.

'The season was very dry, the weather extremely hot, the air very cloudy, and the wind pretty strong, and what was remarkable blowing out of several quarters at the same time, and filling the air with thick and black clouds, in layers; this blowing of the wind soon created a great vortex, gyration, and whirling among the clouds, the centre of which now and then dropt down in the shape of a thick long black tube, commonly called a spout; in which I could distinctly see a motion, like that of a screw, continually drawing upwards, and screwing up as it were whatever it touched. In its progress it moved slowly over a hedge row and grove of young trees, which it made bend like hazel wands, in a circular motion; then, advancing forward to a large barn, in a moment it plucked off all the thatch, and filled the whole air with it. Coming to a very large oak tree, it made it bend like the former, and broke off one of its strongest branches, and, twisting it about, flung it to a very considerable distance off. Then coming near the place where I stood, within 300 yards of me, I beheld with great satisfaction this extraordinary phenomenon, and found that it proceeded from a gyration of the clouds, by contrary winds meeting in a point or centre; and, where the greatest condensation and gravitation was, falling down into a large pipe or tube, somewhat like the cochlea Archimedis; and which, in its working or whirling motion, either sucks up water, or destroys ships, &c. Having proceeded about a quarter of a mile farther, it was dissolved by the prevalency of the wind from the east.' *Philosophical Transactions* 1702.

May the 5th, 1752, a similar phenomenon appeared about seven in the evening, in Deeping-Fen, which, from its effects, seemed to be a water-spout, broken from the clouds. A watery substance, as it seemed, was seen moving on the surface of the earth and water, in Deeping-Fen. It passed along with such violence and rapidity, that it carried every thing before it, such as grass, straw, and stubble; and, in going over the coun

try bank, it raised the dust to a great height; and when it arrived in the Wash, in the midst of the water, and just over against where Mr. R. lived, it stood still for some minutes. This watery substance spouted out water from its own surface to a considerable height, and with a terrible noise. On its second route it proceeded in a side line into a river, breaking in its passage a fishing net, and there moved along, till it came to the church, where it again stood a little while, and then made its next passage through the space between the church and the parsonage-house, towards Weston Hills and Moulton Chapel. In its way to these places it tore up a field of turnips, broke a gate off its hinges, and another into pieces. Those who saw it evaporate, affirm it ascended into the clouds in a long spearing vapor, and at last ended in a fiery stream. There was a mist like smoke frequently round it. Three more were seen at the same time in different places.—*Id.* 1751.

We subjoin the following as the most modern and amongst the most able accounts of the water-spout from Dr. Brewster's Journal. It is part of a letter from captain Napier, R. N., to that gentleman, dated 17th July 1821. 'I take the liberty of offering you the following observations, with the remarks made at the time, when the facts and appearances exhibited by this extraordinary phenomenon were deeply impressed upon my mind. On the 6th of September 1814, in lat. 30° 47′ N., and long. per chronometer 62° 40′ W., at 1*h*. 30*m*. P. M., the wind being variable between W. N. W. and N. N. E., the ship steering south-east, an extraordinary sort of whirlwind was observed to form about three cables length from the starboard bow of H. M. S. Erne. It carried the water up along with it in a cylindrical form, in diameter to appearance like that of a water-butt, gradually rising in height, increasing in bulk, advancing in a southerly direction, and, when at the distance of a mile from the ship, it continued stationary for several minutes, boiling and foaming at the base, discharging an immense column of water, with a rushing or hissing noise, into the overhanging clouds; turning itself with a quick spiral motion, constantly bending and straightening, according as it was affected by the variable winds which now prevailed alternately from all points of the compass. It next returned to the northward in direct opposition to the then prevailing wind, and right upon the ship's starboard beam, whose course was altered to east, in hopes of letting it pass a-stern. Its approach however was so rapid, that we were obliged to resort to the usual expedient of a broadside, for the purpose of averting any danger that might be apprehended, when, after firing several shots, and one, in particular, having passed right through it at the distance of one-third from its base, it appeared for a minute as if cut horizontally in two parts, the divisions waving to and fro in different directions, as agitated by opposite winds, till they again joined for a time, and at last dissipated in an immense dark cloud or shower of rain. The near edge showered in large heavy drops on the ship's deck, until the cloud was quite exhausted.

'At the time of its being separated by the effect of the shot, or more probably by the agitation occasioned in the air by the discharge of several guns, its base was considerably within half a mile of the ship, covering a portion of the surface of the water, at least half a furlong, or even 300 feet in diameter, from one extreme circumference of ebullition to the other, and the neck of the cloud into which it discharged itself appeared to have an altitude of 40° of the quadrant, while the cloud itself extended over-head, and all round to a very considerable distance. Allowing, then, from the ship, a base of a little more than one-third of a nautical mile, say 2050 feet, and an angle of 40° to the top of the neck, we shall then have, for the perpendicular height of the spout, about 1720 feet, or very nearly one-third of a statute mile. A little before it burst, two other water-spouts, of an inferior size, were observed to the southward, but their continuance was of short duration. When danger was no longer to be apprehended, I observed the barometer, and found it at 30$\frac{1}{10}$ inches, with the surface of the mercury very convex, an appearance which it had not assumed when at the same height at noon, about two hours before; the thermometer stood at 82°, having risen 1° since that time.

'During the continuance of the water-spout, and the subsequent rain, which might be a little more than half an hour, the wind blew from all points of the compass at different times, generally shifting at opposite points, never stronger than a fresh breeze for a moment, but in most instances quite light. It was unattended with any thunder or lightning, and the water that fell from the cloud, and was caught in the foot of the driver, was perfectly fresh.

'Having witnessed this extraordinary phenomenon, I endeavored to ascertain its cause, taking for granted the following axioms:—1. 'That water in a vacuum rises only to the height of thirty-two feet,' or, in other words, 'that a column of water thirty-two feet high is equal in weight to a column of the atmosphere of the same base.' 2. 'That a column of mercury twenty-nine inches high, in vacuo, is equal to the same.' 3. 'That heat rarifies the air and causes a vacuum.' 4. 'That when, the lower atmosphere is so much rarified as to become lighter than the impending clouds, then these clouds or vapors fall and disperse on the surface of the earth in the shape of rain or moisture.' 5. 'That, when the clouds descend, the mercury in the barometer also descends, and that when the vapors rise through the lower atmospheres, becoming again more dense than the vapors themselves, the mercury in the barometer rises also.' With these data, were next noted the various phenomena, as observed to be connected with the water-spout itself.

'1. Low, heavy, black clouds were seen to the southward at noon, the barometer standing at 30$\frac{1}{10}$ inches, and the thermometer at 81°, in a constant current of cool air; the atmosphere, in general, becoming hazy, even thick in some places, close and very hot,—the wind variable and attended with occasional drops of rain. A whirlwind next taking place, drawing the water up with it, apparently in a state like vapor or steam, advancing in a southerly direction to the above-

mentioned dark impending clouds, increasing also in height and bulk, with a quick spiral motion, till it came in contact with the end of a cloud which rather drooped to meet it; then discharging great quantities of water, not in a solid bulk, but in short unconnected streams or streaks as it were, attended with a rushing or hissing noise. 2. That after some time it returned with considerable velocity to the northward, in opposition to the wind prevailing at the ship, the water at the base boiling with a white foam, part projecting outwards to a certain circumference, and part arising in thick dark vapors, which gradually arranged themselves into thin streaks, as they gained in ascent towards the clouds, till the whole was dispersed by bursting into a heavy shower. 3. That the clouds descended, or came gradually nearer to the surface of the sea, before they were perfectly saturated, previous to bursting. 4. That these clouds extended in large dark masses over a great part of the western hemisphere, and were quite thick and dark over-head. 5. That the water-spout, at the base, covered, in diameter, about half a furlong of water; and in its most slender part, about two-thirds upwards, it was to appearance about six feet in diameter; and that, in height, it might be estimated at 1700 feet: and, lastly, that during the operation of these extraordinary phenomena in the atmosphere, the mercury in the barometer did only become more convex than before, with the thermometer rising 1°.

'In proceeding to examine the subject, we shall suppose that the water rose from the sea in vacuo, or rather in a cylindrical space approximating to that of a vacuum, and that it was caused so to rise, in part, by the pressure of the atmosphere circumscribing the base of the said vacuum. Having allowed so much, we can go no further without violating the well-known law, that 'water cannot rise in vacuo' above thirty-two feet; admitting, therefore, that it was even assisted to that small height, we shall have availed ourselves of the theory, as far as truth or reason can justify. If we say that water is drawn upwards by the suction of a cloud, as proposed to be exemplified by Mr. Oliver with a quill over a glass of water, we shall then begin to establish the theory of 'suction,' perfectly irreconcileable, also, with the equally well-known fact of the gravity of the atmosphere. Besides, the force of Mr. Oliver's lungs, over a glass of water, can bear no analogy to that of a cloud overhanging the surface of the sea. It appears also strange to talk of an empty cloud, or a half exhausted cloud, for clouds are not aerial bags, as some would have them to be, but vapors overhanging the earth at different heights from it, according to the proportion of humidity or density contained in themselves, and which, when, by reason of their greater weight, they fall within the sphere of the earth's attraction, begin to discharge themselves in rain, till, being reduced in size and density, if not totally consumed, they naturally rise above the sphere of attraction, and, regaining the higher parts of the atmosphere, again attract each other, and repeat such operations to the end of time.

'Setting aside, then, the theory of suction, and the idea that the water-spout could rise in a body to the clouds, by the pressure of the circumambient atmosphere alone, we shall have the following probabilities to bring us to a more rational conclusion. 1st, That many opposite currents of wind, all pointing towards a certain centre, and coming in contact with each other with unequal forces, cause a rotatory motion or current of themselves round a central space, which, not partaking of an equal or its former pressure, naturally becomes rarified by the existing heat, to such an extent, that it speedily acquires a state in a great degree approximating to that of a vacuum. 2dly, This continued rotatory motion of the air forms that which is usually denominated a whirlwind; and the pressure of the external atmosphere at the base, forcing the water to a reasonable height up the rarified space within, it is then carried upwards by the mechanical action of the wind in light and unconnected streaks. The space at the bottom, now becoming void, is regularly replenished by the pressure from without, till the whole spout is in due time thus perfectly completed.

'The water having now arrived at the region of the clouds, it is naturally attracted, diffused and connected with and among them, increasing in density and extent, till the lower atmosphere becoming now lighter than the clouds above, these enormous masses gradually settling downwards, distend, burst and dissipate in rain. That the mercury in the barometer did not fall with the rain, but, on the contrary, became considerably more convex, was visible from observation and may be accounted for in the following manner:—That during the whole operation of the water-spout, which continued not more than thirty minutes, the commencement was too sudden, and the duration too short, to cause any change indicative of what actually took place; and that this convexity only prognosticated what would have taken place, had there been no water-spout at all, and what actually did happen afterwards, viz. a very clear atmosphere and hot sultry weather.

'Although this phenomenon was rather terrific in appearance, yet I am not inclined to think it would have been attended with any serious calamity to the ship, had even the whole quantity fallen on board, allowing the loftier sails to have been taken in, the hatches battened down, and scuppers open. The cylinder or spout, coming in contact with the masts and rigging, would naturally be destroyed; and, the air rushing in instantaneously to restore the equilibrium, the torrent would be thus checked in its fall to the mere weight or force of a tropical descent. I have heard many reports of ravages committed by these aqueous meteors, but never yet met a person who had actually witnessed or experienced any such distressing effects. Upon comparing the present account with that of Mr. Maxwell's, illustrated by a very striking representation, it appears that, when completed, the two spouts are almost perfectly alike, but originally had derived their first formation from different sources. The cause of the whirlwind must be the same in all cases.

'Mr. Maxwell distinctly states, 'that, at the first formation, the black cloud drops from a

level surface into a conical form, before the disturbance at the surface of the sea is visible. The black conical cloud continues to descend till it almost reaches the surface of the sea, and the smoke-like appearance at the surface rises higher and higher, till it forms a union with the cloud from which that spout appeared to be suspended.' In this instance, the whirlwind must have commenced, and been complete, sooner in the region of the clouds than at the surface of the sea, and thus attracted and brought down with it all those vapors that first came within its influence, meeting in its descent a portion of water, of a 'smoke-like appearance,' rising from the sea itself, contained, of course, within the vacuum there more recently completed.

'This appears just as probable as that the whirlwind and spout should have commenced first at the surface of the sea, and then risen upwards, as in the other instance; for it has been seen that this spout traversed a considerable distance to the southward, before it came in contact with a cloud, which 'rather drooped to meet it.' In both instances, however, the clouds and sea were connected by a long column of water, but the latter, having had its origin at the sea, increased to a much greater bulk, even to the formation of clouds themselves; whereas the former, having originated aloft, acted merely as a canal or duct, through which the clouds discharged themselves into the ocean below. In the case given by Mr. Maxwell the spout must have been of smaller dimensions, and a less terrific appearance than the subject of the present paper, and from the very obvious cause of its having originated aloft instead of below. In the formation of whirlwinds there can be no fixed or determinate rule, why a preference should be given to their being generated at any one particular altitude between the clouds and sea, in preference to another; and if we take it for granted that they are essential to the formation of water-spouts, or that a spout cannot exist without a previous whirlwind, it then naturally follows, that the dimensions of such a spout must, in a very great measure, depend upon the original proximity of the whirlwind to the sea itself, the sea affording a more copious supply of aqueous material, than the less substantial fabric of a cloud. The water that fell into the foot of the driver, on board the Erne, was certainly quite fresh to the taste, and it will be difficult to ascertain when and where the process of distillation was effected. In the mean time, however, it may reasonably be admitted, that the admixture of the salt-water from the sea, with the fresh-water in the clouds, the latter being in far greater proportion than the former, is of itself sufficient to account for the chemical change that had thus taken place in so short a space of time.

'Whenever we are better acquainted with the effect of coming in actual contact with one of these giants of the deep, we shall then be enabled to comply with the recommendations inserted at the end of Mr. Maxwell's paper; but as there does exist at present, in the minds of all seamen, a most indescribable aversion to any intentional familiarity with meteors of such doubtful tendency, it may be difficult to find one who shall court a closer acquaintance for the mere purpose of science, in preference to the usual employment of every individual exertion of getting out of the way as fast as possible. In case of the ship's being becalmed, and every thing secured, and when one cannot do better, as was very much the case on board the Erne, it would be well to make every possible remark and observation, but such opportunities are said to be of very rare occurrence.'

Sect. IX.—Of Meteoric Stones.

These remarkable productions of the atmosphere, usually descending after the explosion of some of its heterogeneous compounds, have excited human attention in all ages. Yet as late as the year 1769 the French Academy of Sciences asserted their falling from the atmosphere to be impossible. The Chinese have only pushed their philosophy to the opposite pole of absurdity by considering them to be connected with contemporary events. Yet the oriental has been, as it was likely to be, the less injurious error to science; for it has led that wonderful people to preserve extensive catalogues of meteoric stones.

'While all Europe,' says the celebrated Vauquelin, 'resounded with the rumor of stones fallen from the heavens; and while philosophers, distracted in opinion, were framing hypotheses to explain their origin, each according to his own fancy, the honorable Mr. Howard, an able English chemist, was pursuing in silence the only route which could lead to a solution of the problem. He collected specimens of stones which had fallen at different times, procured as much information as possible respecting them, compared the physical or exterior characters of these bodies; and even did more, in subjecting them to chemical analysis, by means as ingenious as exact. It results from his researches that the stones which fell in England, in Italy, in Germany, in the East Indies, and in other places, have all such a perfect resemblance, that it is almost impossible to distinguish them from each other; and what renders the similitude more perfect and more striking is, that they are composed of the same principles, and nearly in the some proportions.'

'I should have abstained,' continues he, 'from any public notice of an object, which has been treated of in so able a manner by the English chemist, if he himself had not induced me to do so, during his residence in Paris; had not the stones which I analysed been from another country; and had not the interest excited by the subject rendered this repetition excusable. It is therefore to gratify Mr. Howard; to give, if possible, more weight to his experiments; and to enable philosophers to place full confidence in them, rather than to offer any thing new, that I publish this memoir.' *Journal des Mines*, No. 76; and *Tilloch's Mag.* vol. xv. p. 346

'It is remarkable,' says Dr. Ure, 'that all the stones, at whatever period, or in whatever part of the world they may have fallen, have appeared, as far as they have been examined, to consist of the same substances; and to have nothing similar to them, not only among the minerals in the neighbourhood of the places

where they were found, but among all that have hitherto been discovered in our earth, as far as men have been able to penetrate. For the chemical analysis of a considerable number of specimens we are particularly indebted to Mr. Howard, as well as to Klaproth and Vauquelin; and a precise mineralogical description of them has been given by the count de Bournon and others. They are all covered with a thin crust of a deep black color, they are without gloss, and their surface is roughened with small asperities. Internally they are grayish, and of a granulated texture, more or less fine. Four different substances are interspersed among their textures, easily distinguished by a lens. The most abundant is from the size of a pin's head to that of a pea, opaque, with a little lustre like that of enamel, of a gray color, sometimes inclined to brown, and hard enough to give faint sparks with steel. Another is a martial pyrites, of a reddish-yellow color, black when powdered, not very firm in its texture, and not attractible by the magnet. A third consists of small particles of iron in a perfectly metallic state, which give to the mass the quality of being attracted by the magnet, though in some specimens they do not exceed two per cent. of the whole weight, while in others they extend to a fourth. These are connected together by a fourth of an earthy consistence in most, so that they may be broken to pieces by the fingers with more or less difficulty. The black crust is hard enough to emit sparks with steel, but may be broken by a stroke with a hammer, and appears to possess the properties of the very attractible black oxide of iron. Their specific gravity varies from 3·352 to 4·281. The crust appears to contain nickel united with iron, but Mr. Hatchett could not determine its proportion. The pyrites he estimates at iron ·68, sulphur ·13, nickel ·06, extraneous earthy matter ·13. In the metallic particles disseminated through the mass, the nickel was in the proportion of one part, or thereabout, to three of iron. The hard separate bodies gave silex ·50, magnesia ·15, oxide of iron ·34, oxide of nickel ·025; and the cement, or matrix, silex ·48, magnesia ·18, oxide of iron ·34, oxide of nickel ·025. The increase of weight in both these arose from the higher oxidation of the iron. These proportions are taken from the stones that fell at Benares on the 19th of December, 1798. M. G. Rose of Berlin has succeeded in separating crystals of pyroxene from a large specimen of the aërolite of Juvenas, and has measured the angles with the reflective goniometer; one of the crystals is of the octohedral variety, represented in the 109th figure of Haüy's Mineralogy. The same rocky tissue contains microscope hemitrope crystals, which appear to be felspar, with a base of soda, i. e. albite. In the aërolite of Pallus the olivine is perfectly crystallised. The solitary masses of native iron that have been found in Siberia, Bohemia, Senegal, and South America, likewise agree in the circumstance of being an alloy of iron and nickel; and are either of a cellular texture, or have earthy matter disseminated among the metal. Hence a similiar origin has been ascribed to them.

'Laugier, and afterwards Thenard, found chrome likewise, in the proportion of about one per cent., in different meteoric stones they examined. In all the instances in which these stones have been supposed to fall from the clouds, and of which any perfect account has been given, the appearance of a luminous meteor, exploding with loud noise, has immediately preceded, and hence has been looked to as the cause. The stones likewise have been more or less hot, when found immediately after their supposed fall. Different opinions, however, have been entertained on this subject, which is certainly involved in much difficulty. Some have supposed them to be merely projected from volcanoes; while others have suggested, that they might be thrown from the moon; or be bodies wandering through space, and at length brought within the sphere of attraction of our planet.

'Various lists of the periods, places, and appearances of these showers of stony and earthy matters, have been given from time in the scientific journals. The latest and most complete is that published in the first volume of the Ed. Phil. Journ. compiled partly from a printed list by Chladni, and partly from a manuscript one of Mr. Allan, read some years ago at the Royal Society of Edinburgh. It appears that Domenico Troili, a Jesuit, published at Modena, in 1766, a work entitled Della Caduta di un Sasso dall Aria, ragionamento, in which the ingenious author proves, in the clearest manner, both from ancient and modern history, that stones had repeatedly fallen from the heavens. This curious dissertation (ragionamento) is in the possession of Mr. Allan. The compiler of the new list justly observes, that nothing can show more strikingly the universality and obstinacy of that scepticism which discredits every thing that it cannot understand, than the circumstance that his work should have produced so little effect, and that the numerous falls of meteoric stones should have so long been ranked among the inventions of ignorant credulity. Mr. Howard's admirable dissertation was published in the Phil. Trans. for 1802. It is reprinted in the thirteenth volume of Tilloch's Magazine, and ought to be studied as a pattern of scientific research.'

The following table is from the thirty-first vol. of the Ann. de Chimie:—

Chronological List of Meteoric Stones.

Sect. I.—*Before the Christian Era.*

Division 1.—Containing those which can be referred pretty nearly to a date.

A. C.

1478. The thunderstone in Crete, mentioned by Malchus, and regarded probably as the symbol of Cybele.—*Chronicle of Paros*, l. 18, 19.

1451. The shower of stones which destroyed the enemies of Joshua at Bethoron, was probably hail.—*Joshua*, chap. x. 11.

1200. Stones preserved at Orchomenos.—*Pausanias.*

1168. A mass of iron upon Mount Ida, in Crete.—*Chronicle of Paros*, l. 22.

705 or 704. The ancyle, or sacred shield, which fell in the reign of Numa. It had nearly the same shape as those which fell at the Cape and at Agram.—*Plutarch, in Num.*

654. Stones which fell upon Mount Alba in the reign of Tullus Hostilius. 'Crebri cecidere cœlo lapides.'—*Liv.* l. 30.

644. Five stones which fell in China, in the country of Song.—*De Guignes.*

465. A large stone at Ægospotamos, which Anaxagoras supposed to come from the sun. It was as large as a cart, and of a burnt color. 'Qui lapis etiam nunc ostenditur, magnitudine vehis, colore adusto.'—*Plutarch, Pliny,* lib. ii. cap. 58.

465. A stone near Thebes.—*Scholiast of Pindar.*

211. Stones fell in China along with a falling star.—*De Guignes,* &c.

205 or 206. Fiery stones.—*Plutarch, Fab. Max.* cap. 2.

192. Stone fell in China.—*De Guignes.*

176. A stone fell in the Lake of Mars. 'Lapidem in Agro Crustumino in Lacum Martis de cœlo cecidisse.'—*Liv.* xli. 3.

90 or 89. 'Eodem causam dicente, lateribus coctis pluisse, in ejus anni acta relatum est.' —*Plin. Nat. Hist.* lib. ii. cap. 56.

89. Two large stones fell at Yong in China. The sound was heard over forty leagues.—*De Guignes.*

56 or 52. Spongy iron fell in Lucania.—*Plin.*

46. Stones fell at Acilla.—*Cæsar.*

38. Six stones fell in Leang in China.—*De Guignes.*

29. Four stones fell at Po in China.—*De Guignes.*

22. Eight stones fell from heaven, in China.—*De Guignes.*

12. A stone fell at Ton-Kouan.—*De Guignes.*

9. Two stones fell in China.—*De Guignes.*

6. Sixteen stones fell in Ning-Tcheon, and other two in the same year.—*De Guignes.*

Division 2.—Containing those of which the date cannot be determined.

The mother of the gods, which fell at Pessinus.

The stone preserved at Abydos.—*Plin.*

The stone preserved at Cassandria.—*Plin.*

The black stone, and also another preserved in the Caaba of Mecca.

The 'thunderbolt, black in appearance like a hard rock, brilliant and sparkling,' of which the blacksmith forged the sword of Antar.—See *Quarterly Review,* vol. xxi. p. 225, and *Antar,* translated by T. Hamilton, Esq., page 152.

The stone preserved in the coronation chair of the kings of England was not meteoric.

Sect. II.—*After the Christian Era.*

P. C.

In the years 2, 106, 154, 310, and 333, stones fell in China.—*Abel Remusot. Journ. de Physique,* May 1819.

A stone in the country of the Vocontini.—*Plin.*

452. Three large stones fell in Thrace.—*Cedrenus* and *Marcellini, Chronicon.* p. 29. 'Hoc tempore,' says Marcellinus, 'tres magni lapides e cœlo in Thracia ceciderunt.'

Sixth century. Stones fell upon Mount Lebanon, and near Emisa in Syria.—*Damascius.*

About 570. Stones near Bender in Arabia.—*Alkoran,* viii. 16, and cv. 3 and 4.

648. A fiery stone at Constantinople.—*Several Chronicles.*

823. A shower of pebbles in Saxony.

839. Stones fell in Japan.—*Abel Remusat.*

852. A stone fell in Tabaristan, in July or August.—*De Sacy* and *Quatremere.*

856. In December, five stones fell in Egypt.—*The same.*

885. Stones fell in Japan.—*Abel Remusat.*

897. A stone fell at Ahmedabad.—*Quatremere.* In 892, according to the *Chron. Syr.*

921. Great stones fell at Narni. *Benedictus de Saint-Andrea,* in the library of prince Chigi at Rome.

951. A stone fell near Augsburg.—*Alb. Stad.* and others.

998. Two stones fell, one near the Elbe, and the other in the town of Magdeburg.—*Cosmas* and *Spangenberg.*

1009. A mass of iron fell in Djordjan.—*Avicenna.*

1021. Stones fell in Africa between the 24th of July and the 21st of August.—*De Sacy.*

1112. Stones or iron fell near Aquileja.—*Valvasor.*

1135 or 1136. A stone fell at Oldisleben in Thuringia.—*Spangenberg,* and others.

1164. During pentecost, iron fell in Misnia. —*Fabricius.*

1249. Stones fell at Quedlinbourg, Ballenstadt, and Blackenburg, on the 26th July.—*Spangenberg* and *Rivander.*

Thirteenth century. A stone fell at Wurzburg. —*Schottus, Phys. Cur.*

Between 1251 and 1363. Stones fell at Welikoi-Ustiug in Russia.—*Gilbert's Ann.,* tom. 35.

1280. A stone fell at Alexandria in Egypt.—*De Sacy.*

1300 nearly. Great stones fell in Arragon.—*Manuscript Chronicle* in the national museum of Pest in Hungary.

1304, October 1. Stones fell at Friedland or Friedberg.—*Kranz* and *Spangenberg.*

1305. Stones fell in the country of the Vandals.

1328. January 9. In Mortahiah and Dakhaliah. —*Quatremere.*

1368. A mass of iron in the Duchy of Oldenburg.—*Siebrand, Meyer.*

1379, May 26. Stones fell at Minden in Hanover.—*Lerbecius.*

1421. A stone fell in the island of Java.—*Sir T. S. Raffles.*

1438. A shower of spongy stones at Roa, near Burgos in Spain.—*Proust.*

—— A stone fell near Lucerne.—*Cysat.*

1474. Two great stones fell near Viterbo.—*Bibliotheca Italiana,* September, 1820.

1491, March 22. A stone fell near Crema—*Simoneta.*

1492, November 7. A stone of 260 lbs. fell at Ensisheim near Sturgau, in Alsace. It is now in the library of Colmar, and has been reduced to 150 lbs.—Trithemius, *Hirsaug. Annal. Conrad Gesner, Liber. de Rerum Fossilium, Figuris,* cap. iii. p. 66. in his *Opera Zurich,* 1565

1496, January 26 or 28. Three stones fell between Cesena and Bertonori.—*Buriel* and *Sabellicus*.

1511, September 4. Several stones, some of which weighed 11 lbs. and others 8 lbs., fell at Crema.—*Giovanni del Prato*, and others.

1520, May. Stones fell in Aragon.—*Diego de Sayas*.

1540, April 28. A stone fell in the Limousin.—*Bonav. de Saint Amable?*

Between 1540 and 1550. A mass of iron fell in the forest of Naunhoff.—*Chronicle of the Mines of Misnia*.

—— Iron fell in Piedmont.—*Mercati* and *Scaliger*.

1548, November 6. A black mass fell at Mansfeld in Thuringia.—*Bonav. de Saint Amable*.

1552, May 19. Stones fell in Thuringia near Schlossingen.—*Spangenberg*.

1559. Two large stones, as large as a man's head, fell at Miscolz in Hungary, which are said to be preserved in the treasury at Vienna.—*Sthuanfi*.

1561, May 17. A stone called the arx Julia fell at Torgau and Eilenborg.—*Gesner* and *De Boot*.

1580, May 27. Stones fell near Gottingen.—*Bange*.

1581, July 26. A stone, 39 lbs. weight, fell in Thuringia. It was so hot that no person could touch it.—*Binhard, Olearius*.

1583, January 9. Stones fell at Castrovillari.—*Casto, Mercati*, and *Imperati*.

—— March 2. A stone fell in Piedmont of the size of a grenade

1591, June 19. Some large stones fell at Kunnersdorf.—*Lucas*.

1596, March 1. Stones fell at Crevalcore.—*Mittarelli*.

In the sixteenth century, not in 1603. A stone fell in the kingdom of Valencia.—*Cassius* and the *Jesuits of Coimbra*.

1618, August. A great fall of stones took place in Styria.—*Hammer*.

—— A metallic mass fell in Bohemia.—*Kronland*.

1621, April 17. A mass of iron fell about 100 miles south-east of Lahore.—*Jehan Gui 's Memoirs*.

1622, January 10. A stone fell in Devonshire.—*Rumph*.

1628, April 9. Stones fell near Hatford in Berkshire; one of them weighed 24 lbs.—*Gent. Mag*. December 1796.

1634, October 27. Stones fell in Charollois.—*Morinus*.

1635, June 21. A stone fell at Vago in Italy?

—— July 7, or September 29. A stone weighing about 11 oz. fell at Calce.—*Valisnieri*, Opere, vi. 64?

1636, March 6. A burnt-looking stone fell between Sagan and Dubrow in Silesia.—*Lucas* and *Cluverius*.

1637, November 29. Gassendi says, a stone of a black metallic color fell on Mount Vaision, between Guillaume and Perne in Provence. It weighed 54 lbs. and had the size and shape of the human head. Its specific gravity was 3·5. *Gassendi, Opera*, p. 96. Lyons 1658.

1642, August 4. A stone weighing 4 lbs. fell between Woodbridge and Aldborough in Suffolk.—*Gent. Mag*. December 1796.

1643, or 1644.—Stones fell in the sea.—*Wurfbain*.

1647, February 18. A stone fell near Zwicau.—*Schmid*.

—— August. Stones fell in the bailliage of Stolzenem in Westphalia.—*Gilbert's Annal*.

Between 1647 and 1654. A mass fell in the sea—*Willman*.

1650, August 6. A stone fell at Dordrecht.—*Senguerd*.

1654, March 30. Stones fell in the island of Funen.—*Bartholinus*.

A large stone fell at Warsaw.—*Petr. Borellus*.

A small stone fell at Milan, and killed a Franciscan.—*Museum Septalianum*.

1668, June 19 or 21. Two stones, one 300 lbs. and the other 200 lbs. weight, fell near Verona.—Legallois, *Conversations*, &c., Paris 1672. Valisnieri, *Opere*, ii. p. 64, 66. *Montanon* and *Francisco Carli*, who published a letter containing several curious notices respecting the fall of stones from the heavens.

1671, February 27. Stones fell in Suabia.—*Gilbert's Annal*. tom. xxxiii.

1674, October 6. Two large stones fell near Glaris.—*Scheuchzer*.

Between 1675 and 1677, a stone fell into a fishing-boat near Copinshaw.—*Wallace's Account of Orkney*, and *Gent. Mag*. July 1806.

1677, May 28. Several stones, which probably contained copper, fell at Ermundorf near Roosenhaven.—Misc. *Nat. Cur*. 1677. App.

1680, May 18. Stones fell at London.—*King*.

1697, January 13. Stones fell at Pentolina near Sienna.—*Soldani* after *Gabrieli*.

1698, May 19. A stone fell at Waltring.—*Scheuchzer*.

1706, June 7. A stone of 72 lbs. fell at Larissa in Macedonia. It smelt of sulphur, and was like the scum of iron.—*Paul Lucas*.

1715, April 11. Stones fell not far from Stargard in Pomerania.—*Ann. de Gilbert*, lxxi. p. 215.

1722, June 5. Stones fell near Sheflar in Freisingen.—*Meichelbeck*.

1723, June 22. About thirty-three stones, black and metallic, fell near Plescowitz in Bohemia.—*Rost* and *Stepling*.

1727, July 22. Stones fell at Liboschitz in Bohemia.—*Stepling*.

1738, August 18. Stones fell near Carpentras.—*Castillon*.

1740, October 25. Stones fell at Rasgrad.—*Gilbert's Annal*, tom. i.

—— to 1741. A large stone fell in winter in Greenland.—*Egede*.

1743. Stones fell at Liboschitz in Bohemia.—*Stepling?*

1750, October 1. A large stone fell at Niort near Coutance.—*Huard* and *Lalande*.

1751, May 26. Two masses of iron of 71 lbs. and 16 lbs. fell in the district of Agram, the capital of Croatia. The largest of these is now in Vienna.

1753, July 3. Four stones, one of which weighed 13 lbs. fell at Strkow near Tabor.—

Stepling, De Pluvia Lapidea, anno 1753, ad Strkow, et ejus causis, meditatio, p. 4.—*Prag.* 1754.

1750, September. Two stones, one of 20 lbs. and the other of 11 lbs., fell near the villages of Laponas and Pin in Berne.—*Lalande* and *Richard.*

1752, July. A stone fell in Calabria, at Terranuova, which weighed 7 lbs. 7½ oz.—*Domin. Tata.*

1766, end of July. A stone fell at Alboreto in Modena.—*Troil.*

—— August 15. A stone fell at Novellara.—*Troili*?

1768, September 13. A stone fell near Luce in Maine. It was analysed by Lavoisier, &c.—*Mem. Acad. Par.*

—— A stone fell at Aire.—*Mem Acad. Par.*

—— November 20. A stone weighing 38 lbs. fell at Mauerkirchen in Bavaria.—*Imhof.*

1773, November 17. A stone weighing 9 lbs. 1 oz. fell at Sena in Arragon.—*Proust.*

1775, September 19. Stones fell near Rodach in Cobourg.—*Gilbert's Annal.* tom. xxiii.

—— or 1776. Stones fell at Obruteza in Volhynia.—*Gilbert's Annal.* tom. xxxi.

1776 or 1777, January or February, Stones fell near Fabriano.—*Soldani* and *Amoretti.*

1779. Two stones weighing 3½ oz. each, fell at Pettiswoode in Ireland.—*Bingley, in Gent. Mag.* September 1796.

1780, April 1. Stones fell near Beeston in England.—*Evening Post.*

About 1780. Masses of iron fell in the territory of Kinsdale, between West-River Mountain and Connecticut.—*Quarterly Review*, No. 59, April, 1824.

1782. A stone fell near Turin.—*Tata* and *Amoretti.*

1785, February 19. Stones fell at Eichstadt. *Pickel* and *Stus.*

1787, October 1. Stones fell in the province of Charkow in Russia.—*Gilbert's Annal.* tom. xxxi.

1790, July 24. A great shower of stones fell at Barbotan near Roquefort, in the vicinity of Bourdeaux. A mass fifteen inches in diameter penetrated a hut, and killed a herdsman and a bullock. Some of the stones weighed 25 lbs. and others 30 lbs.—*Lomet.*

1791, May 17. Stones fell at Cassel-Beradenga, in Tuscany.—*Soldani.*

—— October 20. Stones fell at Menabilly, in Cornwallis.—*King.*

1794, June 16. Twelve stones, one of which weighed 7½ oz., fell at Sienna. Howard and Klaproth have analysed these stones.—*Philosophical Transactions*, 1794, p. 103.

1795, April 13. Stones fell at Ceylon.—*Beck.*

—— December 13. A large stone weighing 55 lbs. fell near Wold Cottage in Yorkshire. No light accompanied the fall.—*Gent. Mag.* 1796.

1796, January 4. Stones fell near Belaja-Zerkwa in Russia.—*Gilbert's Annal.* tom. xxxv.

—— February 19. A stone of 10 lbs. fell in Portugal.—*Southey's Letters from Spain.*

1798, March 8 or 12. Stones, one of which was the size of a calf's head, fell at Sales.—*Marquis de Drée.*

—— December 19. Stones fell in Bengal—*Howard, Lord Valentia.*

1801. Stones fell on the island of Tonneliers.—*Bory de St. Vincent.*

1802, September. Stones fell in Scotland?—*Monthly Magazine*, October 1802.

1803, April 26. A great fall of stones took place at Aigle. They were about 3000 in number, and the largest weighed about 17 lbs.

—— July 4. Stones fell at East Norton.—*Phil. Mag.* and *Bibl. Brit.*

—— October 8. A stone fell near Apt.

—— December 13. A stone fell near Eggenfielde in Bavaria weighing 3½ lbs.—*Imhof.*

1804, April 5. A stone fell at Possil, near Glasgow.—*Phil. Mag.*

——— 1807. A stone fell at Dordrecht.—*Van Beck Calkoen.*

1805, March 25. Stones fell at Doroninsk in Siberia.—*Gilbert's Annal.* tom. xxix. and xxxi.

—— June. Stones covered with a black crust fell in Constantinople.—*Kengas Ingigian.*

1806, March 15. Two stones fell at St. Etienne and Valence; one of them weighed 8 lbs.

—— May 17. A stone weighing 2½ lbs. fell near Basingstoke in Hampshire.—*Monthly Magazine.*

1807, March 13 (June 17 according to Lucas). A stone of 160 lbs. fell at Timochin, in the province of Smolensko in Russia.—*Gilbert's Annal.*

—— December 14. A great shower of stones fell near Weston in Connecticut. Masses of 20 lbs. 25 lbs. and 35 lbs. were found.—*Silliman and Kingsley.*

1808, April 19. Stones fell at Borgo San Donino.—*Guidotti* and *Sgagnoni.*

—— May 22. Stones weighing 4 lbs. or 5 lbs. fell near Stannern in Moravia.—*Bibl. Brit.*

—— September 3. Stones fell at Lissa in Bohemia.—*De Schreibers.*

1809, June 17. A stone of 6 oz. fell on board an American vessel, in lat. 30° 58′ N., and long. 70° 25′ W.—*Bibl. Brit.*?

1810, January 30. Stones, some of which weighed about 2 lbs, fell in Caswell county, North America.—*Phil. Mag.* vol. xxxvi.

—— July. A great stone fell at Shahabad in India. It burned five villages, and killed several men and women.—*Phil. Mag.* xxxvii. p. 236.

—— August 10. A stone weighing 7¾ lbs. fell in the county of Tipperary in Ireland.—*Phil. Mag.* vol. xxxviii. Mr. W. Higgins published an analysis of it.

—— November 23. Stones fell at Mortelle, Villerai, and Moulinbrulé, in the department of the Loiret; one of them weighed 40 lbs. and the other 20 lbs.—*Nich. Journal*, vol. xxxix. p. 158.

1811, March 12 or 13. A stone of 15 lbs. fell in the province of Poltawa in Russia.—*Gilbert's Annals*, xxxviii.

—— July 8. Stones, one of which weighed 3½ oz., fell near Berlanguillas in Spain.—*Bibl. Brit.* tom. xlviii. p. 162.

1812, April 10. A shower of stones fell near Thoulouse.

—— April 15. A stone, the size of a child's head, fell at Erxleben. A specimen of it is in the possession of Professor Haussman of Brunswick. *Gilbert's Annal.* xl. and xli.

—— August 5. Stones fell at Chantonay.—*Brochant.*

1813, March 14. Stones fell at Cutro in Calabria, during a great fall of red dust.—*Bibl. Brit.* October 1813.

—— September 10. Several stones, one of which weighed 17 lbs., fell at Limerick in Ireland.—*Phil. Mag.*

1814, February 3. A stone fell at Bacharut in Russia.—*Gilbert's Annal.* tom. i.

—— September 5. Stones, some of which weighed 8 lbs., fell in the vicinity of Agen.—*Phil. Mag.* vol. xlv.

—— November 5. Stones, of which nineteen were found, fell in the Doab in India.—*Phil. Mag.*

1815, February 18. A stone fell at Duralla in India.—*Phil. Mag. Journal of Science.*

—— October 3. A large stone fell at Chassigny, near Langres.—*Pistollet. Ann. de Chim.*

1816. A stone fell at Glastonbury in Somersetshire.—*Phil. Mag.*

1817, May 2 and 3. There is reason to think that masses of stone fell in the Baltic after the great meteor of Gottenburg.—*Chladni?*

1818, February 15. A great stone appears to have fallen at Limoge, but it has not been disinterred.—*Gazette de France*, Feb. 25, 1818.

—— March 30. A stone fell near Zuborzyca in Volhynia (analysed by *M. Laugier, Ann. de Museum*, 17th year, 2d number).

—— July 29. O. S. A stone of 7 lbs. fell at the village of Slobodka in Smolensko. It penetrated nearly sixteen inches into the ground. It had a brown crust with metallic spots.

1819, June 13. Stones fell at Jonzac, department of the lower Charente. These stones contain no nickel.

—— October 13. Stones fell near Politz, not far from Gera or Kostritz, in the principality of Reuss.—*Gilbert's Annals*, lxiii.

1820, 21st to 22d March. A stone fell in the night at Vedenburg in Hungary.—*Hesperus*, xxvii. *cah.* 3.

—— July 12. A stone fell near Likna, in the circle of Dunaborg, province of Witepsk in Russia.—*Th. Grotthus. Ann. de Gilbert*, lxviii.

1821, June 15. Stones fell near Juvenas, containing no nickel.

1822, June 3. A stone fell at Angers.—*Ann. de Chim.*

—— September 10. A stone fell near Carlstadt in Sweden.

—— September 13. A stone fell near La Baffe, canton of Epinal, department of Vosges.—*Ann. de Chim.*

1823, August 7. A stone fell near Nobleboro in America.—*Silliman's American Journal*, vii.

1824, towards the end of January. Many stones fell near Arenazzo, in the territory of Bologna. One of them, weighing 12 lbs., is preserved in the Observatory of Bologna.—*Diario di Roma.*

—— beginning of February. A great stone fell in the province of Irkutsk in Siberia.—*Some journals.*

—— October 14. A stone fell near Zebrak, circle of Beraum, in Bohemia. The stone is preserved in the national museum of Prague.

List of Masses of Iron supposed to have fallen from the Heavens.

Sect. I.—*Spongy or Cellular Masses containing Nickel.*

1. The mass found by Pallas in Siberia, to which the Tartars ascribe a meteoric origin. —*Voyages de Pallas*, tom. iv. p. 545. *Paris*, 1793.
2. A fragment found between Eibenstock and Johanngeorgenstadt.
3. A fragment probably from Norway, and in the imperial cabinet of Vienna.
4. A small mass weighing some pounds, and now at Gotha.
5. Two masses in Greenland, out of which the knives of the Esquimaux were made.—See Ross's *Account of an Expedition to the Arctic Regions.*

Sect. II.—*Solid Masses where the Iron exists in Rhomboids or Octohedrons, composed of Strata, and containing Nickel.*

1. The only fall of iron of this kind is that which took place at Agram in 1751.
2. A mass of the same kind has been found on the right bank of the Senegal.—*Compagnon, Forster, Goldberry.*
3. At the Cape of Good Hope; Stromeyer has lately detected cobalt in this mass.—*Van Marum* and *Dankelman; Brande's Journal*, vol. vi. 162.
4. In different parts of Mexico.—*Sonneschmidt, Humboldt*, and the *Gazette de Mexico*, tom. i. and v.
5. In the province of Bahia in Brasil. It is seven feet long, four feet wide, and two feet thick, and its weight about 14,000 lbs.—*Mornay* and *Wollaston; Phil. Trans.* 1816, p. 270, 281.
6. In the jurisdiction of San Jago del Estera.—*Rubin de Cælis*, in the *Phil. Trans.* 1788, vol. lxxviii. p. 37.
7. At Elbogen in Bohemia.—*Gilbert's Annal.* xlii. and xliv.
8. Near Lenarto in Hungary.—*Ditto*, xlix.

The origin of the following masses seems to be uncertain, as they do not contain nickel, and have a different texture from the preceding :—

1. A mass found near the Red River, and sent from New Orleans to New York.—*Journ. des Mines*, 1812, *Bruce's Journ.*
2. A mass at Aix-la-Chapelle containing arsenic. —*Gilbert's Annal.* xlviii.
3. A mass found on the hill of Brianza in the Milanese.—*Chladni* in *Gilbert's Annal.* l. p. 275.

We must not omit to add, that Dr. Brewster has furnished a very beautiful theory of the formation of meteoric stones.

METHEG'LIN, *n. s.* Welsh *meddyglin.* A word like the first syllable is found in both the eastern and northern languages for a sweet drink, see MEAD: the termination *glyn,* as Minsheu says, signifies glutinosum, glutinous. A species of fermented honey-drink.

White-handed mistress, one sweet word with thee.
—Honey and milk, and sugar; there is three.
Nay then two treys; and, if you grow so nice,
Metheglin, wort, and malmsey. *Shakspeare.*

To' allay the strength and hardness of the wine,
And with old Bacchus new *metheglin* join. *Dryden.*

METHEGLIN is a species of mead; one of the most pleasant and general drinks the northern parts of Europe afford, and much used among the ancient inhabitants. There are various methods of making it; one of the best is the following:—Put as much new honey, naturally running from the comb, into spring water as that when the honey is thoroughly dissolved an egg will not sink to the bottom, but be just suspended in it; boil this liquor for an hour or more, till the egg swim well above the liquor; when very cool, next morning, it may be barrelled up, adding to each fifteen gallons an ounce of ginger, as much of mace and cloves, and half as much cinnamon, all grossly pounded; a spoonful of yeast may also be added at the bung-hole to promote the fermentation. When it has done working it may be closely stopped up; and after it has stood a month it should be drawn off into bottles.

METHINKS', *imp. v.* } Me and thinks. A
METH'OUGHT, *pret.* } Norman corruption, confounding me and I, as Dr. Johnson observes; meseems, as he suggests, would be more grammatical: it appears to me; I think.

In all ages poets have been had in special reputation, and, *methinks,* not without great cause; for, besides their sweet inventions, and most witty lays, they have always used to set forth the praises of the good and virtuous. *Spenser on Ireland.*

Methought a serpent eat my heart away,
And you sat smiling at his cruel prey. *Shakspeare.*

Methought I saw him placable, and mild,
Bending his ear: persuasion in me grew
That I was heard with favour; peace returned
Home to my breast; and to my memory
His promise, 'That thy seed shall bruise our foe.' *Milton.*

If he choose out some expression which does not vitiate the sense, I suppose he may stretch his chain to such a latitude; but by innovation of thoughts, *methinks,* he breaks it. *Dryden.*

Methought I stood on a wide river's bank,
Which I must needs o'erpass, but knew not how. *Id.*

There is another circumstance, which, *methinks,* gives us a very high idea of the nature of the soul, in regard to what passes in dreams, that innumerable multitude and variety of ideas which then arise in her. *Addison's Spectator.*

Methinks already I your tears survey. *Pope.*

Far happier are the dead, *methinks,* than they
Who look for death and fear it every day. *Cowper.*

METH'OD, *n. s.*
METHOD'ICAL, *adj.*
METHOD'ICALLY, *adv.*
METH'ODISE,
METH'ODIST, *n. s.*
} Fr. *methode;* Lat. *methodus;* Gr. μεθοδὸς, a path or way. Order; arrangement; way; or manner: methodical is, orderly; well arranged: to methodise, to dispose in due order; to regulate: a methodist, hardly known in our language in the general sense, means particularly an ancient sect of physicians, and the large and respectable body of Christians described at length in the following article.

To see wherein the harm which they feel consisteth, the seeds from which it sprang, and the *method* of curing it, belongeth to a skill, the study whereof is full of toil, and the practice beset with difficulties. *Hooker.*

If you will jest with me know my aspect,
And fashion your demeanour to my looks,
Or I will beat this *method* in your sconce. *Shakspeare.*

To begin *methodically,* I should enjoin you travel; for absence doth remove the cause, removing the object. *Suckling.*

Our wariest physicians, not only chemists but *methodists,* give it inwardly in several constitutions and distempers. *Boyle.*

All the rules of painting are *methodically,* concisely, and clearly, delivered in this treatise. *Dryden.*

Resolved his unripe vengeance to defer,
The royal spy retired again unseen,
To brood in secret on his gathered spleen,
And *methodise* revenge. *Id. Boccace.*

It will be in vain to talk to you concerning the *method* I think best to be observed in schools, *Locke on Education.*

Notwithstanding a faculty be born with us, there are several *methods* for cultivating and improving it, and without which it will be very uncertain. *Addison's Spectator.*

The man who does not know how to *methodise* his thoughts has always a barren superfluity of words; the fruit is lost amidst the exuberance of leaves. *Id.*

He can take a body to pieces, and dispose of them where he pleases; to us, perhaps, not without the appearance of irretrievable confusion; but, with respect to his own knowledge, into the most regular and *methodical* repositories. *Rogers.*

Those rules of old discovered, not devised,
Are nature still, but nature *methodised.* *Pope.*

Method, taken in the largest sense, implies the placing of several things, or performing several operations, in such an order as is most convenient to attain some end. *Watts.*

O! what a fund of genius, pent
In narrow space, is here!
This volume's *method* and intent,
How luminous and clear. *Cowper.*

'The Trial of the Spirits,'—would make an admirable tract on the subject. But the inconvenience is that the *Methodists* would say your Lordship had written against them; an honour which, for their own sakes, one would not wish them. *Hurd's Letters to Warburton.*

METHODISTS, METHODICI, in the history of medicine, a sect of ancient physicians, who reduced the whole art of healing to a few common principles or appearances. The Methodists were the followers of Thessalus; whence they were also called Thessalici. They were strenuously opposed by Galen in several of his writings; who scrupled not to assert that the Methodical heresy ruined every thing that was good in the art. Quincy erroneously uses Methodists (Methodici) for those physicians who adhered to the doctrine of Galen and the schools, in opposition

to empirics and chemists, who used violent medicines and pretended secrets or nostrums.

METHODISTS, in ecclesiastical history, a denomination applied to different sects, both of Papists and Protestants.

METHODISTS, POPISH, were those polemical doctors of whom the most eminent arose in France, towards the middle of the seventeenth century, in opposition to the Huguenots or Protestants. These Methodists, from their different manner of treating the controversy with their opponents, may be divided into two classes. The one comprehends those doctors whose method of disputing with the Protestants was disingenuous and unreasonable, and who followed the examples of those military chiefs who shut up their troops in intrenchments and strong holds, in order to cover them from the attacks of the enemy. Of this number were the Jesuit Veron, who required the Protestants to prove the tenets of their church by plain passages of Scripture, without being allowed the liberty of illustrating those passages, reasoning upon them, or drawing any conclusions from them; Nihusius, formerly a Protestant; the two Walenburghs, and others, who confined themselves to the business of answering objections and repelling attacks; and cardinal Richelieu, who confined the whole controversy to the single article of the divine institution and authority of the church. The Methodists of the second class were of opinion that the most expedient manner of reducing the Protestants to silence was, not to attack them by piecemeal, but to overwhelm them at once by the weight of some general principle or presumption, some universal argument, which comprehended or might be applied to all the points contested between the two churches; thus imitating the conduct of those military leaders who, instead of spending their time and strength in sieges and skirmishes, endeavoured to put an end to the war by a general and decisive action. These polemics rested the defence of Popery upon prescription, the wicked lives of Protestant princes who had left the church of Rome, the crime of religious schism, the variety of opinions among Protestants with regard to doctrine and discipline, and the uniformity of the tenets and worship of the church of Rome. To this class belong Nicolle the Jansenist doctor, the famous Bossuet, &c.

METHODISTS.

METHODISTS. The rise and spread of the modern Methodists, viewed in connexion with the character of their founder and his principal associates, and the circumstances of their commencement and extension, present numerous subjects for interesting contemplation to the statesman, the philosopher, and the divine. On the peculiarities of Methodism the most opposite opinions have been formed, and these varying opinions have been expressed in almost all the forms and degrees of panegyric and vituperation. If, however, there be taken into account the widely extending influence of Methodism in both hemispheres, its strenuous and incessant activity, and the efficacy of its strong and plastic organisation, it will appear reasonable that persons should qualify themselves to form a correct opinion on the subject by calm, candid, and extended enquiry. Doubtless there must be something remarkable in a system which has been characterised in the strongest terms of admiration or censure by so many eminent observers, including persons possessing all grades of talent and opinion, between the extremes of bishops Lavington and Warburton on the one hand and Dr. Priestley on the other, and downwards again from the philosophising apostle of Unitarianism to the poetical biographer of Mr. Wesley—Dr. Southey. That which has extorted reluctant praise from many distinguished writers, who commenced their researches with no prepossessions in its favor, cannot be credibly represented as totally worthless and mischievous; and, on the other hand, while the violence with which it has been assailed and stigmatised may justly excite grave doubts respecting the competent information and candor of the impugners, their numbers and their confidence place the methodist system in a defensive position, as being under some presumptions of blame.

To develope this subject as copiously as the variety and importance of its topics deserve is incompatible with the brevity imposed by the nature of our work. Our aim therefore, in this article, will be not so much to express or enforce any opinions of our own as to furnish our readers with the means of forming their own judgment on the general character and influence of Methodism, in connexion with the chief particulars of its history.

As a term of modern use the name of Methodists appears to have been first brought forward in the days of Puritanism; being suggested by the Latin appellative, Methodistæ, which was given to a college of physicians in ancient Rome, in consequence of the strict regimen under which they placed their patients, it was of ready application to the puritans or precisians in religion, as they were then sometimes called, which is indeed a term of much the same import with that of Methodists. Appellations of this description, which convey the idea of dislike and reproach, are not likely to be soon forgotten, and stand always ready for revival under similar circumstances to those which gave them birth. When it came to pass therefore, about the year 1730, that Mr. John Wesley, then fellow of Lincoln College Oxford, had prevailed upon other members of the University, principally his own pupils, to join with himself in stricter religious observances than were at that period fashionable in Oxford, adversaries and satirists of these proceedings soon appeared, who were not slack in reviving the puritan appellation, and fixing it upon Mr. Wesley and his companions. A few years after this Messrs. John and Charles Wes-

ley and Mr. Whitefield commenced their novel career in the religious world. Partly because they were excluded from the churches for the supposed singularity and enthusiasm of their opinions, and partly because they were carried forward by the zealous feelings which those opinions did actually inspire, they began to preach in the open air, and to organise distinct religious societies. Such proceedings would of course excite public attention; and it was perfectly natural that their former college contemporaries, hearing of these things, should revive their old satirical appellative, and give it general currency and circulation.

It was also to be expected, as was actually the case, that this name should at first embrace all persons who, with whatever varying views and principles, exhibited more than ordinary concern on the subject of religion; and this comprehensive meaning is indeed, as yet, far from being exploded. Viewing it more strictly, however, as a distinct denomination of professing Christians, it includes the two great branches of Calvinistic, and Arminian or Wesleyan Methodists. The former, it is true, are to a considerable extent identified with the regular Independent dissenters. From these, however, the Calvinistic Methodists may be distinguished by some strongly marked features of difference.

1. As a body they adhere to the system of Calvinist doctrine in all its technical accuracy of statement, with less of modern and mitigating explanation than is customary among Independents in general.

2. They have chapels in London, Bristol, and other places, which owe their erection to the pious liberality of Selina, countess of Huntingdon, and the influence of Mr. Whitefield; and the appointment of ministers in these chapels is vested in trustees nominated under the regulations of the above named excellent persons, and not in members of the religious societies assembling in those chapels, according to the fundamental principles of Independency. The Calvinistic Methodists also vary from this model in another respect, being understood to be united under a federative constitution, though much looser in its provisions than that of Wesleyan Methodism.

3. The church of England in its general institutions, and especially in its liturgical services, is much more favorably considered by both the great branches of the Methodists than by the regular dissenters. Hence it frequently occurs that the forms of the church are employed amongst the Methodists in their public worship.

The specific ground, indeed, of what may perhaps be more properly called variation from the order of the establishment than formal dissent from it, amongst Methodists of all descriptions, is the desire of possessing greater advantages for the enjoyment of what they conceive to be spiritual religion than can be realised by a course of strict conformity. Their objections to the church of England incline to the side of administration, rather than of constitution; thus great numbers of Methodists resident in the country villages attend more or less punctually upon the services of the church, and bring up their families within its pale.

The way is now cleared for treating particularly of the Wesleyan Methodists, who constitute perhaps the greatest portion of the whole body of Methodists, who embrace the doctrines promulgated by the Rev. John Wesley and conduct their ecclesiastical affairs on the plan of organisation which he was led step by step to adopt, during a long course of successive years.

The various parts of this remarkable organisation Mr. Wesley was led to adopt, as occurring circumstances called for them, and a strong conviction of duty, overpowering his attachment to established order, seemed imperatively to require. From the doctrines of the church of England, as Dr. Southey well observes, he never knowingly or willingly departed, being conscientiously satisfied with them after free and full enquiry. In the interpretation of these doctrines, Mr. Wesley adopts the principles of Arminius, stated, however, in a remarkably guarded and moderate way. The doctrinal works which form the legally established standard of the body, are the first four volumes of his sermons and his notes on the New Testament. On the subject of the Trinity, and all the points of doctrine it involves, the sentiments of the Wesleyan Methodists coincide in terms with the first four general councils and the creeds and articles of the church derived from them. The doctrine likewise of the total depravity of human nature is generally held by Mr. Wesley's followers as expressed in the ninth article. Here, however, their Arminianism induces a particular explanation, if it be not a radically different modification of opinion. While with the article they hold that original sin is that corruption of nature whereby man is 'very far gone from original righteousness, and is of his own nature inclined to evil;' yet they conceive that although man, in the abstract, so to speak, is thus totally corrupt, yet considering him in the concrete, or in the reality of his actual existence, each individual of our fallen race, through the redemption which is in Christ Jesus, partakes of an ameliorating principle—a ray of vivifying light which shines in the darkness of the natural mind, and is designed to lead him fully from a death in sin to a life of righteousness. On the subject of justification, or the mode of constituting sinful man righteous before God, the only difference of any moment between the Wesleyan Methodists and orthodox Christians in general is this, that they connect with the personal justification of a sinner a certain impression on his mind which they term the witness of the Spirit. This they describe as a direct testimony, borne by the Spirit of God, to the conscience of a penitent believer, that his sins are forgiven and himself now received into the favor of God. While, however, they strenuously assert that the witness of the Spirit thus understood is the common privilege of Christians, without which they ought not to rest satisfied, yet they are far from making it the absolute sine quâ non of a gracious state. And, lest any person should be disposed to rest in the professed experience of this blessing, as superseding the necessity of a moral character formed on the precepts of the gospel, Mr. Wesley endeavours to provide a suitable guard of his doctrine in

the following terms:—'Let none ever presume to rest in any supposed testimony of the Spirit, which is separate from the fruit of it. If the Spirit of God does really testify that we are children of God, the immediate consequence will be the fruit of the Spirit, even love, joy, peace, long-suffering, gentleness, goodness, fidelity, meekness, temperance.' On the great subject of regeneration, also, it would not appear that there is any absolute irreconcilableness between Mr. Wesley's principles and those of other Christian professors. The necessity of a divine influence to create in fallen man a clean heart, and renew a right spirit within him, is common ground; and when the Methodist doctrine of the consummation of this regenerating change by a state which, in the theological nomenclature of the body, is called Christian perfection, is closely and candidly analysed, it may appear more in unison, especially with the views of the Established Church, than is commonly supposed. 'Christian perfection,' says Mr. Wesley, in his later and more matured writings on this subject, 'is a constant communion with God, which fills the heart with humble love. The only perfection of which man is capable, while he dwells in a corruptible body, is the complying with that kind command, My son, give me thine heart. It is the loving the Lord his God with all his heart, and with all his soul, and with all his mind.' On no other doctrines than these now brought forward does there appear to exist among the Methodists any material variation of statement from that usually adopted by what are called orthodox Christians. And it is proper to observe that the general scheme of Wesleyan Methodist doctrine, while substantially Arminian, is, after Mr. Wesley's example, carefully guarded from the extremes of that system, in the theological teaching of the preachers at large. The following expression of their views, as recorded in the Minutes of Conference for 1821, is worthy of particular notice:—'We again solemnly resolve, after the example of our venerable father in the Gospel, to preach a free, present, and full, salvation from sin; a salvation flowing from the mere grace of God, through the redemption which is in Christ Jesus, apprehended by the simple exercise of faith, and indispensably preparatory to a course of practical holiness. And in this great work, our only reliance for success is upon the promised grace of the Spirit, by whose inspiration alone it is, that the Gospel, in any instance, is rendered the power of God unto salvation.'

The progressive steps by which the Wesleyan Methodists became a distinct religious body may be readily anticipated by careful and intelligent observers of human character and history. The societies collected in London, Bristol, and other parts of the island, under the ministry of the Rev. J. and C. Wesley, and other clerical co-adjutors, were divided into little companies of from ten to twenty persons, called *classes*, and given in charge to a discreet person, called a leader. It was his business to preside in a weekly meeting of his class for spiritual conversation and prayer, to receive such contributions as his members were disposed to give to the relief of the poor, and the current expenses of the society, and to pay such monies over weekly to the stewards of the society, who were persons appointed to manage its temporal affairs. Soon after the formation of the society it became needful to build large rooms for general meetings of the whole society, who, thus congregated, were called *body bands*, and also for public worship; and thus it became needful to appoint suitable persons to conduct public service in these rooms by prayer and reading of sermons, or exposition of the Scriptures. These functionaries, as might be expected, soon became regular preachers; and being recognised, although at first with considerable reluctance, by Mr. Wesley, in this new character, they were appointed by him to extend their labors to the villages and hamlets of the circumjacent country. In this manner, then, originated those important territorial divisions, in the economy of Wesleyan Methodism, which are denominated *circuits*. These consist of the societies and congregations in a given tract of country surrounding some considerable place, called the head of the circuit, and where the residence of the preachers is ordinarily fixed. The circuits thus constituted are placed under the direction of one, two, or more, preachers, rarely exceeding five, according to their magnitude and importance, one of whom, generally the preacher of longest standing in the body, is entrusted with the general direction of the affairs of his circuit. His name of office was formerly the assistant, but now he is called the superintendant. The former of these names is important, as connected with the government of the Methodist body, during the life of Mr. Wesley, under whose personal administration it was actually placed. This system of government he carried on in a constant round of itinerancy, which brought him, at regular periods, through all those parts of the British islands in which Methodist societies were established. Thus he exercised a personal supervision over the whole connexion, as the great body united under himself was very appropriately designated. But, in Mr. Wesley's absence, the preacher selected by himself, and on that ground called the assistant, governed the societies in his circuit: it being understood, however, that, on all points of the exercise of his delegated authority, an appeal lay to Mr. Wesley in the *conference*. This body occupies a very important position in the Methodist connexion, and it will be needful briefly to trace the steps by which it has attained to it. The first conference, formally so called, was held in the year 1744, and was, in fact, nothing more than a company of persons choosing to carry on, in a methodical form, by way of question and answer, a discussion on Christian doctrines and principles, involving some leading peculiarities of Methodism. The persons meeting with Mr. Wesley at this first conference were clergymen. But it soon came to pass that the lay preachers, as they then were called, with the addition of two or three clergymen closely associated with Mr. Wesley, composed the conference; that the entire government and discipline of the Methodist body were treated of in that assembly; and that the discussion of these subjects constituted its regular functions. At these

annual assemblies, therefore, explanations of doctrine were brought forward, the stations of the preachers for the ensuing year were fixed, and the general and widely extending business of the body was transacted. During the life of Mr. Wesley he summoned to the conference such preachers as he pleased; and, while he heard their opinions on all the affairs which might be brought forward, he strictly reserved the ultimate decision to himself. It could not, however, fail to happen, and was, indeed, quite in conformity with Mr. Wesley's intentions, that the conference should by degrees acquire the respect and authority attaching to the ruling body in the Methodist connexion; and that the preachers in that assembly who had taken pains to acquaint themselves with the economy of the connexion, and were most largely endowed with the requisite qualities for managing public deliberations, should acquire a commanding influence over its decisions. This would increasingly be the case, in proportion as Mr. Wesley began to feel the infirmities attendant upon advancing years. His views, with regard to the conference which he had trained up for the management of the connexion, and the full exercise, after his decease, of his own authority, are fully developed in the deed of declaration, executed in 1784. The great object of this instrument was to specify the meaning of the term conference, so that there might be no uncertainty respecting the individuals who might legally officiate in various chapels, or meeting-houses, conveyed to trustees for the purpose of permitting such persons as should be appointed by 'the conference of the people called Methodists' to preach and expound the word of God therein. In this constituent act of the connexion Mr. Wesley also selects 100 of his preachers to constitute the legal conference, points out the method by which that number is to be perpetually kept up, and fixes an itinerancy or continual change of preachers as the unalterable rule of the body. A few years afterwards he departed this life, leaving a letter directed to the preachers who should assemble together in the first conference after his decease, in which he strictly charges the 100 preachers constituting the legal conference to assume on that ground no superiority over their brethren, who, having completed their probationary term of four years, were received as full members of the conference: such reception is technically called 'being admitted into full connexion.' In consequence of this solemn charge from their venerable founder the 100 have reserved to themselves no substantial superiority over their junior brethren, save what is due to age and experience. Of course, the appointment of president and secretary of the conference would properly rest in their own number; in this business, however, they adopt, as co-electors with themselves, all the preachers of fourteen years standing; in whose favor, also, is the provision that one-third of all the vacancies in the 100 shall be filled up by election from amongst them, and which, therefore, deviates thus much from the rule of seniority. In all other points the young men newly received into full connexion have an equal voice with the seniors.

In the years immediately succeeding the death of Mr. Wesley serious agitations arose in the Methodist body, which especially respected, in their first development, its peculiarity of position relative to the church of England. As, on the one hand, it is to be believed that Mr. Wesley was quite sincere in all his professions of attachment to that church; so, on the other, it cannot be successfully denied that the measures he took, towards the close of his life, went to organise and perpetuate another religious society, having in it all the institutions proper to a church of Christ, and differing materially from the Anglican church in ecclesiastical regimen. Such was the deed of declaration, the tendency of which was to legalise and perpetuate Methodism as a distinct religious system, and the ordination to the full ministry of some of the preachers, first in the newly separated states of America, then in Scotland, and finally in England itself. That Mr. Wesley contemplated also the introduction of service amongst his people, in what are called canonical hours, is probable from his abridgment of the Liturgy for their use. For the services contained in this admirable formulary, and indeed the ordinances generally of the establishment, he manifested to the end of his life the highest veneration and attachment. The following hypothesis seems best to reconcile all the facts of the case:—Mr. Wesley's views, in relation to the system of which he was the founder, varied considerably as the system itself was brought into operation upon the great mass of the people; he saw more and more clearly the obstacles which the deeply-rooted feelings of the clergy on the one hand, and of his own people on the other, interposed to the accomplishment of his ardent wishes respecting a close unison with the established church: he therefore reluctantly, but conscientiously, acquiesced in what he was constrained to believe was the will of God; this was that the Methodists should ultimately assume the character of a distinct religious society, fully provided in itself with all things necessary to the structure of a Christian church, and yet subsisting in a form as little opposed to the church of England as was compatible with such an organisation. To this effect when, in A.D. 1788, Mr. Wesley set apart Messrs. A. Mather, Thomas Rankin, and Henry Moore, for the sacred office by imposition of hands and prayer, without sending them out of England; he strongly advised them, that, according to his example, they should continue united to the established church, so far as the blessed work in which they were engaged would permit.—*Myles's Chronological History*.

Such was the posture of things in external and internal relations in which the Methodist connexion found itself at Mr. Wesley's death. On this event the conference entered into that full authority over the whole body, which Mr. Wesley designed should in that case devolve upon them. In order, therefore, to provide fully for the continuance of this ever active and ready supervision of the body, in the exercise of every part of its discipline so far as might be needful during the intervals of its annual sessions, they divided the connexion into *districts*, composed of all the itinerant preachers stated in a given number of

circuits; and by subsequent provisions, so far as financial matters are concerned, the stewards of the circuits are, in district meetings, associated with them. These are officers to whom is entrusted the management of the temporal affairs of the circuits. These districts, now placed under the superintendance of a chairman, have ordinary and extraordinary functions; their ordinary functions consist in preparing various matters of discipline and finance for the final settlement at the conference, and also in the preparatory examination on given subjects of candidates for the itinerant work. When the district is assembled for the discharge of its extraordinary functions it is called a special district meeting; in this capacity it investigates charges against any of the preachers, and, if it sees fit, suspends them from their office until the ensuing conference. It is, moreover, invested with authority to settle all matters of dispute and strife which may arise in any of the circuits within its bounds, and appear sufficiently important to require its intervention, until the next annual meeting of that assembly.

But it was a much more easy task to settle the form of government, than to bring the people to understand the real situation of the Methodist body in respect of the established church, and to acquiesce in the general principles of government and administration which Mr. Wesley had provided for them. A party displayed itself both in the conference and the connexion, strong in numbers, enterprising in effort, and determined in resolution, who sought for the immediate and unconditional establishment of service in church hours, and the administration of the sacrament by their own preachers. They were firmly opposed, however, by another party, including in its ranks much of the real respectability and piety of the body, as existing both amongst preachers and people. These, adhering with unbending tenacity to the old plan, as it was called in the controversies of those days, strongly opposed what they thought to be dangerous innovations; their tenacity on these subjects was, in some points of view, far from discreditable to them, though it manifested a want of comprehensive regard to the spiritual wants of a widely extending population, for whose souls at that time only Methodism, on a large scale, cared, and alone was capable, by the special provisions of Mr. Wesley himself, of making an adequate spiritual provision for them. At the same time the party, wishing for the full developement of Mr. Wesley's plans and principles, seem to have been far from proceeding in their meditated designs for change in that cautious and temperate manner, which respect for his wishes, and even honest prejudices as a minister of the Church of England, ought to have inspired, and which was further needful to the rendering those changes as extensive a blessing to the connexion and the kingdom as their more judicious and enlightened advocates desired. Agitations on this subject prevailed for three or four years; at last, however, the conference made a pretty generally successful effort to reconcile these conflicting views by an act which was called the plan of pacification, which allowed, under certain circumstances, of the wished-for concessions. On this proceeding the Rev. Richard Watson thus very properly remarks in his Observations upon Southey. 'So far from Mr. Wesley's views and principles having lost their influence with the conference, the sacrament was forced upon none, neither was it recommended to be received from Wesleyan ministers, in preference to the clergymen of the Established Church. The old principles were held as fast as higher duties would allow, and the plan itself, adopted at once to meet a case of conscientious scruple, while it avoided encouraging a departure from the primitive mode; and leaving every individual to act as he was persuaded in his own mind, whether to receive the sacrament at church or meeting, has at length been cordially acquiesced in by both parties as equally warranted by principle and by prudence.'

While these disputes were going on in the connexion, and the conference for some years, as many thought very unreasonably and improperly, delayed the gratification of the wishes of a large proportion of the people, the power of that governing body itself came into discussion; and it is no matter of surprise that such should have been the case in those times of general ferment respecting power, liberty, and government, which mark the memorable epoch, and some of the early years of the French revolution. It was stoutly contended that the power of the conference was unscriptural, arbitrary, and dangerous; and, under this impression, that body received addresses from various quarters, to this effect. 'That the people might be represented in the conference by delegates, chosen by, and from amongst themselves; or that in future the conference might be composed of an equal number of preachers and representatives of the people.' This plan was alleged by its promoters to carry on the face of it, equity, harmony, and a pledge of future prosperity. It was not, however, acceded to by the conference; which, nevertheless, sought to meet the wishes of the people, and the real exigencies of the case, by important, and, as they deemed, effectual concessions, guarding against the abuse of the power lodged in it, and providing for the inviolability of rational and Christian liberty in the connexion. These additional regulations, limiting the exercise of power, and strictly defining the modes and circumstances of its exercise, are published in the minutes of the Leeds conference, A.D. 1797. This year was remarkable also for the formation of the Methodist New Connexion, based on the principle already stated. Important questions are involved in the leading ground of difference between the two connexions—questions which relate to abstract theories of government in general, and the practical application of those theories; and not merely to these, but to the principles laid down in the New Testament respecting the distinctive character, proper functions, and consequent power of the ministers or pastors of the Christian church. It is fair to observe that the preachers constituting the conference of the Old Connexion, deny altogether the imputations officially brought forward against them by the advocates of the new system, of a fixed jealousy and dis-

trust of the people, and a degrading estimation of their ability and assistance. On the contrary they profess themselves, for Christ's sake, the willing and devoted servants of the people; the advocates of the old connexion, indeed, allege that their system, as now modified, secures to the body at large all needful religious privileges and advantages, by provisions, as closely connected with leading principles of the word of God, and as well adapted for perpetuity of vigorous operation, in repressing tyranny and arbitrary power, as were ever comprised in any human institutions. When divisions take place in any community, it is, doubtless, the peculiar business of the dissentients to establish a clear case of justification, and this principle is especially applicable when differences in theory, rather than any palpable grievances in practical administration, constitute the ground of proceeding, which, whatever ultimate good may be expected to result from them, stand connected with immediate evils of no trivial amount, when estimated in their religious bearings. Whether the remark is applicable to the formation of the Methodist new connexion, is a mooted point which we shall not attempt to decide; it certainly, however, is a truth of too correct application to the ecclesiastical history of our own times, that separating measures amongst religious bodies are far too readily adopted, and the evils resulting from them, to the general cause of Christianity, much too lightly appreciated. The abstract right of separating from any existing Christian community ought to be strenuously asserted, and kept inviolably sacred; but persons in a truly Christian frame of spirit will most reluctantly resort to its actual exercise.

It is, on all hands, allowed that since the period now treated of the Methodist body has been governed on wise, moderate, and conciliatory principles; and a disposition has been extensively acted upon to associate the people with the conference in the direction, so far as financial matters are involved, of all the great affairs of the connexion. The highly important department of foreign missions is placed under the actual management of a committee, composed of an equal number of ministers and laymen, who meet statedly for the transaction of its affairs at the Wesleyan mission house, 77, Hatton Garden, London; but the details of the progress of this great institution, we reserve for a distinct article. It has already been observed that the distinctive character of Methodism is to be sought for, not so much in its doctrines, as in the application which it studiously makes of them to produce lively impressions and immediate results. The numbers also whom, by the zeal and earnestness of its ministers, it brings to more serious and influential views of religion than they have previously entertained, it immediately subjects to a course of discipline at once calculated to unite them with the system by closest ties, and to call forth all their energies in its support and propagation. Thus, in the system of Wesleyan Methodism, we find that there exist, in addition to its itinerant preachers or regular ministers and the leaders of its classes, local preachers, exhorters, and prayer-leaders: these latter functionaries are employed in various services, such as their names denote, on the Lord's days, but at other times follow the ordinary occupations of life. Whatever be the supposed advantages or defects of this system, it will easily be seen to be admirably adapted to radiate and extend the form of Christianity which it embodies, wherever its operation is allowed. It is therefore no matter of surprise that the Wesleyan Methodists should have been eminently successful in their missionary operations; that the societies in close connexion with them in the West Indies, and especially in British America, Ceylon, South Africa, Australasia, &c., should include such rapidly increasing numbers, and exert an influence so generally beneficent and quickening upon other forms of Christianity.

At an early period of the history of the connexion, the attention of Mr. Wesley was directed to the British colonies on the North American continent. While the large tract of country to the north, constituting what is called New England, was generally provided with the institutions of Christianity; in the southern and middle states there was no provision to meet the spiritual exigencies of a rapidly extending population. In these vast regions, therefore, Methodism, or some similar system, was much needed, and it has been eminently useful. The connexion in the United States is much more numerous, both in itself and relatively to the general population, than in the British Islands. There are some varieties also in its discipline and government, the most material of which is the episcopacy of the American connexion. An American Methodist bishop, however, as presiding in the conferences, is rather a primus inter pares, first among equals, than resembling an English diocesan, recognised of an order essentially and scripturally distinct from that of Presbyters. The government of the American connexion, then, approximates to the model of archbishop Usher's reduced episcopacy, while that of the English body is purely presbyterian.

The Rev. Thomas Coke, LL.D. of Magdalen College, Oxford, who united himself with Mr. Wesley about the year 1781, made several voyages to America, and being appointed by Mr. Wesley one of the first general superintendents, afterwards denominated bishops, of the Methodist Church on that continent, was principally concerned in fixing the subordinate details of its government, in conformity with the leading regulations of the Methodist system. Proceeding on one of his voyages from England to the United States, in company with some other preachers or missionaries, the vessel in which they had embarked was driven by stress of weather to the West Indian archipelago, and the Dr. with his associates was ultimately landed in the island of Antigua. See the next article. So it came to pass that, while the Methodist body was prosecuting its first great religious undertaking without the limits of the British Isles, its attention was, in this remarkable manner, directed to a sphere of exertion in which, next to the North American continent, its missionary efforts have been crowned with the largest measure of success, and more

perhaps than in any other instance, produced the most advantageous results to the community at large. It is true that, at first, the Wesleyan missionaries met generally with every species of opposition and even legal persecution, in such degree and for such times as the colonial legislatures and magistrates were capable of inflicting it. But the enactments authorising such proceedings have been uniformly disallowed by his majesty in council; and the beneficial operation of the labors of the missionaries upon the character of thousands of the slaves, has, in the course of years, succeeded to a considerable extent in disarming the prejudices of many of the planters, and in securing for missions, conducted on principles at once so energetic and so wise, the warm patronage of many persons of respectability and influence, both in the colonies and at home.

For statistic details respecting the numbers in society, &c., on Wesleyan missions we must refer to the Minutes of the last conference: it may be proper to mention that the government on missionary stations is the same in form with that established in the connexion at home; but it is necessarily provided that there should exist a connexion more or less strict and immediate, according to circumstances, with the committee of management in Hatton Garden, whose proceedings are subjected to the final control and supervision of the conference.

The following is the 'General Recapitulation' of the conference of 1827.

		Nos.
Number of Members in Great Britain		237,239

It has not been our particular object, in this article, to present our readers with facts which in their proper details, as constituting parts of the regular history of Methodism, may easily be collected from any of the works professedly treating on the subject; but our design has rather been to furnish our readers with means for forming correct views on the peculiarities of this remarkable system. These appear to be but very imperfectly understood by the intelligent public of Great Britain. Their attention, indeed, is justly called to a system which alleges itself to be admirably adapted to varying places and circumstances; which is in one place merely a religious society, but in another place, where circumstances differ and seem to call for it, a proper and complete church; and which, in every mode of its existence, presents itself to all lovers of Bible Christianity, as adapted to promote their religious advantage in any way, and to any extent, that they may think fit to avail themselves of its aid.

We are indebted thus far for a sketch of Methodism to an able member of that community. Dr. Southey's late life of Mr. Wesley has brought forward the subject in circles where a living Methodist would be thought to spread a sort of contagion; and as his biographer is quite sure that Methodism frequently produced a bodily disease, 'peculiar and infectious,' we suppose that many persons will prefer to remain acquainted with it solely through the medium of books. For their sakes, and in justice to the poet laureate, as well as to one branch of Methodism that has been less under the observation of the candid writer of the foregoing sketch, we avail ourselves of some original observations on Dr. Southey's work which have already appeared in a deceased periodical, but which seem highly relevant to this interesting portion of modern ecclesiastical history.

'The name and character of Mr. Wesley,' says this writer, 'must ever occupy a large space in the religious history of the last century: but Methodism, which Mr. Southey has indefinitely associated with them, is often a very distinct subject. It will include the biography of Mr. Wesley as the founder of its more organised branch; but his history is by no means that of the singular revival of religion in England which has generally been designated by this name. He was but one of its great leaders and agents, who finally gave a distinct and permanent form to his work. The fruits of Mr. Whitfield's preaching in England, though it was of much shorter continuance than that of the Arminian leader, are to the present day, perhaps, at least equally extensive. In this country the Calvinistic Methodists are said nearly to equal the Wesleyans in number, and in Wales very considerably to exceed them. A succession, moreover, of regular clergymen, whose numbers have largely increased since his death, has been found to advocate the sentiments, and emulate the efforts, of this extraordinary man in the establishment. Like Toplady and Romaine, they are more scrupulous of trespassing upon order, and more cautious of their associates, than was Mr. Whitfield; but however they may have been improved, in modern times, by experience or by opposition, the

evangelical clergy were called into being by the example of this great founder of Calvinistic Methodism, a circumstance that adds considerably to its pretensions as a subject of history.

'We are now speaking merely to a few general facts of this theme.—The rise of Methodism was a revival of religion in England, whatever have been its irregularities and extravagancies. Since the Reformation there had been no efforts for religion equally extensive; no preaching so little sectarian; no preachers with equal claims to being the μαρτυρες of the faith. Churchmen and Dissenters were aroused from a common religious slumber by Methodism; it 'came up on the breadth of the land,' with a sound and a power to awake the dead. Could no other proof of this be adduced, Dr. Southey himself tells the world how much of the entire momentum of its modern zeal the established church, in particular, owes to Methodism. He observes, 'it may perhaps be said to be most useful' [as a stimulant, we suppose] 'where it is least successful' [as a sect]. Be it so. Never, we believe, was there a high church party in an establishment so truly anxious to sustain itself by argument, as modern times have seen in England;—by spiritual, rather than by temporal means. Never, for instance, so nobly zealous for the education of the poor, which will of itself outgrow any thing of a sectarian spirit that now mingles with it; and we hail, for our country, the more cheering aspect of beholding her dignified churchmen thus engaged, rather than in the low intrigues for the interests of tyranny and intolerance, in which some of them could associate even with infidels in the latter days of queen Anne. Methodists, however, led the way into this noble field of exertion; for Methodism awoke the established church to the value of public opinion, and dissenters to the importance of bold and united efforts of Christian zeal. * * * But Methodism, in its systematic form, soon grew too strong for a dependent, or even an auxiliary power. Opposition taught it its own resources; the contempt of some of the more enlightened classes of society happily united in throwing its light into the darkest corners of the realm; and in developing funds, talents, and powers, among the lowest orders of the people, to which statesmen and moralists had been alike blind for ages.

'Of the two leading *systems* of Methodism,' adds this writer, 'as they were left by their founders, our readers will judge according to their own habits and connexions; and many will attach a degree of importance to the doctrines in controversy between them with which no other part of either system, no better or worse modification of church discipline, will be thought to compare. Others will hail that which is at once common to both systems, and ever suited to the wants of a fallen creature—a testimony to the necessity of a change of heart in all men—as a light from heaven! The existing state of religious parties in England, at the period of the dawn of Methodism, will render this, we should be disposed to contend, the redeeming point of its early history. This, at least, was plainly preached throughout the land. Did it awake a thousand jealousies and evil passions, because it disturbed the profane in their works of darkness, and the pious in their dreams? Did it break through clouds, and call up clouds of error and enthusiasm, on its first appearance? Still it was the light of life. Angels minister the law no more. Every great moral reformation of mankind, since vision and prophecy have ceased, seems destined, by its innovations, its irregularities—and by some one capital feature of divine wisdom and simplicity pervading it—at once to attest its almighty author, and that he employs but human agents in its accomplishment—but ordinary human agents, as compared with the primitive teachers of Christianity. See the beautiful imagery of the Apocalypse, chap. xxi. 14–16. The reformation of Protestant Europe in the fifteenth, and of England from semi-popery and infidelity in the eighteenth century, both proceeded in this way. The one proclaimed its justification by faith, as the articulus stantis vel cadentis ecclesiæ; the other our Saviour's own introductory message—'Ye must be born again:' and each had its qualifying mixture of human imperfection and real fanaticism about it. The reformers could persecute, and the Methodist leaders throw their hearers into convulsions, and take pleasure in the success of their measures. We need not enquire which was the greater error.

'Are neither Whitfield nor Wesley entitled to be placed on an exact level with Martin Luther in history? Had they less general steadiness of character, less comprehension of mind, less caution? We must think so. But they were noble spirits, with all their human frailties. John Wesley would have done more for the highest interests of man, without the assistance of a Martin Luther, than Philip Melancthon; and with a Knox, a Zwingle, or a Bucer, the Methodist leaders may be honorably compared. The great peculiarities of the Christian faith, which they kept always in view, were singularly like the cardinal points of Luther's doctrine and early efforts. 'He pointed out the distinction between the law and the gospel,' says Melancthon; 'he refuted the Pharisaical error, at that time inculcated both in the schools and in the pulpit, that men may merit remission of sins by their own works, and become righteous before God. Thus he directed the minds of men to Jesus Christ; and, like John the Baptist, pointed to the Lamb of God who taketh away the sins of the world.' Could any language more aptly describe the state of religion in England at the period of which we are writing, and especially in that church in which the champions of Methodism arose? Some of the most popular sermons of the day, those of Atterbury, taught, 'That the virtue of charity [i. e. alms-giving, or at most a truly benevolent disposition] is of so great a price in the sight of God, that those persons who possess and exercise it, in any eminent manner, are peculiarly entitled to the divine favor and pardon, with regard to numberless slips and failings in their duty, which they may be otherwise guilty of: this great Christian perfection, of which they are masters, shall make many little imperfections to be overlooked and covered; it shall 'cover the multitude of sins.' What Melancthon proceeds to say of Luther might be

almost transcribed, word for word, into the history of either of these great Methodists. 'This revival of important truths procured him a very extensive authority, especially as his conduct corresponded with his instructions, and they proceeded not merely from the lip, but from the heart. This purity of life produced a great effect upon the minds of his hearers, and the old proverb was verified, Σχεδον, ὡς ειπειν, κυρωω τα την εχει πιστιν τὸ ἦθος. 'Piety makes the speech persuasive.' Wherefore many worthy men, influenced by the excellence of his doctrine and the sanctity of his character, were afterwards induced to comply with some of the changes which he introduced in certain established ceremonies. Not that Luther at that time meditated an innovation upon the customary observances, or broached any alarming opinions; but he was illustrating more and more the doctrines so essential to all, of repentance, the remission of sins, faith, and salvation by the cross of Christ.'

'Mr. Southey is evidently partial to Wesley: —he admires, but he neither loves nor venerates him; he reminds us of Erasmus's good opinion of Luther. 'God had sent him to reform mankind,' he owned, 'and the man's sentiments were true; but his course was invidious, because he at once attacks the bellies of the monks and the diadem of the pope. It grieved him that a man of his fine parts should be rendered desperate by the mad cries and bellowings of the monks.' The poet laureate may not thank us for the compliment; but we see very much of his temper respecting Mr. Wesley, as a whole, in the epistles of Erasmus to the elector of Saxony, and others respecting Luther. What said the reformer to all this? Just what a sensible Methodist might say to our biographer. 'I shall not complain of you for having behaved yourself as a man estranged from us, to keep fair with the Papists, our enemies. Nor was I much offended that in your *printed books*, to gain their favor, or to soften their rage, you have censured us with too much acrimony. We saw that the Lord had not conferred upon you the discernment, the courage, and the resolution to join with us—and therefore we dare not exact from you that which surpasses your strength and capacity. We even bear with your weakness, and honor that portion of the gift of God which is in you.' Luther's Letter to Erasmus, in 1524.

'For Mr. Whitfield, Mr. Southey has not even the cold and inconsistent admiration he expresses towards Wesley; and from Calvinism he is bigotedly averse. Having quoted from Mr. Wesley what he calls the sum of all that Zanchius and Toplady had said on predestination, our impartial biographer adds—'This is the doctrine of Calvinism, for which diabolism would be a better name; and, in the *worst* and *bloodiest idolatry* that ever defiled the earth, there is nothing so horrid, so monstrous, so impious as this.' (Vol i. p. 371). And this is 'neither extenuating or exaggerating any thing;' this is Mr. Southey's 'accuracy' in reporting on a controverted subject; Mr. Southey's 'sense of duty!!'

Some of the 'American Methodists,' not connected we believe with the episcopal and regular body, are called Camp Methodists, among whom are found the lesser tribes of Shakers, Jerkers, Rollers, Jumpers, &c.

METHODIST MISSIONARY SOCIETY.

METHODIST MISSIONARY SOCIETY. The missionary exertions of this large and respectable body of Christians were not reduced to system, nor were societies regularly organised for their support, until the year 1817. Yet missions to the heathen were commenced and superintended by the late Rev. John Wesley, founder of this religious community, and Dr Coke, one of its most useful and laborious ministers. As early as 1769 two missionaries were sent out to North America, and during the two following years four more sailed from England for the same country. In 1786 Dr. Coke and three other preachers were proceeding to Nova Scotia, but being compelled by stress of weather to steer for the Island of Antigua, and meeting with a very kind reception from the inhabitants, they considered these circumstances as a providential call to establish a mission among the negro slaves in the West Indies. Here too the way had already been paved for this effort of benevolence; for in 1769 Nathaniel Gilbert esq., who had experienced the power of religious truth in England, became a resident of this island, where he soon directed his attention to the spiritual welfare of its inhabitants. He first assembled a few persons together in his own house; and, finding his exertions eminently blessed, notwithstanding the situation he held as speaker of the house of assembly, he went forth boldly with a truly primitive zeal and holy courage, and preached the gospel to the poor negroes. 'A mode of conduct,' says Dr. Coke, 'so unprecedented in an exalted character soon excited surprise, surprise was followed by disapprobation, and disapprobation settled into reproach and contempt. Regardless, however, of the insults of those whose applauses he had not courted, he continued to persevere, and soon perceived he had not labored in vain. From among the number who attended on his ministry about 200 were joined in society, and manifested by their lives and conduct that they knew in whom they had believed.' The labors of Mr. Gilbert terminated but with his life; and, as he had no means of appointing a successor, his bereaved flock were left as sheep without a shepherd for a period of nearly twenty years. In 1778 Mr. John Baxter, a member of the Wesleyan connexion in England, removed to Antigua as a shipwright in the service of government. This good man took upon himself the care of Mr. Gilbert's society, and devoted all the leisure he

could command to the spiritual good of those around him; 'his usual method,' says one who has recorded the interesting tale, 'was to travel in the evening to the different plantations where the negroes were assembled to receive his instructions, and, after affectionately warning and exhorting them, he returned home, through those heavy dews which are so pernicious between the tropics, that he might be ready for the business of the ensuing day.' Thus, like a primitive apostle, while his own hand ministered to his necessities, he regarded not even his life to supply the lack of service to these destitute and friendless people. Through his superintendance, the assistance of Mrs. Gilbert, and the subordinate instrumentality of an old Irish emigrant who had come to the island in 1783, things went on so prosperously that they had had in their care upwards of 1000 members, chiefly blacks, who appeared anxious for all the blessings of our common Christianity. Many new places were opened for preaching, and the demand for instruction far exceeded the supply; losses were repaired by new admissions, and many happy deaths took place which demonstrated the power of the Christian faith and hope to animate the mind in that most solemn hour. In January, 1787, Dr. Coke resolved that Mr. Warrener, one of the missionaries originally appointed to Nova Scotia, should remain in Antigua, and Mr. Baxter resigned his lucrative situation as under store-keeper to devote himself entirely to the work of the ministry. In 1789 Dr. Coke again visited Antigua, and found 1000 members added to the society; and his testimony to the religious character and habits of the converted negroes deserves to be recorded in such a sketch as this. The Dr. observes 'Our blessed Lord, before he quitted for heaven, gave to his followers a new commandment, namely, that they should love one another, and perhaps we can find but few places in which this command has been more punctually obeyed than in Antigua. In times of sickness the members of our society visit each other with the most affectionate solicitude; in those cases where medical assistance is required by a patient who is unable to provide for it, it is instantly procured without any regard to expense. It may, indeed, be said that they live like brothers; that they are pitiful and tender hearted, and melt in sympathy at each other's woe.' A second visit (1790) amply confirmed the expectations of prosperity which this station had induced. In 1797 a missionary named M'Donald was sent out for Antigua; he encountered some very severe trials, when about ten leagues off Antigua they were attacked by a French privateer, captured, and confined about three weeks till an exchange of prisoners brought him aboard an English ship. Here the captain was desirous to secure his services as chaplain; but, this proposal being incompatible with his previous arrangements, M'Donald was put on shore in the island of Dominica, whence he gained Port Royal in Martinico. After a variety of sufferings and deprivations, he sailed to St. Pierres, and thence under convoy of an English privateer he arrived safely in St. John's harbour in Antigua. The death of Mr. Baxter took place in November 1805, and his remains were interred in the chapel. This event occasioned a temporary derangement of the affairs of this mission; the missionaries, however, were enabled to keep their ground, and in the course of a few years much good was done. They were, however, obliged to send repeatedly to England for additional aid, and more laborers. In April 1816 the island of Antigua was placed under martial law, in consequence of an insurrection which had broken out in Barbadoes; on this occasion Mr. Wooley, one of the missionaries, in company with his colleagues, went to the president and offered their services in any way that might be deemed serviceable to government. The reply was, an expression of thanks for the loyal offer, and an assurance that they could render more important service than that of bodily exercise; to which they in return assured him that their efforts should be directed to remove any unfavorable impression which the painful report might have induced to the prejudice of pure and undefiled religion. The close of the year 1818 proved an unusually sickly season; and Mr. David Jones, an excellent and promising missionary, was removed by death from the sphere of duty. In 1819, 1820, and 1821, we have, from authentic sources, accounts of the prosperity of the Antigua Sunday schools, confirmed by striking facts,—of the noble liberality of the inhabitants towards the erection of new school rooms, as the two in the town of Parham had been destroyed by a hurricane; and the formation of a missionary society in St. Johns, towards which the subscriptions and collections amounted to about £93, exclusive of trinkets which were offered towards this good work; this was soon followed by a branch missionary association in English Harbour, in which the negroes took a deep interest. The close of 1821 was marked by the conversion of a Mahometan negro, who was publicly baptised and renounced the delusions of the false prophet. In September 1822 a new place of worship was opened at Sion Hill; it had been erected by the proprietor, the Hon. J. D. Taylor, for the benefit of his negroes. The Christian benevolence of this excellent individual is thus noticed in the account of Mr. Whitehouse, one of the preachers:—'Among these negroes they appear rather as parents than proprietors; the sick are fed from their table, and they are building a hospital for lying-in women almost close to their own house, that Mrs. Taylor may have an opportunity of seeing them several times in the day.' In December Mr. Whitehouse laid the foundation stone of another chapel, in Willoughby Bay: on this occasion the Moravian missionary and his wife were present, together with several gentlemen from the different estates; and the negroes connected with the congregation of the Moravians at New Field brought a contribution of several loads of stones, some of which were already squared for use. The Annual Report of the present society for 1824 speaks of the divisions of this station, St. John's, English Harbour, and Parham, as generally prosperous and encouraging.

St. Vincent's.—In January, 1787, a pressing invitation induced Dr. Coke and three of his brethren, Messrs. Baxter, Clarke, and Hammet,

to visit this island. They were cordially received, a large warehouse was fitted up in Kingstown, and a promise given that the negroes should attend; rooms were appropriated for Mr. Clarke's use, who was to remain here; and the president of the council kindly permitted the use of the court-house, every Sabbath, for divine service. The negroes expected so much personal benefit from these new comers, and were so delighted with their visit, that some said, 'these men are imported for us.' In January Dr. Coke and the brethren left St. Vincent's, and Mr. Clarke remained to commence the labors of the Christian ministry; and on a second visit, in 1788, this mission presented a very favorable appearance. On this occasion Mr. Clarke accompanied the Dr. and his friends on a somewhat perilous journey to the Caribbean country, where Mr. and Mrs. Baxter took up their residence, but were eventually obliged to hasten from this department of the island through the fears and prejudices of the natives, who treated them as spies sent by the king of England to explore their territories. Amongst this people Mr. Baxter labored in vain, and failed to impress this roving people with the concerns of salvation; in the English division of the island the prospects were favorable. Two additional missionaries were appointed, and pursued their important work till 1792, when the secular arm interposed most unjustly to prevent the instruction of these poor negroes. A law was enacted, requiring a licence for all preachers, and twelve months' residence in the island was required to render the applicant eligible. From the plan of itinerating from place to place they knew that this law would effectually operate against the society's missionaries. For the first offence the punishment was by fine or imprisonment; for the second corporal punishment at the discretion of the court, and banishment; and finally, on return from banishment, death. This atrocious measure was hurried through the assembly, and very obnoxious to the people at large. Mr. Lamb, a missionary, was a victim to this oppressive enactment; he was seized and imprisoned, but afterwards released. On the return of Dr. Coke to England he presented a memorial to his majesty in council; enquiries were instituted; the reports were highly favorable to the character and conduct of the mission, and the act of the assembly was disannulled. 'Thus,' says the Dr., 'did religious liberty triumph over the private endeavours of oppressive violence, through the goodness of a king enthroned in the hearts of his people.' In 1794 this mission was renewed in the persons of Messrs. Owens and Alexander and their successors, who found ample employment, and pursued their course through evil and good report; through the difficulties and dangers which the habits and acts of this uncultivated people necessarily opposed to the promulgation of pure and primitive Christianity, of which wars with the Caribs, and an intolerant and persecuting spirit amongst the islanders, were the principal causes. 'Yet,' as one of the missionaries observes, 'notwithstanding these hindrances, God vouchsafes to convince the poor Africans of sin, and savingly converts them to himself; and some of them die, not only with a hope of heaven, but triumphing in full assurance' In the autumn of 1804 the West India Islands were visited by two tremendous storms of thunder and lightning: the door of a magazine, in Fort Charlotte, was wrenched open by the lightning, and, but for the interposition of divine providence, Kingstown, with all its inhabinants, would have fallen a sacrifice: for several hundred barrels of gunpowder were at the time in the fort. In 1815 the three missionaries, resident in St. Vincent's, took up their stations in three different parts of the island, and at this time the society consisted of about 800 members, all slaves. A recent insurrection in the island of Barbadoes furnished a pretext to the enemies of the gospel to bring the missionary system into discredit; and in 1816 the legislature intimated their intention to embarrass the mission; but the session passed without the adoption of any such measures. From this period to 1824 the intelligence received is favorable; and, during that year, 226 new members were admitted, and thirty-eight remained on trial as candidates for similar privileges.

St. Christopher's.—This mission commenced in January 1787. By a visit which Dr. Coke and others paid to the island great benefits were soon apparent from the introduction of the Gospel. In 1802 the members amounted to 22,587. In 1824 a branch missionary society was formed, on which occasion William Warton Rawlins, speaker of the house of assembly, presided; and in January 1825 a new place of worship was opened in the town of Basseterre, when his excellency the governor contributed to its erection, and, with his suite, attended at its dedication.

Barbadoes.—In December 1788 the indefatigable Dr. Coke directed his attention to this island, where, from his reception and other favorable circumstances, he anticipated for the mission a favorable prospect of success. Mr. Pearce, who accompanied the Dr., commenced his labors; but was soon exposed to violent opposition. Mobs were collected to disturb the worship, and volleys of stones were thrown against the doors; an appeal to the authorities led to the singular decision, that, as the offence complained of was committed against Almighty God, it was not within the jurisdiction of the magistrate! Thus were the assailants secretly encouraged; but a second application led to the apprehension and punishment of five of the rioters. This circumstance did some good, but the disaffection to the missionary labors exhibited a gloomy prospect for several years. In 1816 an insurrection broke out among the negroes: and this was falsely attributed to the preaching of the missionaries. The report of the committee, however, as might be expected, traced this mischief to far different causes. About the year 1820 the prospects began to improve. In 1821 an auxiliary society was instituted; and the friends of souls gradually surmounted opposition. In June 1822, at the anniversary of the missionary society, the chapel was overfilled; the collections doubled that of the preceding year, and even some Jews gave their silver and gold to further the good work. The sun, however

bright as it was, suddenly became eclipsed; and, about three months subsequently to this pleasing scene, a storm, which had long been gathering, suddenly burst with destructive fury. From personal abuse, and sinister encouragement, the populace proceeded to open violence; and, not contented with attacking the chapel, placed the lives of the worshippers in jeopardy. After the missionary had resided three years and a half in the colony, he was summoned to answer for not having enrolled himself in the militia; a petition to the council met with no attention; and, in the course of that very week, the mob levelled the chapel with the ground, and the poor servant of God and his family were compelled to escape to St. Vincent's to save their lives. After the departure of the principal persons the members of society who were left became the objects of lawless aggression. The destroyers of the house of God, says a minute historian of these transactions, on the 19th of October, 1823, resolved to celebrate the anniversary of the demolition of the chapel in honor of their signal triumph over methodism, and determined to end the anniversary by razing the dwelling house of one who yet dared to uphold this obnoxious system; and an appeal to the authorities led to the prohibition of any such meetings in future; while it protected the intended victim from the threatened outrage by the interposition of constables. Soon after these disgraceful scenes Mr. Buxton, the member for Weymouth, spontaneously brought the subject under the consideration of parliament; and, although Mr. Canning did not consider it advisable to adopt Mr. Buxton's resolution, the amendment which he substituted embraced all the strong points of the original motion, and was carried nem. con. This declaration of indignation by the British parliament, at such daring violations of the law, may be considered preparatory to the free enjoyment of religious worship, and the rights of conscience; and impose a powerful restraint on such rash acts of bigotry and intolerance.

Dominica.—In 1788 Mr. M'Conock was left in this island by Dr. Coke with a sufficient probability of success; but he fell a sacrifice to a malignant fever. Several missionaries followed in succession to this scene of labor; and in 1813 Mr. Willis, who was appointed to this station, narrowly escaped the effects of one of those hurricanes so common in this part of the world. In 1816 Mr. Boothby commenced his labors in Dominica; and, although he found things in a discouraging situation, his exertions were crowned with success. But his career was short; for, during the same year, he fell a victim to a severe cold, which, in ten days, destroyed his life. He had been well received by the inhabitants in general; and the governor of the island, with many other gentlemen, followed his remains to their last earthly resting place. In 1822 the earl of Huntingdon assumed the government of this island, and became the zealous patron of all attempts to better the moral condition of the people, and instruct the negroes in the truths of Christianity. In October of this year his excellency and suite, with many of the authorities, civil and military, were present at laying the first stone of a new Methodist chapel in Roseau. This chapel was opened in May 1823 under similar auspices. In 1824 Mr. Felous was zealously employed in instructing the negroes of the island of St. Joseph, where Roman Catholic superstitions are very prevalent. The recent intelligence is, that the new chapel in Roseau is well attended; that at St. Joseph there is an increase of members; and that, generally, the Dominica mission is in a prosperous and satisfactory condition.

Tortola.—Missionary exertions commenced in 1789, and Mr. Hammet was appointed to divide his labors between this and the adjacent islands of Santa Cruz, till other preachers should arrive from England. The preachers sent out to this part of the world are spoken of in high terms with regard to their loyalty, and the good effects of their labors on the minds of negroes, if considered only in a political point of view. In 1796 a Wesleyan chapel was erected in Spanish Town, and success followed the promulgation of the Gospel. In 1799 Messrs. Murdoch and Stengem were obliged to suspend their labors from illness. During this interval some irregularities appeared, and a spirit of insurrection broke out among the slaves; which, as usual, was laid to the charge of the instructions they had received. The missionaries, however, completely exonerated themselves. In 1804 Mr. Brennel succeeded Mr. Murdoch; but withdrew, in 1806, in consequence of a furious and brutal outrage, to which a faithful delineation of the character of these people, written to the directors in England, and the contents of which were known in Tortola, had given rise. In 1807 his colleague Mr. Evans died; and, in December, Mr. Hodgson succeeded him in his useful labors. The gratitude with which he was welcomed evinced the sincere attachment of the people to the ministry of the gospel. The effect of instruction on the morals of the slaves was strikingly beneficial. In speaking of the savage barbarities and impurities which were common among the negroes, it is added, in reference to a dance of a luxurious character: 'This diabolical custom is abandoned, and many of the slaves, who have received the truth in sincerity, relate, with feelings of horror, the part which they formerly bore in these detestable transactions.' A Sunday school was established on the Lancasterian plan, and made very considerable progress. In 1819 this mission suffered severely from the effects of a violent hurricane; all the chapels but one were destroyed, and the general loss of property was estimated at £100,000. When the news arrived in England about £2500 were liberally contributed to their relief, and the chapels were soon rebuilt. In 1823 a missionary auxiliary society was formed in Roadtown; and in 1824 the anniversary was honored with the presence of the president of the island and others, who not only contributed of their substance, but took an active part in the business, and appealed to known and authentic facts in support of their advocacy on behalf of the utility of missions in the West Indies.

Jamaica.—The mission to Jamaica commenced in 1789; Dr. Coke preached a few

times, and his account of the people is, that iniquity prevailed in all its forms; at the beginning the laborers in this vineyard had much to endure from persecution, opposition, and fatigue; abuse of all kinds was resorted to; but the fury abated gradually, and painful suffering was succeeded by useful and effectual exertion in the great and beneficial cause of pure Christianity. In June 1795 a dreadful conflagration broke out in the town at Montego Bay, on which occasion, though surrounded with symptoms of utter desolation, a man was heard to swear most profanely. A negro, who had listened attentively to the blasphemy and impiety, suddenly exclaimed, Oh Massa no use to curse and swear now, cursing and swearing do all dis! a conclusion worthy of the clearest intellect and the most pious Christian. In April 1797, when a subscription was set on foot to assist the mother country in carrying on the war, the members of various societies raised among themselves £150 in token of their duty and loyalty, and both whites and blacks, slaves and freemen, manifested equal zeal in the necessary exertions which this important crisis demanded. In the spring of 1802 some local preachers visited a village called Morant Bay, and, finding the people well disposed, formed a small society. The enemies of religion attempted to put them down by representing the preaching houses as nuisances, but in vain; the meetings were therefore continued with unabated zeal.

An event occurred at the close of this year which was productive of great evil, and arose from the wish to close at once all avenues of religious instruction to the slaves of this island. The legislative assembly passed a law, forbidding any but qualified persons to preach in any congregation of negroes or people of color, under severe penalties of fines, imprisonment, and hard labor. In Morant Bay Mr. Williams became a victim of this oppressive enactment, and at Kingston, Messrs. Campbell and Fish, supposing themselves shielded by their English licenses, continued their public labors without interruption, but when Mr. Campbell went to preach at Morant Bay he was committed to prison. The rigor, says Dr. Coke, which was aimed at by the new law, defeated the purpose for which it was passed, an application to the throne caused it to be forthwith disannulled; it had completely silenced all the local preachers, who returned to their labors with renewed vigor on its repeal. In Kingston an ordinance was passed by the corporation, which, although it recommended the instruction of slaves in the doctrines of the established church, prohibited the Wesleyan missionaries from teaching them by fines of £20 for every slave proved to be present at their meetings. The chapel was by these temporary and oppressive measures closed for several years. In 1815 it was re-opened by Mr. Shipman, who succeeded in obtaining a license, as did other of the society's missionaries, and in 1818 a second chapel was opened in Kingston, and licensed by the magistrates. The effects of divine truth on the slaves was soon obvious and beneficial. Their free countrymen, however, were too much wedded to their superstitions to reap a similar advantage. In 1821 this mission sustained a heavy loss by the deaths of two valuable missionaries, one of whom had spent eighteen years in the West Indies. Since this period several new stations have been added, as Port Royal, Stoney Hill, St. David's, Bath, Manchioneal, St. Ann's Bay, Bellemont, Goshen Estate, Guy's Hill, and Grateful Hill, and it is gratifying to learn that the congregations are numerous, the spirit of hearing very considerable, and the conduct of the people ornamental to their Christian profession.

Bermuda.—In 1798 application was made by a benevolent individual for a Wesleyan missionary, and in 1799 Mr. John Stephenson, a native of Ireland, proceeded from Dublin, through New York to this spot. He was met by the foolish prejudices of the inhabitants, who concluded as he was an Irishman he must be a rebel; this feeling gradually decreased, and in 1800 an increasing congregation and a new chapel were the pleasing proofs of the value of his services. Here, again, in a short time an obnoxious law, similar in its character to those noticed above, confined this servant of God in prison, brought him to trial and the alternative of fine or a long period of incarceration. An offer of liberty was subsequently made on condition that he should quit the island within sixty days, which he nobly spurned, and continued voluntarily a prisoner till the close of his allotted period. His health was hereby seriously undermined, and, as the legal valedictions prevented his labors, he was recalled in 1802. Here, again, an appeal to the good sense of his majesty's government at home led to the repeal of the obnoxious act, but the hostility of the people still continued. In 1808 another effort was made, and Mr. Marsden eventually succeeded in having a chapel erected, and a congregation established; and in 1811 the circulation of Bibles and tracts produced a mighty and pleasing moral transformation. In 1824 an admirable and just eulogy was pronounced on the missionaries of this society, at the annual meeting of the auxiliary society held at Hamilton in May, by the Hon. J. C. Eston, chief justice of the island, who presided on the occasion. 'I will maintain,' said he, 'that your missionaries in the scene of their operations, of all others the most interesting to us, I mean the West Indian colonies, have entitled themselves to the thanks of the established church, which they cannot without being calumniated be accused of undermining.'

Bahama Islands.—Mr. Turton, a West Indian, began to preach to the inhabitants of these islands in October 1801, and before the end of the year a chapel was opened in the eastern district with permission to instruct the slaves; he had to meet the frowns of the established clergy, but diligently persevered till 1804, when Mr. Rutledge arrived as his coadjutor; the sphere of their labors comprehended the adjacent islands of Exuma and Eleuthera. In 1811 the arrival of Mr. Dowton extended this sphere to Harbour Island, Abaca, and Providence Island: multitudes attended and much good was done. In 1816 a prohibiting edict interposed, and con

tinued in force about four years, but was afterwards repealed, when the missionaries became successful and the congregations increased. In 1824 a dreadful hurricane produced a most afflicting and calamitous scene in these islands.

St. Domingo -This mission may be dated from the year 1816, wnen Messrs. Brown and Catts were sent out to Port au Prince, the capital of Hayti in St. Domingo, an intimation having been received that the Protestant missionaries would not only be tolerated but patronised by government. In 1818 the prospects continued very encouraging; they had found access to the mountainous districts, and the congregations in the capital were very attentive, but in 1819 a reverse occurred, and they were obliged to quit a station where they had indulged the most pleasing anticipations of success; a party was formed to drive them from the island, although a military force was sent to protect them. His excellency the governor, however, thought for some reason that it was not expedient for them to preach any more; yet he gave a promise, since fulfilled, of presenting to the society a bill of exchange for £500 sterling. The missionaries removed from Port au Prince after two years labor, but left behind thirty approved members and eighteen on trial, under the care of two young men of promising talents. This society continued stedfast in their profession, but the spirit of persecution still continued, and many suffered much for the cause of their master; in 1824 we hear that this persecuted body had increased to ninety, and, although not allowed to hold public meetings for worship they continued stedfast.

In addition to the stations already noticed Wesleyan missions have been established in the islands of St. Eustatia, Nevis, Grenada, St. Bartholomew, Trinidad, Anguilla, St. Martin's, Tobago, and Montserrat, and in the colony of Demerara.

Mission to the island of Ceylon.—The great and generous Dr. Coke had offered to defray the whole outfit of the first missionaries to Ceylon and India. He at length induced the Wesleyan conference to sanction his plan; and, regardless of his own advanced years, he determined to accompany the persons destined to this station. In December 1813 he embarked at Spithead with six missionaries, and the fleet in which they sailed arrived in safety at its destination; part of the brethren sailed in the Cabalva, and part in the Lord Melville. One of the missionaries had to commit his wife to the mighty deep, and a still heavier calamity was in reserve; the venerable friend and father of this little band was suddenly removed by an apoplectic seizure, and they were compelled to proceed on their voyage and to the scene of their anticipated labors bereft of him whose knowledge, experience, and paternal character, were so desirable. On their arrival at Ceylon they experienced the most gratifying reception from the governor, the chief justice, the commandant, and the senior colonial chaplain. At the suggestion of the governor they agreed to separate to Jaffna and Batticaloa for the study of the Tamul language, and to Galle and Matura for that of the Cingalese; and it was further agreed that they should each undertake the superintendance of an English school at their respective stations, as this would introduce them, give them influence, and furnish an effectual method of learning the native tongue. Messrs. Lynch and Squance on their way to Jaffna were treated with great kindness at Colombo, the seat of government; and to their care a convert from Mahometanism who had been recently baptised was entrusted by the government for religious instruction. Soon after their arrival they were requested to perform divine service in the Fort Church, and they subsequently established a Sunday evening and week-day lecture; this, with other circumstances of a favorable kind, rendered the commencement of this mission most auspicious. In July Mr. Ault proceeded to his station at Batticaloa, and found the inhabitants heavily afflicted with sickness: the heat was excessive, and no suitable residence could at first be obtained. Some friends provided him an abode. His encouragement was considerable, and his congregations good; and, being anxious to promote the interests of the idolatrous natives, he studied hard at the Tamul language, and soon commenced his itinerations amongst the native huts. Mr. Erskine was gone to his station at Matura, the English school was opened, and in the Dutch Church he had a small and attentive congregation: he prepared himself for his future work by close attention to the Cingalese language. At Galle Mr. Clough continued to perform an English service in the Dutch Church every Lord's day, and this infant cause was essentially benefited by the decided patronage of lord Molesworth, whose influence exerted both in public and private produced the most gratifying results; the military became attentive auditors of the sacred truths of the gospel, and the mission presented a pleasing aspect: the indisposition of Mr. Harvard having detained him at Bombay he did not reach Ceylon till February 1814. On Christmas day in this year an idolatrous priest of Budha, who had arrived at a firm conviction of the truth of Christianity, amidst the violent opposition of some and the affecting entreaties of others, who were his relatives, was publicly baptised in the presence of a large congregation, his name was Petrus Panditta Sehara. This event produced a powerful sensation, and the fact was inserted in the Ceylon Gazette with an appropriate introduction by the governor himself. On account of the illness of Mr. Ault, which soon after terminated his life, Mr. Harvard was stationed at Colombo: here the government seminary contained many Cingalese youths, who, from the knowledge they possessed of the English tongue, were selected by the missionaries as interpreters of religious truth to their countrymen: here a Sunday school was established, and, on the arrival of a printing press, several thousands of elementary works were put in circulation; and a new and handsome chapel was erected, to which the public authorities and the archdeacon generously contributed. A person known by the appellation of the Ava priest became a convert to Christianity, and after a suitable probation was baptised by the name of Benjamin Parks. In the summer of 1815 this mission was strengthened by the arrival of five other missionaries, who were disposed of as

follows: Mr. Calloway to Matura, Mr. M'Kennie to Galle, Messrs. Broadbent and Jackson to Trincomalee and Batticaloa, and Mr. Carver to Jaffnapatam. In 1816 a school was established at Negombo, about twenty miles from the seat of government; and in 1817 a school-house was opened at Colpetty.

An anxiety which had been long felt to introduce the gospel into the Kandian territories was gratified in the year 1819; and in 1821 Mr. Newstead was enabled, by permission of the lieutenant governor and the friendship of Henry Wright, esq., to commence a missionary establishment at Kornegalle, a place considerably advanced in the Kandian territory; the beneficial results were soon apparent, especially in the strict observance of the Lord's day. On the 30th of December 1821 the first place of worship in the Kandian kingdom was publicly dedicated to the worship of the Most High, in the presence of a large assembly; the Te Deum in Cingalese was sung, and produced a very solemn effect. During this year the mission at Trincomalee sustained a great loss by the death of a native teacher who had recently been converted from heathenism to Christianity; as his illness became serious his relations and friends brought the heathen instruments wherewith they were accustomed to perform the ceremonies for the sick; he begged them to forbear, saying, 'What have I to do with these? I am a Christian—I am going to my Saviour—O Lord Jesus save me.' The death bed of this Christian believer was powerfully instructive. The last accounts from the different stations in Ceylon are in the highest degree encouraging to all who are interested in the promulgation of the Christain faith.

Missions in South Africa.—The benevolent exertions of the Wesleyan community were directed to this quarter of the world in 1816. Mr. Barnabas Shaw having previously attempted, but without effect, to obtain permission to instruct the slaves at Cape Town, directed his attention, with the approbation of the governor, to the interior of Africa. About this time Mr. Sohmlen, an agent of the London Missionary Society, arrived at the Cape with about a dozen others, and encouraged Mr. Shaw to proceed in his undertaking, at the same time promising to render him all the aid in his power. In the beginning of September they left Cape Town, and met six Hottentots, who had come from Namaqua Kraal, a journey of between 300 and 400 miles, to seek for some individual who might teach them the way of salvation. Receiving this incident as a token for good they proceeded on their way; and, when they had arrived at Namaqua Kraal, Mr. Shaw was left by his companions, who took their departure, and with only his wife as a companion was thus isolated in a strange land, surrounded by heathens, and comparatively ignorant of the language of the people. He instantly commenced his work; he soon collected a small congregation, and in May, 1817, began to instruct them in reading and agricultural pursuits. In June he baptised ten of these poor Hottentots, who gave proofs of the sincerity of their faith. In 1818 Mr. Edwards joined Mr. Shaw, and brought with him from the committee in London a quantity of iron for implements of husbandry. Repeated calls from the perishing heathen around them to come and preach to them the everlasting gospel was a loud appeal for additional help. Permission was obtained from the governor to establish a new settlement among the Bastard Hottentots at Reid Fountain; and on the arrival of Mr. and Mrs. Archbell, they occupied this new station; this took place on the 10th of August, 1819. In the month of March 1820 Mr. Shaw undertook a journey to some of the tribes beyond the Great Orange River, to explore the interior; and returned to Khamies Bay, after an absence of fourteen weeks. The account of this town, as contained in the Missionary Reports, is highly interesting. 'In the spring of 1821, on the arrival of Messrs. Broadbent, Hodgson, and Kay, it was determined to extend the Mission; and accordingly Mr. Archbell and a Hottentot assistant were sent among the Great Namaques—Messrs. Kay and Broadbent to the Bootchuana country—Mr. Hodgson remained at the Cape, and Mr. Shaw accompanied a party of settlers to Salem in Albany, about 100 miles from Algoa Bay. Here the sphere of usefulness was so extensive, that Mr. Threlfall was sent out to his assistance. The next point to which our missionary, Mr. Shaw, directed his attention was a mission among the Caffres; and in August 1822 he set out with two other missionaries and an interpreter on a visit to king Geika. To one of the missionary stations in Caffreland was given the name of Wesleyville, in honor of the founder of the society; and here the work of the ministry and the instructions of the natives proceeded in a pleasing and prosperous manner. This mission was strengthened in the month of March by the arrival of Mr. Whitworth; and they commenced a journey to the Tambookie country, to ascertain the disposition of the several chiefs as to the object of their mission. Here they found several fine openings, which invited their occupation; and at a district meeting in Albany in May, 1825, Mr. Kay was appointed to this service; and in company with Mr. Shaw proceeded to visit the chief Islambic. His sons conducted our missionaries to a spot on the banks of the rivulet Umkangisa, the most eligible situation for their purpose, to which they agreed to give the name of Mount Coke, in memory of the great and useful laborer in the Christian cause—the Rev. Dr. Coke.'

Mission in New Zealand.—The Wesleyan missionary, Mr. Leigh, who had been for some time stationed at New Zealand, sailed from Sydney in January 1822 for New Zealand, with a letter of introduction from the Rev. Mr. Marsden to the Church Missionaries stationed here. His first object was to attain a knowledge of the language, and teach the natives to read English. He found the New Zealanders very docile and attentive. Here he observed with much sorrow the grossness and absurdity of their opinions with regard to the Supreme Being, and the nature of the human soul, and the blood-thirsty cruelty which prevailed in this region of ignorance; but he occasionally had to rejoice in the attention and apparent interest with which

they listened to his instructions. In April 1823 he visited Ho-do-do in Doubtful Bay, and held some conversation with the natives. On his return he was joined by three fellow-laborers from England; illness obliged him to return to New South Wales, and two alone remained at Wangaroa on the river Thames, whose situation was at times very painful. In 1824 Messrs. Bennett and Tyerman being sent as a deputation to examine the Otaheitan missions, called at New Zealand on their way to Port Jackson, and whilst the Endeavour, the vessel in which they had arrived, was lying at anchor in Wangaroa, their lives were placed in great peril, but were mercifully delivered from the hands of these barbarians. On their arrival at New South Wales they communicated the result of their observations to the Wesleyan Missionary Society in London. A communication from Mr. Turner the missionary, in March 1825, states that some friends belonging to the Church Missionary Society, having heard of the perils in which they had been placed by the conduct of the inhabitants, had visited the station and decidedly recommended their immediate removal to the settlement; but when this communication was sent, Mr. Turner says, 'we now think it will be best to continue at our post for the present and quietly wait for the salvation of God.'

It only remains to be observed that, in addition to these several stations of active missionary exertion, the Wesleyan Society have others still in operation, the principal are, in America—Canada, Nova Scotia, and Newfoundland; in Western Africa, at Sierra Leone. In New South Wales—Van Diemen's Land, and the Friendly Isles. In Asia—Palestine and Continental India. In Europe—Ireland, France, Gibraltar, and Malta. In some of these stations much good has been done, in others the grain which has been sown is apparent only in the blade, but promises by and by to produce an abundant and glorious harvest.

METHODIUS, a father of the church, bishop of Olympus or Patara in Lycia, and afterwards of Tyre in Palestine. He suffered martyrdom at Chalcis in Greece towards the end of Dioclesian's persecution in the year 302. He composed many works, in a clear and elaborate style, which were extant in Jerome's time. F. Combesis collected several considerable fragments of this writer, cited by Epiphanius, Photius, and others; and printed them with some of his own, together with the works of Amphilochius, and Andreas Cretensis, in folio, Paris 1644.

METHUSELAH, Heb. מתושלח, or Mathusala, or Mathushelah, the son of Enoch, was born A.M. 687, begat Lamech in 874, and died in 1656, being the very year of the deluge, at the age of 969, the greatest age attained to by any man. Gen. v. 21, 22, &c. See ENOCH.

METIS (μητις, wisdom). The mother of Minerva, daughter of Oceanus and Tethys, the wisest of gods and men. The *Palus Mæotis* takes its name from her; and her sanctuary, where she was worshipped as the Great Mother, was at the mouth of the Borysthenes.

METIUS (Adrian), professor of mathematics and medicine at Franeker, was author of several treatises on astronomy and geography. He died at Franeker in 1635.

METIUS (James), brother of Adrian, said by some to have been the inventor of telescopes with glasses, one of which he presented to the States General in 1609, was born in Alcmaer.

METIUS SUFFETIUS, a general of the Albans, who, proving treacherous to Tullus Hostilius, the third king of Rome, was torn to pieces by horses. See ROME.

METO, or METON, was a celebrated mathematician of Athens, who flourished 432 years B. C. In the first year of the eighty-seventh Olympiad, he observed the solstice at Athens, and published his cycle of nineteen years, by which he endeavoured to adjust the course of the sun and moon, and to make the lunar and solar years begin at the same point of time. This is called the golden number, from its great use in the calendar. Meton was living about 412 B. C., for, when the Athenian fleet was sent to Sicily, he escaped a share in that disastrous expedition by counterfeiting insanity.

METŒCI, a name given by the Athenians to such as had their fixed habitations in Attica, though foreigners by birth. The metœci were admitted by the council of Areopagus and entered in the public register. They differed both from the πολιται and ξενοι; because the politæ or citizens were freemen of Athens, and the xeni or strangers had lodgings only for a short time; whereas the metœci, though not freemen of Athens, constantly resided upon the spot whither they had removed.

METONYMY, *n. s.* }
METONYM'ICAL, *adj.* } Fr. *metonymie*; Gr.
METONYM'ICALLY, *adv.* } μετωνυμία. A rhetorical figure, by which one word is put for another, as the matter for the materiate; thus, he died by steel, that is, by a sword.

METONYMY. See ORATORY.

METOPE, in architecture, the interval or square space between the triglyps of the Doric frieze, which among the ancients used to be painted or adorned with carved work, representing the heads of oxen, or utensils used in sacrifices.

METOPOS'COPY, *n. s.* Fr. *metoposcopie*; Gr. μετωπον and σκέπτω. Physiognomy; the art, if such there be, of knowing the characters of men by their countenance. An unnecessary word, whatever we may think of the art.

METRE, *n. s.* }
MET'RICAL, *adj.* } Lat. *metrum*; Gr. μετρον. See METE. Speech or written language confined to a certain number and harmonic disposition of syllables; verse; measure; numbers: metrical, pertaining to verse or metre.

Abuse the city's best good men in *metre*,
To laugh at lords.
Pope.

The establishing *metrical* psalmody in England

was the consequence of the Reformation and our communication with foreign Protestants.
Dr. A. Rees.

METRE. See POETRY.

METRODORUS, a Greek physician, born at Chios, was the disciple of Democritus the philosopher, and the master of Hippocrates the physician, and Anaxarchus the philosopher. He maintained that the universe was infinite and eternal; but his works are lost. He lived about 444 B.C.

METRODORUS, a celebrated philosopher and painter of Stratonice, who flourished about 170 A.A.C. Paulus Æmilius, after defeating Perseus, demanded of the Athenians a philosopher to instruct his children, and a painter to paint his temples; upon which they sent him Metrodorus, who satisfied him in both characters.

METRONOMII, the name given by the Athenians to five officers in the city and ten in the piræus, whose duty it was to inspect all sorts of measures, except those of corn.

METROP'OLIS, *n. s.* } Fr. *metropole;*
METROPOL'ITAN, *n. s.* & *adj.* } Lat. *metropolis;*
METROPOLIT ICAL. } of Gr. μητηρ, mother, and πολις, a city. The mother or chief city of a country or province: a metropolitan is the bishop of a mother church: as an adjective, metropolitan means belonging to a metropolis: metropolitical, chief or principal among towns or cities.

He fearing the power of the Christians was gone as far as Gratia, the *metropolitical* city of Stiria.
Knolles.

Their patriarch, of a covetous desire to enrich himself, had forborn to institute *metropolitan* bishops.
Raleigh.

He was promoted to Canterbury upon the death of Dr. Bancroft, that *metropolitan*, who understood the church excellently, and countenanced men of the greatest parts in learning. *Clarendon.*

His eye discovers unaware
The goodly prospect of some foreign land,
First seen: or some renowned *metropolis*,
With glistering spires and pinnacles adorned.
Milton.

We stopped at Pavia, that was once the *metropolis* of a kingdom, but at present a poor town.
Addison on Italy.

METROPOLIS is also applied to archiepiscopal churches, and sometimes to the principal or mother church of a city. The Roman empire having been divided into thirteen dioceses and 120 provinces, each diocese and each province had its metropolis, where the proconsul resided. To this civil division the ecclesiastical was afterwards adapted, and the bishop of the capital city had the direction of affairs, and the pre-eminence over all the bishops of the province. His residence in the metropolis gave him the title of metropolitan. This erection of metropolitans is referred to the end of the third century, and was confirmed by the council of Nice.

METTLE, *n. s.* } As Dr. Johnson thinks
MET'TLED, *adj.* } corrupted from METAL: but
MET'TLESOME. } the Belg. *moedwell*, and Teut. *mutwill*, signify animation; spirit; courage; sprightliness: mettled and mettlesome are, brisk; fiery; gay.

What a blunt fellow is this grown to be:
He was quick *mettle* when he went to school.
Shakspeare.

Oh thou! whose self-same *mettle*,
Whereof thy proud child, arrogant man is puft,
Engenders the black toad, and adder blue. *Id.*

Upon this heaviness of the king's forces, interpreted to be fear and want of *mettle*, divers resorted to the seditious. *Hayward's Edward VI.*

Such a light and *mettled* dance
Saw you never. *Ben Jonson*

He had given so frequent testimony of signal courage in several actions, that his *mettle* was never suspected. *Clarendon.*

Their force differs from true spirit, as much as a vicious from a *mettlesome* horse. *Tatler.*

Nor would you find it easy to compose
The *mettled* steeds, when from their nostrils flows,
The scorching fire that in their entrails glows.
Addison.

'Tis more to guide than spur the muse's steed,
Restrain his fury than provoke his speed;
The winged courser, like a generous horse,
Shows most true *mettle* when you check his course.
Pope.

But little wist she Maggie's *mettle*—
Ae spring brought off her master hale,
But left behind her ain grey tail:
The carlin claught her by the rump,
And left poor Maggie scarce a stump. *Burns.*

METTRIE (Julian Offray de la), M.D., a French physician, born at St. Maloes in 1709. He wrote the Natural History of the Soul, in which he denied its immateriality; and also a work against the physicians, for which he was compelled to leave France. He then retired to Leyden, where he wrote an atheistical work entitled L'Homme Machine, which was publicly burnt. He next went to Berlin, and was patronised by Frederick the Great. He died in 1751. His works were published in Berlin in 1 vol. 4to.

METZ, MEDIOMATRICES, DIVODURUM, or SOCIA CIVITAS, an ancient, large, and strong city in France, the chief place of the department of the Moselle, a post-town, and the seat of a bishop, containing 42,000 inhabitants. It is the principal military station of the third division, and has a royal court for the departments of the Moselle and the Ardennes; an inferior court; a chamber of commerce; and an exchange. Here is a royal school of artillery; also a university academy; societies of literature, arts, and sciences, and for the encouragement of agriculture and industry; a royal college; schools for drawing and painting, and mutual instruction in music; and public lectures in midwifery and botany.

This city is finely situated in a magnificent basin, at the confluence of the rivers Moselle and Seille. It is generally well built, and adorned with several excellent public edifices, particularly the governor's palace, the town-hall, court-house, military hospital, arsenals, college, assembly-room, a superb building, with a portico of the Tuscan order; and the cathedral, remarkable for the boldness, and yet astonishing lightness, of its architecture. The streets are broad, straight, and well paved, and next to Strasburg it is the best fortified place in France: there are seven gates, furnished with drawbridges; some of these

gates are double, treble, and even fourfold. The citadel, on the right bank of the Moselle, is capacious and very strong; and the ancient fortifications have been replaced by immense works constructed according to the modern system of defence, under the direction of marshals Vauban and Belleisle.

Metz was founded by the Gauls at a very early period, and was the capital of the Mediomatrices, a powerful nation of Belgic Gaul. It was a considerable place in the time of the Romans, who adorned it with several fine monuments. In 452 it was laid waste by Attila; afterwards the Franks invaded it, and it became the metropolis of the kingdom of Austrasia; it was successively subject to the emperors of Germany and the kings of France, till the eleventh century, when it became independent, under the protection of the empire, and enjoyed the privileges of a free city until the year 1552, when it again fell into the power of France, after Charles V. had besieged it with an army of 100,000 men, and been compelled to retire, having for sixty-five days assaulted it. It is the native place of Fabert, the illustrious warrior; of Adam Philippe Custine, commander-in-chief of the army of the north, executed at Paris on the 17th of August, 1793; of his son François Custine, who also suffered on the 7th of January, 1794; of Lacretelle the elder, distinguished for his learning; of the brothers Lallemand; and general Lasalle, who was slain at the battle of Wagram.

Manufactures are carried on here of coarse cloths, flannels, woollen stuffs, gold and silver lace, hats, embroidery, walking-sticks, paper-hangings, glue, &c. There are also cotton-spinning factories, numerous brass-foundries, starch, nail, and tile manufactories, and considerable tan-yards. The inhabitants trade in brandy, excellent beer, confectionary, drugs, spices, leather, iron and ironmongery, furniture, and timber of various sorts. Among the public places may also be mentioned the library, the cabinet of natural history, the botanical garden, the square of Croislin, and the esplanade, a very delightful walk. About five miles from the city, near the village of Jouy-aux Arches, are the remains of an aqueduct, which formerly served to conduct the waters of the Gorze to a naumachia toward the southern extremity of the town; seventeen arches are still standing, seven of which are entire. Metz is in long. 3° 51′ E., and lat. 49° 7′. Thirty-six miles south of Luxemburg, 123 north-west of Strasburg, and 237 east of Paris.

METZU (Gabriel), an eminent painter, born in Leyden in 1615. His subjects were usually taken from low life, and were all designed after nature, such as women selling fish, fowls, or hares; sick persons attended by the doctor; chemists in their laboratories; dead game, painters' shops, and drawing schools hung with pictures, &c. He died in 1658.

MEVANIA, in ancient geography, a town of the Cisappenine Umbria; seated at the confluence of the Tina and Clitumnus, on the Via Flaminia; famous for its herds of white cattle, brought up there for sacrifice. Mevania was the country of Propertius.

MEULEN (Anthony Francis Vander), a celebrated painter of battles, &c., born at Brussels in 1634. Some of his compositions, happening to be carried to Paris, were shown to M. Colbert, who soon discerned his abilities, and by his generous offers induced him to settle in Paris. Here he was employed by Louis XIV., and had a pension of 2000 livres beside payment for his work. He attended the monarch in most of his expeditions in the field, and designed on the spot the sieges, attacks, encampments, and marches of the king's armies; and from those sketches he composed the paintings which were intended to perpetuate the remembrance of those military exploits. He died in 1690. His chief works are at Versailles and Marli; but many of his easel pictures are dispersed through England, France, and Flanders.

MEURTHE, a department of France, consists of the southern part of the former province of Lorraine, and takes its name from the river Meurthe, which flows through it from south to north. The principal place of this prefecture is Nancy; it is divided into five arrondissements or subprefectures, Nancy containing 114,678 inhabitants; Chateau Salins 64,215; Luneville 73,817; Sarrebourg 64,780; and Toul 62,485; being a total population of 379,975 souls, on a superficial extent of 2790 square miles. These are subdivided into twenty-nine cantons, and 718 communes, yielding a revenue of 17,500,000 francs. It is in the third military division, having a royal court and a bishopric at Nancy, and is divided into three electoral arrondissements, which send five members to the chamber of deputies. This department is bounded by that of the Moselle on the north, on the east by that of the Lower Rhine, on the south by that of the Vosges, and on the west by that of the Meuse.

The face of the country is remarkable for the beauty of its scenery, and the variety of its productions; it is covered with mountains and hills, intersected by fine and fruitful plains, that are watered by the Moselle, the Sarre, the Meurthe. the Seille, the Verouze, the Madon, and the Mortagne, of which the Moselle and the Meurthe only are navigable here. Some of the hills are covered with vines, which produce good wine, the tops of the mountains are crowned with forests, and abound in excellent pastures. The soil of the plains, especially in the valley of the Meurthe and the Seille, is fertile in grain, of which a great quantity is exported. Hemp and flax also are successfully cultivated here, as well as wall-fruit trees, especially the apricot of Nancy. The meadows are rich and extensive, but the breed of horses and black cattle is small; the inhabitants are supplied with great quantities of fish from the rivers and ponds scattered over the country, and the forests abound in game of all sorts. There are likewise some mineral springs, and salt springs, that are very productive, and a stratum of rock salt, of an immense extent, of which the produce is incalculable. This country, which is rather stony, is cultivated by horses, and affords more than sufficient for its inhabitants; there are 218,980 hectars of forest land, chiefly oak and beech, and 13,500 hectars

of vineyards, the average produce of the hectar of arable land being 24 francs 12 centimes.

Besides the above productions, we may mention potatoes, beet-root, hops, rapeseed, plants of all sorts, excellent butter, horned cattle, merino and other sheep, goats, pigs, asses, mules, geese, bees, &c. There are also fine quarries of marble, freestone, graystone, grindstones, lithographic stones, earth for glass furnaces, and potter's clay. At Nancy there is a botanical garden, and a stud for horses at Bouxières. The inhabitants carry on manufactures of common cloths, hempen and cotton linen, embroidery of all kinds, playing-cards, paper-hangings, looking-glasses, crystals, pipes, liqueurs, mineral acids, candles, oil, basket-work, and turnery. They have also cotton-spinning factories, refining-houses for beet-root sugar, forges, bell-foundries, glass-houses, dye-houses, paper-mills, tan-yards, and potteries. Royal salt-works are established at Dieuze, Moyenvie, and Chateau Salins. In all the above articles a considerable trade is maintained with the whole country round.

This department is crossed by the great roads of Strasburg, Metz, Verdun, Bar-le-duc, Langres, Epinal, and Colmar.

Meurthe, the, a river in France, which, rising in the Vosges Mountains, at the back of Mount Bonhomme, divides itself into two streams, that descend the mountains of Valtin and Montaben, and unite below the bridge of Sandrouville, six miles to the south of St. Dié. It passes by Plainfaing, Faize, St. Marguerite, St. Dié, Raon-l'Etape, Baccarat, Luneville, Rosières, Dombasle, St. Nicolas, and Nancy, and falls into the Moselle below Frouard. This river flows at first with rapidity over a channel of gravel and flint, but it afterwards becomes more slow in its course, especially in the department to which it gives its name. It runs about 108 miles, receiving on its way the Verouze, the Mortagne, the Sanon, and several other small streams. It begins to be passable by rafts at Plainfong, in the department of the Vosges, and becomes navigable a little above Nancy. Along this river are conveyed chiefly fir timber in planks, which are sent down to Holland in floats of from 2000 to 3000 each, and fir wood.

MEURSIUS (John), a learned and laborious writer, born at Losdun, near the Hague, in 1579. He early discovered a fondness for the sciences; and at the age of sixteen he wrote a commentary on Lycophron. In 1610 he was made professor of history at Leyden; and afterwards Greek professor. In 1611 the magistrates of the United Provinces appointed him to write the history of his country. During fourteen years residence at Leyden he published more works than the whole body of professors had done from the foundation of the university in 1575. Christian IV. king of Denmark, in 1625, conferred on him the places of historiographer royal and professor of history and politics in the academy of Sora, where he resided twelve years. In 1638 he had a violent attack of the stone, from which he recovered, but died of a consumption induced by it on the 20th of September, 1639. He left behind him a son and a daughter. He was the author of many excellent historical, critical, and miscellaneous works; but the Meursii Elegantiæ Latinæ Sermonis, a scandalous indecent piece published in his name, was the production of one Westrenius, an advocate of Copenhagen.

MEUSE, a department of France, formed out of part of the former province of Lorraine, and taking its name from the river Meuse, which crosses it from south to north. The chief place of this prefecture is Bar-le-duc; it is divided into four arrondissements, Bar-le-duc, containing 76,889 inhabitants; Commercy 78,577; Verdun 74,426; and Montmedy 62,493; being a total population of 292,385 souls, on a surface of 2862 square miles. It consists of twenty-eight cantons, and 591 communes, yielding a revenue of 14,281,000 francs; and is part of the second military division, and of the diocese of Nancy, where there is also a royal court. It is further divided into two electoral arrondissements, which send four members to the chamber of deputies. This department is bounded on the north and north-west by that of the Ardennes, on the east by those of the Moselle and the Meurthe, on the south-east by that of the Vosges, on the south-west by that of the Upper Marne, and on the west by that of the Marne.

The face of the country is intersected with mountains, valleys, and plains; the mountains are lofty, covered with extensive forests, and abounding in game of all kinds; on the less elevated hills the vine is cultivated with success, and produces excellent wine, especially in the neighbourhood of Bar. The soil in the plains is in general poor and rather barren; but the valleys are exceedingly fruitful, yielding vast quantities of grain, rapeseed, flax, hemp, vegetables, and every sort of fruit. The Meuse is bordered with fine meadows and pastures, that feed a great number of cattle, in which the inhabitants carry on an extensive commerce. The ground, which is rather rocky, is cultivated with horses and oxen, and affords an ample supply for its inhabitants. There are 180,000 hectars of forests (oak, hornbeam, and beech), and 15,000 of vineyards, each hectare of cultivated land producing about 22 francs.

Besides what has been mentioned, this country produces fine red and white gooseberries, and fish of different sorts, especially trout and crabs. It has also numerous mines abounding in iron, and quarries of freestone, potters' clay, marl, and curious fossils. There are manufactures of cotton balls, cloths, and caps; casks, small shot, liqueurs, oils, and Gruyère cheese; cotton-spinning factories, forges, glass-houses, paper-mills, potteries, brass-foundries, tan-yards, and dye-houses, famous for the Adrianople red. In all the productions of these manufactories, as well as those of the soil, the inhabitants carry on a good trade.

The principal rivers that water this department are the Meuse, navigable; the Aire, the Ornain, the Chiers, the Ortain, the Saux, the Teinte, and the Orme. It is crossed by the great roads of Chalons-sur-Marne, Nancy, and Chaumont.

Meuse, the, a considerable river in France, which rises just above the village of Meuse, in the department of the Upper Marne. It is navigable from Verdun, in the department of the Meuse, as far as the frontiers of the kingdom, for an extent of about 150 miles, and from that place

to its mouth, a further extent of nearly 200 miles. The Meuse, after passing by Bourmont, suddenly disappears at the village of Bargaille, about three miles from Neufchateau; it afterwards flows by Domremy, Vaucouleurs, Commercy, St. Michael, Verdun, Dun, Stenay, Mouzon, Sedan, Mezieres, Charleville, Monthermé, Revin, Fumay, and Givet; below this last town it enters the kingdom of the Low Countries, near Dinant, passes by Namur, Liége, Maestricht, Ruremonde, Vanlo, and Ravenstein; eighteen miles below this town it unites in two places with that arm of the Rhine which bears the name of the Waal, and is called for some distance the Merwe; at Dordrecht it separates into two streams, one of which resumes the name of the Meuse, and the other, retaining that of the Merwe, passes on to Rotterdam; these two branches unite again at some distance, opposite to Wardingen, and under the name of the Meuse fall into the North Sea, between the Breille and Gravesend. The whole course of this fine river is about 480 miles, receiving, in its progress to its mouth, the Chiers, the Semoy, the Lesse, the Sambre, the Ourth, the Boër, and many other streams.

MEW, *n. s.* & *v. a.* Fr. *mue;* barb. Lat. *muta*; Ital. *muta*. A bird-cage or coop; 'properly,' says Mr. Thomson, 'a receptacle for hawks changing their feathers, and a place for changing carriages, horses, and whatever belonged to the chaise.' Hence, therefore, our use of the term 'mews.' To confine or shut up; to shed the feathers or any outward attire or distinction, as the hawk and other birds.

Mewing, the falling off or change of hair, feathers, skin, horns, or other parts of animals, which happens in some annually, in others only at certain stages of their lives: but the generality of beasts mew in the spring. An old hart casts his horns sooner than a young one, which is commonly in February and March, after which they begin to button in March or April: and as the sun grows strong, and the season of the year advances, their heads grow, and are summed full by the middle of June.

MEXICO. The Republic of the United States of Mexico, in central America, comprise the former Vice-royalty of Spain, and is bounded on the north by the United States of America and the Gulf of Mexico; on the east by the United States, Gulf of Mexico, and Bay of Honduras; on the south by Guatimala; and on the west by the Pacific Ocean; it is situated between lat. 15° and 42° N. and between long. 87° and 124° E. It extends 1850 miles in length, by about 1000 in breadth and contains an area of 1,690,000 square miles. The population exceeds 7,000,000 of inhabitants. Its geographical features are peculiar: embracing every species of soil, from the most recent alluvial to mountain valleys, or rather plateaus, elevated nearly 8000 feet above the sea. These plains are again broken by colossal masses, rising from twelve to seventeen thousand feet. From the difference of elevation, and from the extensive range which it embraces within the tropics, Mexico may be considered to possess every climate of the earth, and to be capable of producing every species of vegetable necessary to the wants or sought by the luxuries of human life; and from the great internal capability of production it follows, that few parts of the globe are better calculated to compose one independent political community. The mineral treasures of this country are perhaps its most important. They are placed within the valleys of the great mountain chains; and the richest mines of Mexico, those of Real del Monte, Guanaxuato, Tasco, and Zacatecas, are situated at an elevation of from five to six thousand feet above the sea. Gold is found in little straw-like fragments, and native silver in great abundance. Some of these mines have been worked to extraordinary depths: one in particular is excavated to the depth of 1640 feet, and its galleries extend a length of eight miles. The agricultural produce is of the most luxuriant kind, and raised with little labour. Wheat, rye, and barley are extensively cultivated, besides, two and three crops of each are taken annually. Logwood and mahogany are cut in the districts of Campeachy and Honduras, and cocoa and cochineal form articles of export, and here also grow the trees yielding the balsam of capaiva and tolu. Mexico possesses but few good harbours; Vera Cruz and Tampico, on the Gulf of Mexico, are the most frequented on the east shore, and Acapulco and San Blas on the west. The territorial sub-division of the Republic includes 18 intendancies and 3 territories. The former are named Mexico, Puebla, Guanazuato, Jalisco, Oajaca, Yucatan, Zacatecas, Michoachan, Durango, Vera Cruz, San Luis Potosi, Chihuahua, Queretaro, Chiapas, Tabasco, Tamaulipas, Nuevo Leon, Coahuila, Sonora, and Sinaloa. The territories are those of New Mexico, Alta California, and Baja California. The little territories or districts of Tlaxcala and Colima, consist of those cities respectively, with a small extent of contiguous country. In 1519, Cortez and his Spanish followers discovered Mexico, and founded Vera Cruz. The country was then governed by Montezuma; after his death, in 1520, Mexico was seized by the Spaniards, and Cortez became Captain-General of New Spain (Mexico) until 1535, when he was displaced by a Viceroy. The country may be said to have groaned under Spanish misgovernment, or to have lain exhausted, for three centuries: after which it at length arose from its lethargic and fallen state, and in 1821 declared itself totally independent of Spain, and formed its numerous provinces into the federal republic of Mexico. The capital of the new republic is the city of Mexico.

Mexico, a city of North America, the capital of the country of this name, is the oldest city of the New World of which we have any account. The original town, called by the natives Tenochtitlan, was founded in 1325 in the valley of Mexico on a group of islands in the lake Tezcuco. Three principal causeways of stone and earth connected it with the mainland. They were thirty feet wide, we are told, and of great length; the western one, or that of Tacuba, being a mile and a half; that of Tapeaca, on the north-west, three miles; and that of Cuoyacan, towards the south, six miles long. The bases of them

[illegible], and form, with some modern additions, [illegible] paved ways across the marshy grounds, [illegible] the city from being overflowed by the neighbouring lakes. The old city is said by Cortez, in a letter to Charles V., to be as large as Seville or Cordova. 'The streets, I merely speak of the principal ones,' he writes, 'are very narrow and long; some are half dry and half occupied by navigable canals, furnished with very well constructed wooden bridges, broad enough for ten men on horseback to pass at the same time. The market-place, twice as large as that of Seville, is surrounded with an immense portico, under which are exposed for sale all sorts of merchandise, eatables, ornaments made of gold, silver, lead, pewter, precious stones, bones, shells, and feathers; delft ware, leather, and spun cotton. We find hewn stone, tiles, and timber, fit for building. There are lanes for game, others for roots and garden fruits: there are houses where barbers shave the head with razors made of obsidian; and there are houses, resembling our apothecaries shops, where prepared medicines, unguents, and plasters, are sold. There are houses where drink is sold. The market abounds with so many things that I am unable to name them all to your highness. To avoid confusion, every species of merchandise is sold in a separate lane; every thing is sold by the yard, but nothing has hitherto been seen to be weighed in the market. In the midst of the great square is a house, which I shall call l'audiencia, in which ten or twelve persons sit constantly, for determining any disputes which may arise respecting the sale of goods. There are other persons who mix continually with the crowd, to see that a just price is asked. We have seen them break the false measures which they had seized from the merchants.'

This city was taken by Cortez, as we have seen, in the year 1521, after a siege of seventy-five days. The Spaniards were so irritated at this protracted resistance that they resolved to raze it to the ground, and, especially as the destruction of the streets on the exterior facilitated their approaches to the other and main parts of the town. The ancient Tenochtitlan was thus completely levelled, and the present city has risen from the ruins, although, from the diminution of the waters of the lake Tezcuco, it is situated about a league distant from its shore.

The valley in which it stands is nearly in the middle of the Cordillera of Anahuac, on the ridge of mountains which runs to the N.N.W. It is surrounded with an oval barrier of mountains, which inclose it like a wall, and is eighteen leagues and one-third in length, and twelve and a half in breadth. Baron Humboldt ascertained it by barometrical survey, to be raised to the height of 7200 feet above the level of the sea. At this elevation the city, notwithstanding its tropical position, enjoys a temperate climate, and even a considerable degree of cold is felt, from winds which at certain seasons burst from the north; the thermometer having been known at these times to fall below the freezing point. But this is rare; the winters are usually as mild as at Naples. In the cold season the mean heat is from 55° to 70° of Fahrenheit's thermometer: the thermometer in summer never rises above 75°. The whole neighbourhood, except on the east side, which is in fact the old bed of the lake and is impregnated with saline particles, is laid out in estates in the highest cultivation; orchards and gardens pour in a continual supply of fruits, flowers, and vegetables of all kinds, for the use of the inhabitants: the plan of the city is a square, extending from north to south, and from east to west, about four English miles. The streets are drawn at right lines, and are very spacious: the ground on which it stands quite level. It is surrounded with a wall of uncemented stone; and various small canals disperse the waters of the lake through some beautiful streets. In a great central square is the viceroy's palace: and there are different markets, where there is a regular supply of all the necessaries and luxuries of the climate. The chief public buildings whose magnificent architecture attracts attention are, 1. The cathedral, partly in the Gothic stile: the body of the edifice having two towers ornamented with pilasters and statues of very beautiful symmetry. 2. The treasury, adjoining the state palace. 3. The great convent of St. Francis, which from alms alone once possessed a revenue of £20,000 sterling. 4. The two united hospitals, of which the one maintains 600, and the other 800 children and old people. This noble establishment has a revenue of £10,000 a-year. 5. The accordada, or prison, in which the apartments are generally spacious, and in which they reckon that more than 1000 individuals are often confined. 6. The school of mines; and the whole provisory establishment, with its collections in physics, mechanics, and mineralogy. 7. The university and its public library. 8. The academy of fine arts, with a collection of ancient casts. 9. The sepulchral monument consecrated to Cortez, in a chapel of the Hospitale de los Naturales. 10. The mint of Mexico, said to be the largest and richest in the world. It is a building of very simple architecture, belonging to the palace; but its interior arrangements are very superior. It was begun in the year 1535; the coinage being at first carried on by individuals to whom the government farmed it; but since 1733 all the works have been placed under the direction of government officers. The number of workmen employed has often amounted to 400; and it is possible to coin here with ease pieces to the amount of £30,000,000 annually.

The chief manufactures carried on in Mexico are the printing of calicoes, manufactures of cloth, hard soap, and tobacco, which last was long a royal monopoly: the working of gold and silver, in its various branches, is also carried to great perfection. Wrought plate, vases, and church ornaments, were annually executed before the revolution to a great amount; and great taste was displayed in the execution of them.

Mexico is favorably situated for carrying on commerce both with Europe and Asia. Equally distant (i. e. about sixty-nine leagues) from the port of Vera Cruz on the east coast of America, and from Acapulco, the port on the western shore it is a central point between these two great continents, and well adapted for becoming a great depôt of their produce. At present the difficul-

ties of the roads, and the unsettled state of the governments around, alike present great obstacles to free internal intercourse.

According to the latest data, the population of this city, including military, appears to be from 135,000 to 140,000 souls, in something like the following proportion:

Europeans	2,500
White Creoles	65,000
Indigenous copper colored . .	33,000
Mestizoes, mixture of whites and Indians	56,000
Mulattoes	10,000
Total	166,500

The clergy, until very lately at least, formed a numerous and powerful body, amounting, including all descriptions, to 2392. The archbishop possessed revenues equal to £18,000 per annum.

MEXITLI, a god of war among the ancient Mexicans. The worship of this idol was most horribly bloody. Numberless human sacrifices were offered up at his shrine. Clavigero and bishop Zumarraga say, that 20,000 persons were annually sacrificed to this idol in Mexico alone. Gomara makes the number 50,000. The breasts of the victim were cut open alive, and their hearts torn out and sacrificed.

MEYER (Felix), an eminent landscape painter, born at Winterthur in 1653, and taught by a painter at Nuremburg. He was afterwards a disciple of Ermels, whose style he followed. In search of still greater improvement, however, he travelled to Italy; but, the climate not agreeing with his constitution, he retired to Switzerland, where, as he was indefatigable in surveying all the beauty, the wildness, and the magnificence of nature in those romantic scenes, he made a multitude of noble designs, which procured him very high reputation. But he was not expert at painting figures. Such of his landscapes as were supplied with figures by Roos, or Rugendas, are most esteemed. He died in 1713.

MEYER (James), a Flemish historian, born in 1491 near Ballieul, whence he is also named Baliolianus. He was rector of Blankenberg, and wrote, 1. Annales Rerum Flandricarum, fol. 2. Flandricarum Rerum Decas, 4to. He died in 1552.

MEYNT, or MEINT, *part. adj.* From Sax. menᵹe, to mingle. Mingled. Obsolete.

For even of love the sicknesse,
Is *meint* with swete and bitternesse. *Chaucer.*

The salt Medway, that trickling streams
Adown the dales of Kent,
Till with the elder brother Thames
His brackish waves be *meynt*.
Spenser's Pastorals.

MEYWAR, an extensive district of Hindostan, in the province of Ajmeer, situated between 25° and 26° of N. lat. It is possessed by a number of Rajpoot chiefs, dependent on the rajah of Odeypore, and is in general hilly, but produces sugar, tobacco, cotton, and grain; horses, camels, and cattle. Its principal manufactures are swords, matchlock musquets, and cotton cloths. The chief towns Odeypore, Shahpoorah, and Bilarah; its largest river is the Banasa.

MEYWAT, a district of Hindostan, in the province of Delhi, is situated between 27° and 29° of N. lat.; and, although within twenty-five miles of the capital of India, its inhabitants have always been described as singularly savage and brutal; so that the epithet of Meywatty has become synonymous with that of robber. This district has changed masters often enough perhaps to account for this: it is now nominally possessed by the Machery rajah, whose capital is the town of Alvar.

MEZANDERAN, a province of Persia, bounded east by Chorasan, south by Chusistan, Irak, west by Chilan, and north by the Caspian Sea. The south part is mountainous but very healthful; the north is so extremely fertile that it is styled the garden of Persia. Silk is the chief manufacture. Ferbad is the capital.

MEZENTIUS, in fabulous history, a king of the Tyrrhenians, infamous for his cruelties. Among other barbarities he tied the living and the dead together. Being expelled by his subjects he fled to Turnus, and fought under him against Æneas, by whom he was killed, with his son Lausus.—*Virg. Æn.* vii. 648, &c.

MEZERAI, or MEZERAY (Francis Eudes de), an eminent French historian, the son of Isaac Eudes, a surgeon, born at Rye, in Lower Normandy, in 1610; and who took the surname of Mezeray, from a hamlet near Rye. Having studied at Caen, he discovered a strong inclination for poetry; but going to Paris he applied himself to politics and history, and procured the place of commissary at war, which he held for two campaigns. He then shut himself up in the college of St. Barbe, in the midst of books and MSS., and, in 1643, published the first volume of the History of France, in folio; and, some years after, the second and third. He surpassed all who had written the History of France before him, and was rewarded by the king with a pension of 4000 livres. In 1668 he published an Abridgment of his History of France, in 3 vols. 4to, which was well received by the public; but as he inserted in that work the origin of most of the taxes, with very free reflections, M. Colbert complained of it, when Mezeray promised to correct what he had done in a second edition; but, those corrections being only palliations, the minister caused half of his pension to be suppressed. Mezeray complained of this in very severe terms; when he obtained no other answer than the suppression of the other half. Vexed at this treatment, he resolved to write on subjects that could not expose him to such disappointments; and composed his treatise on the Origin of the French. He was elected perpetual secretary to the French academy; and died in 1683. He is said to have been so careless in his dress that he often passed for a beggar, and was one morning actually seized by the parish officers; which was so far from provoking him that he was highly diverted with it, and told them that 'he was not able to walk on foot, but that, as soon as a new wheel was put to his chariot, he would attend them wherever they thought proper.' With regard to religion he affected Pyrr-

honism; which, however, was not so much in his heart as in his mouth. This appeared from his last sickness; for having sent for those friends who had been the most usual hearers of his licentious conversation about religion, he desired them 'to forget what he might formerly have said upon the subject of religion, and to remember that Mezeray dying was a better believer than Mezeray in health.' He also wrote, 1. A Continuation of the History of the Turks. 2. A French translation of John de Sarisbury's Latin treatise on the vanities of the court. 3. Several satires against the government, under the name of Sandricourt.

MEZE'REON, *n. s.* Arab. *mezereon.* Daphne or spurge laurel.

Mezereon is common in our gardens, and on the Alps and Pyrenean mountains: every part of this shrub is acrid and pungent, and inflames the mouth and throat. *Hill.*

Mezereon too,
Though leafless, well attired, and thick beset
With blushing wreaths, investing every spray.
Cowper.

MEZEREON. See DAPHNE.

MEZIERES, a small but strong town, the principal place of the department of the Ardennes, in France, possessing societies of agriculture, arts and sciences and commerce. It is a post-town, and of the fourth division, with an inferior court at Charleville, and contains 3,600 inhabitants; it is situated at the foot of a hill on the right bank of the Meuse, which divides it from Charleville; it is surrounded with considerable fortifications, and defended by a citadel. It is very confined, and in general badly built. In the year 1521 it was besieged by the emperor Charles V. with a powerful army, and bravely defended by the chevalier Bayard. In has, indeed, never been taken. Here are some famous tan yards, brass foundries, and edge-tool manufactories; and a trade is carried on in leather, serges, hats, linen, &c. The public library contains 4000 volumes. This town is fifteen miles W. N. W. from Sedan, sixty north-east from Rheims, and 177 north-east from Paris; in east long. from that city 2° 23', and N. lat. 49° 51'.

MEZIRIAC (Claude Gasper Backet sieur de), an ingenious author of the seventeenth century, was born at Bresse of an ancient and noble family. He was an excellent grammarian, a Greek scholar, and an admirable critic. He was deeply skilled in algebra and geometry, of which last he gave proof by publishing the six books of Diophantus, with a very able commentary and notes. In his youth he spent a considerable time in Paris and in Rome; at which last place he wrote a small collection of Italian poems, in competition with Vaugelas, who was there at the time; among which there are imitations of the most beautiful similies contained in the first eight books of the Æneid. He also translated Ovid's Epistles; a great part of which he illustrated with very curious notes. He began a translation of Plutarch's works, with notes; which he had nearly finished, when he died at Bourg in Bresse in 1638, aged forty-five. He left behind him several finished works in MS.

MEZUZOTH, in the Jewish customs, pieces of parchment which the Jews affixed to the door-posts of their houses, taking literally that precept of Moses, 'Thou shalt never forget the laws of thy God, but thou shalt write them upon the posts of thy house, and on thy gates.' But, in order to avoid the profanation of the wicked, they wrote these words upon a square piece of parchment prepared on purpose, with a particular ink, and a square kind of character: Deut. vi. 4, 5, 6, 7, 8, 9. 'Hear, O Israel, the Lord our God is one Lord,' &c. Then they left a space, and afterwards went on, Deut. xi. 13, 'And it shall come to pass, if thou shalt hearken diligently to my commandments,' &c. as far as, 'Thou shalt write them upon the door-posts of thy house,' &c. After this they rolled up the parchment, and put it into a case, on the end of which the word Shaddai, one of the names of God, was written; and they put it at the doors of their houses, chambers, &c. and fixed it to the knockers of the door, on the right side; and, as often as they entered in or went out, they touched it in this place with the end of their finger, which they afterwards kissed out of devotion. The Hebrew word mezuza properly signifies the door-posts of a house; but it is also given to this roll of parchment now mentioned. Leo of Modena may be consulted on this custom.

MEZZOTINTO is a particular manner of representing figures on copper, so as to form prints in imitation of painting in Indian ink. This invention has been attributed to prince Rupert. But baron Heinikin, a very judicious writer upon engraving, asserts, with great appearance of truth, that it was a lieutenant-colonel de Siegan, in the service of the landgrave of Hesse, who first engraved in this manner; and that the print which he produced was a portrait of the princess Amelia Elizabeth of Hesse, engraved in 1643. Prince Rupert learned the secret from this gentleman, and brought it into England, when he came over the second time with Charles II. Prince Rupert's print of an executioner holding a sword in one hand and a head in the other, a half length, from Spagnoletto, is dated 1658. This art has never been cultivated with success in any country but in England. The prince laid his grounds on the plate with a channelled roller; but one Sherwin, about the same time, laid his grounds with a half round file, which was pressed down with a heavy piece of lead. Both these grounding-tools have been laid aside for many years; and a hand-tool, resembling a shoemaker's cutting board knife, with a fine crenelling on the edge, was introduced by one Edial, a smith by trade, who afterwards became a mezzotinto painter. It is very different from the common way of engraving. To perform it, they rake, hatch, or punch the surface of the plate all over with a knife, or instrument made for the purpose, first one way, then the other, across, &c., till the surface of the plate be thus entirely furrowed with lines or furrows, close, and, as it were, contiguous to each other; so that if an impression was then taken from it, it would be one uniform blot or smut. This done, the design is drawn or marked on the same face; after which, they proceed with burnishers, scrapers, &c., to expunge and

take out the dents or furrows, in all the parts where the lights of the piece are to be; and that more or less as the lights are to be stronger or fainter; leaving those parts black which are to represent the shadows or deepenings of the draught. As it is much easier to scrape or burnish away parts of a dark ground corresponding with the outline of any design sketched upon it, than to form shades upon a light ground by an infinite number of hatches, strokes, and points, which must all terminate with exactness on the outline, as well as differ in their force and manner; the method of scraping, as it is called in mezzotinto, consequently becomes much more easy and expeditious than any other method of engraving. The instruments used in this kind of engraving are cradles, scrapers, and burnishers. In this engraving, the plate must be prepared and polished in the same manner as for other engraving; and afterwards divided equally by lines parallel to each other, and traced out with very soft chalk. The distance of these lines should be about one-third of the length of the face of the cradle which is to be used; and these lines should be marked with capital letters, or strokes of the chalk. The cradle is then to be placed exactly between the first two lines, and passed forwards in the same direction; being kept as steady as possible, and pressed upon with a moderate force. The same operation must be repeated with respect to all the other lines; till the instrument has thus passed over the whole surface of the plate. Other lines must be then drawn from the extremities of the other two sides, in the same manner; which, intersecting the first at right angles, will with them form squares; and the same operation must be repeated with the cradle as in the case of the first. New lines must then be drawn diagonally, and the cradle passed betwixt them as before; and, when the first diagonal operation is performed, the lines must be crossed at right angles as the former, and the cradle passed betwixt them in the same manner. The plate having undergone the action of the cradle, according to the disposition of the first order of lines, a second set must be formed, having the same distances from each other as the first. But they must be so placed as to divide those already made into spaces one-third less than their whole extent; i. e. every one after the first on each side will take in one-third of that before it, e. g. beginning at A, of which the first third must be left out; a third of B will consequently be taken in, and so of the rest. These lines of the second order must be marked with small letters, or lesser strokes, to distinguish them from the first; and the same treatment of the plate must be pursued with respect to them as was practised for the others. When this second operation is finished, a third order of lines must be made; the first of which, e. g. in A, must omit two-thirds of it, and consequently take in two-thirds of B, &c. By these means the original spaces will be exactly divided into equal thirds; and the cradle must be again employed betwixt these lines as before. When the whole of this operation is finished it is called one turn; but, in order to produce a very dark and uniform ground, the plate must undergo the repetition o all these several operations for above twenty times; beginning to pass the cradle again betwixt the first lines, and proceeding in the same manner through all the rest. When the plate is prepared with a proper ground, the sketch must be chalked on it, by rubbing the paper on the back side with chalk. It is also proper to overtrace it afterwards with black-lead or Indian ink. The scraping is then performed, by paring or cutting away the grain of the ground in various degrees; so that none of it is left in the original state, except in the touches of the strongest shade. The general manner of proceeding is the same as drawing with white upon black paper. The masses of light are first begun with; and those parts which go off into light in their upper part, but are brown below: the reflections are then entered upon; after which the plate is blackened with a printer's blacking-ball made of felt, to discover the effect; and then the work is proceeded with, observing always to begin every part in the places where the strongest lights are to be. The art of scraping mezzotintoes has been applied to the printing with a variety of colors, in order to produce the resemblance of paintings. The inventor of this method was J C. Le Blon, a native of Frankfort, and pupil of Charles Marata, between 1720 and 1730. It was established by the inventor on this principle, that there are primitive colors, of which all the rest may be composed by mixing them in various proportions; that any two of these colors being mixed together, preserve their original power, and only produce a third color, such as their compound must necessarily give; but if transparent colors be mixed, and three primitive kinds be compounded together, they destroy each other, and produce black, or a tendency to it, in proportion to the inequality or quality of the mixture; and that if, therefore, three colors be laid, either separately or upon each other, by three plates, engraved correspondently on these principles to the coloring of the design, the whole variety of teints necessary may be produced. The requisites, therefore, to the execution of any design in this method of printing, are as follows:—1. To settle a plan of the coloring to be imitated; showing where the presence of each of the three simple colors is necessary, either in its pure state, or combined with some other, to produce the effect required; and to reduce this plan to a painted sketch of each, in which not only the proper outlines, but the degree of strength, should be expressed. 2. To engrave three plates according to this plan, which may print each of the colors exactly in the places where, and proportion in which, they are wanted. 3. To find three transparent substances proper for printing with these three primitive colors.

The manner in which M. Le Blon prepared the plates was as follows:—The three plates of copper were first well fitted with respect to size and figure to each other, and grounded in the same manner as those designed for mezzotinto prints; and the exact place and boundary of each of the three primitive colors, conformably to the design were sketched out on three papers.

answering in dimensions to the plate. These sketches were then chalked on the plates; and all the parts of each plate, that were not to convey the color to which it was appropriated to the print, were entirely scraped away, as in forming the light of mezzotinto prints. The parts that were to convey the colors were then worked upon; and, where the most light or diluted teints of the color were to be, the grain in the ground was proportionably taken off; but where the full color was required it was left entire. In this regard was had, not only to the effects of the color in its simple state, but to its combined operation, either in producing orange-color, green, or purple, by its admixture with one alone; and likewise to its forming brown, gray, and shades of different degrees, by its co-operation with both the others. But, though the greatest part of the engraving was performed in the mezzotinto manner, yet the graver was employed occasionally for strengthening the shades, and for correcting the outline, where it required great accuracy and steadiness. It was necessary sometimes to have two separate plates for printing the same color, in order to produce a stronger effect; but the second plate, which was used to print upon the first, was intended only to glaze and soften the colors in particular parts that might require it. As to the black and brown teints, which could not be so conveniently produced in a due degree by the mixture of the colors, umber and black were likewise used. As to the order in which the plates are to be applied, the color which is least apparent in the picture should be laid on first, that which is betwixt the most and least apparent next, and that which predominates last; except where there may be occasion for two plates for the same color, or where there is any required for adding browns and shades. M. Le Blon applied this art to portraits, and showed, by the specimens he produced, the possibility of its being brought, by farther improvements, to afford imitations of painting which might have some value. It is nevertheless much better adapted to the simpler subjects, where there are fewer intermixtures of colors; and where the accuracy of the reflections, and demi-teints, are not so essentially necessary to the truth of the design, from the greater latitude of the form and disposition of the color, as in plants, anatomical figures, and some subjects of architecture. But perhaps plates engraved, or rather finished with the tool, particularly with respect to the outline, would be better accommodated in some of these cases than those prepared only by scraping. Mr. Cochin remarks, at the end of an account given of M. Le Blon's manner, that, though this ingenious artist confined his method principally to the use of three colors; yet, should this invention be again taken up and cultivated, there would be more probability of success in using a greater variety; and that several different kinds might be printed by one plate, provided they were laid on in their proper places by printing-balls, which should be used for that color only. His hint might, however, be very greatly improved, by the further assistance of pencils, accommodated to the plates, for laying on the colors in the proper parts.

The art of mezzotinto engraving was at first considered as only adapted to broad subjects; and, where high minute finishing was required, it was thought vain to attempt it; but the great advance made since the introduction of the art has convinced every artist and amateur to the contrary; and the successful works of Eadom (especially his masterly flower-pieces) are admirable specimens of its power, as also are the beautiful productions of Hodges, Dixon, and many other artists of the present day. It is decidedly most appropriate for the engraving of portraits, both as to touch and effect. The art of scraping mezzotinto has been applied to the printing with a variety of colors, in order to produce the resemblance of paintings.

MEZZOVO, a considerable trading town of Albania, Greece. It is an inland place, and about twenty-two miles north by east of Joannina. Inhabitants (descendants of a colony of Bulgarians) about 7500.

MIAMI, a country of the United States, in the south-west part of Ohio, North America; watered by the Miami Rivers, including the countries of Champaign, Clinton, Clermont, Green, Hamilton, Warren, Butler, Preble Montgomery, Miami, and Dark.—It is the name also of three inconsiderable townships of the Ohio state.

MIAMI, a county of the United States, in Ohio. Troy is the chief town.

MIAMI BAY, a bay on the south-west shore of Lake Erie, in North America, at the mouth of the Miami of the Lakes. It is about eighteen miles in circumference. It affords good anchorage and shelter.

MIAMI, GREAT, a river of the United States, in Ohio, which has its rise in the Indian country, between lat. 40° and 41° N. from two branches. The united streams flow south and south-west, and enter the Ohio in lat. 39° 4′ N. twenty miles below Cincinnati. It interlocks with the head branches of the Wabash; and with those of the Miami of the Lakes and the Scioto. Its entire length is 130 miles: it is 200 yards wide at its mouth; and flows through a wide and fertile valley, liable to partial inundation. It is navigable for boats seventy-five miles.

MIAMI, LITTLE, has its source in Green county, in the state of Ohio, and falls into the river Ohio, six miles above Cincinnati. Its length in a direct line is not more than sixty miles, but twice that distance if its windings are taken into the account. It is 150 yards wide at its mouth during high water, and its course is nearly parallel with the Great Miami, being nowhere more than twenty miles distant. The channel is precipitous, affording an immense number of mill-seats. Several paper-mills are already established on its banks.

MIAMI OF THE LAKES, a river of the United States, which rises in Indiana, and is formed by the St. Joseph's and St. Mary's, and running E.N.E. through the north-west part of the Ohio state. It flows into Miami Bay, at the west end of Lake Erie. It is navigable to Fort Wayne 120 miles, interrupted only by the rapids above Fort Meigs, which are fifteen miles long, and commence eighteen miles from its mouth.

MI'ASM, *n. s.* } Gr. μιαινω, to daub, or in-
MIAS'MA, } fect. Impurity, real or supposed, in the air, such as to communicate infection or disease.

The plague is a malignant fever, caused through pestilential *miasms* insinuating into the humoral and consistent parts of the body.

Harvey on Consumptions.

The variety of effects induced by different impurities of the air renders it absolutely necessary to discriminate them with as much accuracy as possible. We shall, therefore, confine the term *miasma* to its original meaning, as used by Hippocrates, and, as all the rest have appropriate terms, we shall defer them to the articles in their order. *Dr. A. Rees.*

MIAVA, a town of Hungary on the Miava River, which joins the Morava. It contains 10,000 inhabitants, chiefly Lutherans, and some manufactures of woollen and linen, considerable distilleries. Population (of Sclavonian origin) 10,000. Forty-five miles N. N. E. of Presburg, and sixty-three north-east of Vienna.

MICAH, the seventh of the twelve minor prophets. He is cited by Jeremiah, and prophesied in the days of Jotham, Ahaz, and Hezekiah. He censures the reigning vices of Jerusalem and Samaria, and denounces the judgment of God against both kingdoms. He also foretels the confusion of the enemies of the Jews, the coming of the Messiah, and the glorious success of the church.

MICAH, or THE BOOK OF MICAH, a canonical book of the Old Testament, written by the prophet Micah.

MICAIAH, the son of Imlah, an Ephraimite, a faithful prophet of Israel, under Ahab, who predicted the death of that monarch. See 1 Kings, xxii. 8—28, and AHAB.

MICHAEL, or MICHEL, i. e. who is like to God? The scripture account of Michael is, that he was an archangel, who presided over the Jewish nation, as other angels did over the Gentile world, as is evident of the kingdoms of Persia and Greece (Dan. x. 13); that he had an army of angels under his command (Rev. xii. 7); that he fought with the dragon, or Satan, and his angels; and that, contending with the Devil, he disputed about the body of Moses (Jude 9). As to the combat between Michael and the Dragon, some authors understand it literally. Others take it in a figurative sense: and refer it either to the contest that happened at Rome between St. Peter and Simon Magus, in which the apostle prevailed over the magician, or to those violent persecutions under which the church labored for 300 years. The Romish church celebrates three appearances of Michael, which happened, they say, long after the age of the apostles: viz. 1. At Colossæ in Phrygia, but when is uncertain. 2. At Mount Garganus, in Naples, about the end of the fifth century. 3. His appearance to Aubert bishop of Avranches, A. D. 706, upon a rock called the Tomb, where the abbey of St. Michael stands. The first of these festivals is observed on the 6th of September, the second on the 8th of May, and the last on the 16th of October. It has been supposed that it was Michael who conducted the Israelites in their journey through the wilderness (see Exod. xxxii. 34. and xxxiii. 2); who appeared to Moses in the burning bush, to Joshua in the fields of Jericho, and to Gideon and Manoah the father of Sampson. In a word, to him have been imputed the greatest part of the most remarkable appearances in the Old and New Testament. Bishop Horsely, in his remarkable sermon on Dan. iv 17, labors to prove that Michael the archangel is the Redeemer.

MICHAEL, MOUNT, one of the most celebrated state prisons of France, lies about twenty miles from Granville. It is a rock situated in the middle of the bay of Avranches; and is only accessible at low water. One side is naturally completely fortified by its craggy and almost perpendicular descent, which renders it impracticable to climb it by any address or courage, however consummate. The other parts are surrounded by walls fenced with semilunar towers after the Gothic manner, but sufficiently strong, together with the advantage of its situation, to render it impregnable to any attack. At the foot of the mountain begins a street or town, which winds round its base to a considerable height. Above are chambers where state-prisoners were kept, and where there are other buildings intended for residence. On the summit is erected the abbey itself, occupying a prodigious space of ground; and of a strength and solidity equal to its enormous size; as it has for many centuries withstood all the injuries of the weather, to which it is so much exposed. In an apartment, called the Sale de Chevalerie, the knights of St. Michael used to meet in solemn convocation, on important occasions. They were the defenders and guardians of this mountain and abbey, as those of the temple, and of St. John of Jerusalem, were of the holy sepulchre.

MICHAEL (St.,) or ST. MICHAEL'S, a borough of Cornwall, between St. Columb and Truro, 247 miles from London. Though one of the oldest boroughs in the county by prescription, it is now a mean hamlet in the parishes of Newland and St. Enidore; yet it is governed by a portreeve, chosen annually by a jury of the chief inhabitants, out of the six chief tenants, called deputy lords of the manor, because they hold lands in the borough. It has two fairs, and a court-leet is held twice a-year. It was formerly called Modishole.

MICHAEL (St.), GULF OF, a bay of South America, on the south-east side of the Gulf of Panama, and formed by the mouths of the rivers Congo, Santa Maria, &c. It has several islands which form a very good shelter for a large fleet, and its sides are surrounded with mangroves.

MICHAELIS (John David), a celebrated biblical critic, and author of many esteemed works, was the eldest son of a professor in the university of Halle in Lower Saxony, and was born there, February 27th 1717 He received the first part of his education in a celebrated Prussian seminary, called the Orphan-house, at Glauche, near Halle. He commenced his academical career at Halle in 1733, and took his degrees of A. M. and of philosophy in 1739. In 1741 he came to England, where his knowledge of the oriental languages, which was increased by his indefatigable researches in the

Bodleian library at Oxford, introduced him to the acquaintance and esteem of our first literary characters; with several of whom, particularly bishop Lowth, he corresponded for many years. He returned to Halle in fifteen months, and began to read lectures on the historical books of the Old Testament, which he continued after his removal to Gottingen in 1754. In 1746 he was appointed professor extraordinary, and soon after of philosophy. In 1747 he was appointed secretary to the Royal Society there, of which he was director in 1761, and was soon after made Aulic counsellor by the court of Hanover. In 1764 a publication relative to a journey to Arabia, which was undertaken by several literary men, at the expense of the king of Denmark, procured him the honor of being chosen a member of the Academy of Inscriptions at Paris, of whom the institution admitted only eight; and in the same year he became a member of the society at Haerlem. In 1775 count Hopkin, who eighteen years before had prohibited the use of his writings at Upsal, when chancellor of that university, prevailed upon the king of Sweden to confer on him the order of the polar star, as a national compensation. In 1768 he was appointed a privy counsellor of justice by the court of Hanover; and in 1788 received his last literary honor, by being elected F. R. S. of London. His great critical knowledge of the Hebrew, which he displayed in a new translation of the Bible, and in other works, raised him to a degree of eminence almost unknown before in Germany; and his labors were indefatigable in instructing the numerous students of all countries who attended his admirable lectures, which he continued to deliver on the sacred writings in half yearly courses, and on the Hebrew, Arabic, and Syriac languages, to the last year of his life. He was professor in the university of Gottingen forty-five years, and died October 22d, 1791, aged seventy-four. He left behind him several valuable MSS.

MIC'HAELMAS, *n. s.* Michael and mass. The feast of the archangel Michael, celebrated on the 29th of September.

They compounded to furnish ten oxen after *Michaelmas* for thirty pounds price. *Carew.*

MICHAELOVKA, a town in the government of Kursk, European Russia, on the Svapa. It has manufactures of leather, hemp, seed, oil, and wax; and trades in wood, corn, and hemp. Population 6000. Sixty-two miles W. N. W. of Kursk.

MICHE, *v. n.* } Sax. mæcꞇan; Teut. *mau-*
MICH'ER, *n. s.* } *chen,* to conceal. To lie hid or neglected: mich and mick are still used provincially for an idle, or small (easily concealed) person: a micher is used below for a loiterer.

How tenderly, her tender hands between,
In ivory cage she did the *micher* bind. *Sidney.*

Marry this is *miching* malicho; it means mischief. *Shakspeare.*

Shall the blessed son of heaven prove a *micher*, and eat blackberries? a question not to be asked. Shall the son of England prove a thief, and take purses? a question to be asked. *Id.*

MICHIGAN LAKE, a lake of North America, belonging to the United States, is 262 miles in length, and fifty-five in breadth, containing, according to Hutchings, 10,368,000 acres. It has a depth of water sufficient for vessels of any size, and has a communication with Lake Huron, by the river or channel of Michillimackinack. The waters of this, as well as of the other great lakes, are clear and wholesome, and contain abundance of fish. Its banks are fertile, and in the north-west are two excellent bays, i. e. Noquet's and Green's.

MICHIGAN TERRITORY, a territory of the United States, is a large peninsula, bounded on the north by the straits of Michillimackinack; on the north-east by Lake Huron; on the east by St. Clair's River and Lake, by Detroit River, and Lake Erie; on the south by Ohio and Indiana; and on the west by Lake Michigan. Long. 82° 7′ to 85° 20′ W., lat. 41° 45′ to 45° 34′ N.; two hundred and fifty miles long, from north to south, and one hundred and fifty miles broad; and containing about thirty thousand square miles.

The territory is divided into 18 counties, 14 of which lie to the east, and 4 to the west of Lake Michigan. They are,

Berrien	Monroc	Wayne	
Cass	Oakland	Detroit, City	
Jackson	St. Clair	Brown	West
Lenamee	St. Joseph	Chippewa	of Lake
Macomb	Van Buren	Crawford	Michi-
Michillimackinac	Washtenaw	Towa	gan.

The chief towns are Detroit, Niles, Edwardsbury, and Mackinac, and the population of the territory amounts to 31,260 inhabitants, few of whom are in slavery.

The rivers of this territory are numerous, and mostly navigable for boats to their sources. Those flowing into Lake Michigan are St. Joseph's, Black, Marame, Barbice, Raisin, Grand, Mastigon, White, Rocky, Beauvais, St. Nicholas, Marguerite, Monistic, Aux Sables, and Grand Traverse. Saganaum River flows in Saganaum Bay in Lake Huron.

There are no mountains in this territory; the interior is table land, having a northern and western inclination, interspersed with small lakes and marshes, from which issue the head branches of the river. There are prairies, from the banks of St. Joseph's to Lake St. Clair; some of an excellent soil, others sandy, wet, and sterile. There are also extensive forests of lofty timber, consisting of oak, sugar maple, beach, ash, poplar, white and yellow pine, cucumber, buckeye, bass-wood, hickory, cedar, plum, crab apple, cherry, black and honey locust. The timbered lands are well adapted to the production of most kinds of grain. There is no part of the United States more abundantly supplied with fish, aquatic fowls, and wild game.

The climate generally is accounted healthy. In the southern part it resembles that of the west part of New York and Pennsylvania. In the northern part it is more severe.

MICHILLIMACKINACK, a broad river or strait, by which Lake Huron communicates with that of Michigan. It is six miles wide, and from twenty to thirty long.

MICHILLIMACKINACK, or MACKINACK, an island and fort, situated in the above straits. The island is of an elliptical form, full of wood, and about seven miles in circumference, rising towards the centre, its figure suggesting to the Aborigines the appropriate name of Michi Mackina, or Great Turtle. The fort stands on a rising ground, 150 feet above the waters of the lake, 100 from its shores. It is a strong stockade, neatly built, and exhibits a fine appearance from the water. A village near the fort contains a Roman Catholic church, and 100 or 150 small houses. It is considerably resorted to by all the north-west traders. The climate is severe. 200 miles N.N.W. of Detroit.

MIC'KLE, *adj.* Sax. micel; Goth. and Swed. *mickel;* Scot. *muckle.* Much; great. See MUCH.

This reade is rife that oftentime
Great cumbers fall unsoft:
In humble dales is footing fast,
The trode is not so tickle,
And, though one fall through heedless haste,
Yet is his miss not *mickle*. *Spenser's Pastorals.*

O, *mickle* is the powerful grace, that lies
In plants, herbs, stones, and their true qualities.
Shakspeare.

Many a little makes a *mickle*. *Camden's Remains.*

All this tract that fronts the falling sun,
A noble peer, of *mickle* trust and power,
Has in his charge. *Milton.*

MICKLE (William Julius), the celebrated translator of the Lusiad, was born about 1735, and was educated by his father. After the death of his father he came to Edinburgh to reside with an uncle who was a brewer there, and who admitted him into a share of his business; but disliking the trade he went to London about 1761, with a view to procure a commission in the marine service. The first of his poems which appeared in print was published in one of the Edinburgh magazines, and entitled On passing through the Parliament Close of Edinburgh at Midnight. In 1756 he published the poem which first brought him into notice, entitled Pollio, an Elegiac Ode, written in the wood near R—— (Roslin) Castle, 4to. This was an elegy on the death of his brother, which, previously to its publication, had been shown to lord Lyttleton, and received some corrections from him. The latter, in an epistle to the author, spoke of it as equal to any thing of the kind in our language. In 1767 he published a poem called The Concubine, in two Cantos, after the manner of Spenser, 4to.; and in 1769 a Letter to Mr. Harwood, wherein some of his evasive Glosses, false Translations, and blundering criticisms, in support of the Arian heresy, contained in his Literal Translation of the New Testament, are pointed out and confuted, 8vo. In 1770 he published Mary Queen of Scots, an elegy; Hengist and Mary, a ballad; and Knowledge, an ode; in Pearche's Collection of Poems: also Voltaire in the Shades, or Dialogues on the Deistical Controversy, 8vo. About this time Mr. Mickle was a frequent writer in the Whitehall Evening Post; but a more important work now engaged his attention. This was the translation of the Lusiad of Camoens into the English Language, and which he completed in 1775. A second edition was prepared in 1778, with a plate prefixed to it, executed by Mortimer; on whom Mr. Mickle wrote an epitaph in 1779. This year also he published a pamphlet, entitled A Candid Examination of the Reasons for depriving the East India Company of its Charter. Bishop Lowth would have provided for him in the church, but this was not agreeable to our author's disposition; and he was soon after appointed secretary to commodore Johnstone, who had obtained the command of the Romney man of war. In 1771 he arrrived at Lisbon, and was named by his patron joint agent for the prizes which were taken. In this capital he resided above six months, and during this period he wrote his poem, entitled Almada Hill, which in 1781 was published in 4to. In 1782 he published the Prophecy of Queen Emma, an ancient ballad lately discovered, written by Johannes Turgottus, prior of Durham, in the reign of William Rufus; to which is added by the Editor, an Account of the Discovery, and hints towards a vindication of the Authenticity of the Poems of Ossian and Rowley, 8vo. In June 1782 he married Miss Tomkins, daughter of Mr. Tomkins of Forest-hill. Having received some fortune with this lady, and having saved some money himself when in the service of commodore Johnstone, he now enjoyed a comfortable independence. Having fixed his residence at Wheatley, in Oxfordshire, the last seven years of his life were employed in writing for the European Magazine. The fragments of Leo, and some of the most approved reviews of books, in that work were of his production. He died on the 25th of October 1788 at Wheatley, leaving one son.

MI'CROCOSM, *n. s.* From Gr. μικρος, little, and κοσμος, world. The little world: a term often metaphorically applied to man.

You see this in the map of my *microcosm*.
Shakspeare.

She to whom this world must itself refer,
As suburbs, or the *microcosm* of her;
She, she is dead; she's dead, when thou knowest this,
Thou knowest how lame a creeple this world is.
Donne.

How doth the head of this *microcosm* resemble that round celestial globe. *Bp. Hall.*

As in this our *microcosm*, the heart,
Heat, spirit, motion, gives to every part.
So Rome's victorious influence did disperse
All her own virtues through the universe.
Denham.

Philosophers say that man is a *microcosm*, or little world, resembling in miniature every part of the great; and the body natural may be compared to the body politick. *Swift.*

MICROCOSMIC SALTS. A triple salt of soda, ammonia, and phosphoric acid, obtained from urine, and much used in assays by the blowpipe. This compound is best procured by mixing equal parts of the phosphate of soda and phosphate of ammonia in solution, and then crystallising. A faint excess of ammonia is useful in the solution.

MICROG'RAPHY, *n. s.*
MICROM'ETER,
MI'CROSCOPE
MICROSCOP'IC, *adj.*
MICROSCOP'ICAL.
} Of μικρος, little, and γραφω, to describe; μετρον, a measure, and σκοπεω, to inspect.

Micrography is the description of small, or microscopic, objects: micrometer, an instrument for measuring small spaces or distances, particularly in the heavens: microscope, an optical instrument for magnifying small, and otherwise invisible, bodies. See the scientific description of both these important instruments.

The honey bag is the stomach, which they always fill to satisfy and to spare, vomiting up the greater part of the honey to be kept against winter; a curious description and figure of the sting see in Mr. Hook's *micrography*. *Grew's Museum.*

If the eye were so acute as to rival the finest *microscopes*, and to discern the smallest hair upon the leg of a gnat, it would be a curse, and not a blessing to us; it would make all things appear rugged and deformed; the most finely polished crystal would be uneven and rough; the sight of our own selves would affright us; the smoothest skin would be beset all over with ragged scales and bristly hairs. *Bentley.*

Make *microscopical* observations of the figure and bulk of the constituent parts of all fluids.

Arbuthnot and Pope.

The critick eye, that *microscope* of wit,
Sees hairs and pores, examines bit by bit.

Dunciad.

Why has not man a *microscopic* eye?
For this plain reason, Man is not a fly:
Say what the use, were finer opticks given,
T' inspect a mite, not comprehend the heaven?

Pope.

Evading even the *microscopic* eye!
Full nature swarms with life.

Thomson's Summer.

MICROMETER. The telescope and microscope both owe their most important applications to the use of this instrument. To the modern introduction of the micrometer for the use of the astronomer, and the improvement of the telescope, may indeed be attributed our accurate and extensive acquaintance with the universe of matter; while, from the perfection to which the microscope has recently been brought, an equal acquaintance with the minute organisation of bodies may be expected. By the application of the micrometer to this latter instrument the power of the naturalist is materially extended; while the micrometer is of the utmost value for trigonometrical surveys, and in military or naval operations.

M. de la Hire, in a discourse on the era of the inventions of the micrometer, pendulum clock, and telescope, before the Royal Academy of Sciences, makes M. Huygens the inventor of this instrument. 'That author,' he observes in his observations on Saturn's ring, &c., published 1659, 'gives a method of finding the diameters of the planets by means of a telescope, viz. by putting an object which he calls a virgula, of a size proper to take in the distance to be measured, in the focus of the convex object-glass; in this case, says he, the smallest object will be seen very distinctly in that place of the glass. By such means, he adds, he measured the diameter of the planets, as he there delivers them.' 'This micrometer,' continues the same ingenious author, 'is so very little different from that published by the marquis de Malvasia, in his Ephemerides, three years after, that they ought to be esteemed the same; and the micrometer of the marquis differed yet less from that published four years after his, by Azout and Picard. Hence de la Hire concludes 'that it is to Huygens the world is indebted for the invention of the micrometer, without taking any notice of the claim of our countryman Gascoigne, which, however, is many years prior to any of them.'

We may now, however, proceed to a more minute examination of this instrument, commencing with its simplest form.

The *wire micrometer* is an instrument fitted to the eye-piece of a telescope, for the purpose of measuring the angles subtended by small spaces in the heavens, such as the diameters of the planets, &c., by comprehending these spaces between two delicate parallel fibres, which retain their parallelism while they are opened and shut by a mechanical contrivance. This instrument is represented in plate I. MICROMETER, figs. 1 and 2, as attached, along with the eye-piece G F, to the tube of the telescope A A, by means of a screw round the circumference of the circular plate *d*, figs. 1 and 2. Within this circular plate is fixed a conical ring *e e*, fig. 2, fastened to a second ring B B, by three small screws, the ends of which may be seen in fig. 2. By turning the screw D, therefore, which works in teeth cut upon the circumference *d*, the whole eye-piece, along with the micrometer M N, may be made to revolve upon the conical ring *e e* as a centre. The inclination of the micrometer to the horizon is pointed out upon the flat surface of the ring *d*, which is divided into 360°, &c. Into the ring B B is screwed the common Huygenian eye-piece F G. The micrometer itself is contained in the box E E, figs. 1 and 3, which moves freely through the square holes in the ring B B, that the observer may follow an object while it is passing quickly through the field of the telescope. To show the interior construction of the instrument we have represented it, in fig. 3, with one of the sides removed. The fork of brass *n n* is fixed to the largest of the two small screws on the right hand side of the figure, and on the other end of the screw is placed a nut, L, united to the divided head N, and moving, with its female screw, upon the male screw already mentioned. By turning the nut L the fork *n n* may be moved backwards and forwards in the directions N M, M N, without any lateral shake. Within the fork *n n* is placed a second fork *o o*, fixed to another male screw on the left hand side of the figure, which may in like manner be moved backwards and forwards by means of the nut M, fixed to the divided head P. Across the lower side of each fork is extended a delicate fibre, or silver-wire, *e e*, which partakes of the motion of the fork to which it belongs, and both these fibres are so fixed that they always continue parallel, whatever be the distance to which they are separated by the motion of the forks. The lower sides of the forks are made in such a manner that the wires can just pass each other without touching; and at the instant of their passage they must coincide so completely as to appear one wire. When this takes place, the index should point to the zero of the scale *a* within the micrometer, each division of which is equal to the interval between any of

MICROMETERS.

the threads of the male screw, and is of course passed over by either of the wires, during one complete revolution of the nut L or M. The graduated heads N and P are each divided into 100 parts, so that the distance between the wires can at any time be ascertained to the $\frac{1}{100}$th part of one of the divisions of the scale *a*. These divisions are generally the fiftieth of an inch each, so that every unit on the graduated head corresponds to the $\frac{1}{5000}$th part of an inch. A third wire *b*, lying in the direction of the screws, bisects the other two wires at right angles, and is intended to point out the direction in which the angle is to be measured. The angle subtended by the wires, when separated to any distance, is found by counting the number of revolutions, and parts of a revolution, of the divided head N or M, which are necessary to make the one wire move up to the other, and coincide with it. The number of seconds passed over by any of the wires, during one revolution of the head N or M, must be ascertained by actual experiment, that is, by measuring a base, and observing the space comprehended between the wires at the end of that base, where they are separated by so many revolutions; or by observing the time employed by an equatorial star in passing from the one wire to the other. When the angle is thus determined which corresponds to any given number of revolutions it may be found by simple proportion for any other number of revolutions; and these results may be conveniently put down in the form of a table, to prevent the necessity of future calculation.

Let it be required, for example, to measure the sun's diameter, and let us suppose that two revolutions of the divided head separate the wires to such a distance that they subtend exactly an angle of sixty seconds. Having directed the telescope to the sun, turn round the micrometer by means of the screw D, till the lower limb of the sun S *s*, fig. 4, just passes along the lowest parallel wire C D. Then turn the nut which moves the other wire A B, till it is at such a distance from C D that the upper limb of the sun just passes along it. The sun S *s* is now comprehended exactly between the wires, and the angle which they subtend is, therefore, a measure of his diameter. Let the wire A B be now moved towards C D till they coincide, and suppose that it requires sixty revolutions of the divided head, and $\frac{45}{100}$ths of a revolution, to produce this coincidence. Then, since two revolutions are equal to sixty seconds, 60·45 revolutions will be equal to 30·235′, or 30′ 13·5″, the diameter of the sun required. The diameter thus measured is obviously perpendicular to the direction of the sun's motion; but, when we wish to measure the diameter which is parallel to the line of his daily motion, we must guide his upper or his lower limb along the wire which bisects the parallel wires, and then separate the wires till the one extremity of the diameter is in contact with the first wire, at the very instant that the other extremity is in contact with the second wire. The motion of the sun, however, renders this observation so extremely difficult, that it is almost impossible to make it with any degree of accuracy.

By attending to the principles upon which this instrument is constructed, it will be easy to discover the numerous sources of error to which it is liable. The difficulty of finding the real zero of the scale, or the instant when the two wires appear to be in contact; the error arising from the want of parallelism in the wires, or from a lateral shake in the forks which carry them; the inflexion of light which takes place when the wires are near each other; the complicated structure of the instrument; the minuteness of the scale and all its parts; but especially the difficulty of procuring screws in which the distance of the thread is always the same, are objections inseparable from the construction of this instrument.

The *lamp micrometer*, contrived by the late Sir William Herschel, appears well calculated for its intended purpose, and is described by the inventor in vol. lxxii. of the Transactions of the Royal Society. A B G C F E, fig. 5, is a stand nine feet high, upon which a semi-circular board *q h o g p* is moveable upwards or downwards, in the manner of some fire-screens, as occasion may require, and is held in its situation by a peg *p*, put into any one of the holes of the upright piece A B. This board is a segment of a circle of fourteen inches radius, and is about three inches broader than a semi-circle, to give room for the handles, *r* D, *e* P, to work. The use of this board is to carry an arm L, thirty inches long, which is made to move upon a pivot at the centre of the circle, by means of a string, which passes in a groove upon the edge of the semi-circle *p g o h q*; the string is fastened to a hook at *o* (not expressed in the figure, being at the back of the arm L), and passing along the groove from *o h* to *q* is turned over a pulley at *q*, and goes down to a small barrel *e*, within the plane of the circular board, where a double-jointed handle *e* P commands its motion. By this contrivance we see the arm L may be lifted up to any altitude from the horizontal position to the perpendicular, or be suffered to descend by its own weight below the horizontal to the reverse perpendicular situation. The weight of the handle P is sufficient to keep the arm in any given position; but, if the motion should be too easy, a friction-spring applied to the barrel will moderate it at pleasure.

In front of the arm L a small slider, about three inches long, is moveable in a rabbet from the end L towards the centre backwards and forwards. A string is fastened to the left side of the little slider, and goes towards L, where it passes round a pulley at *m*, and returns under the arm from *m*, *n*, towards the centre, where it is led in a groove on the edge of the arm, which is of a circular form, upwards to a barrel (raised above the plane of the circular board) at *r*, to which the handle *r* D is fastened. A second string is fastened to the slider, at the right side, and goes towards the centre, where it passes over a pulley *n*, and the weight *w*, which is suspended by the end of this string returns the slider towards the centre, when a contrary turn of the handle permits it to act.

a and *b* are two small lamps, two inches high, one and a half in breadth by one and a quarter

in depth. The sides, back, and top, are made so as to permit no light to be seen, and the front consists of a thin brass folding-door. The flame in the lamp *a* is placed three-tenths of an inch from the left side, three-tenths from the front, and half an inch from the bottom. In the lamp *b* it is placed at the same height and distance measuring from the right side. The wick of the flame consists only of a single very thin lamp-cotton thread; for, the smallest flame being sufficient, it is easier to keep it burning in so confined a place. In the top of each lamp must be a little slit, lengthways, and also a small opening in one side near the upper part, to permit air enough to circulate to feed the flame. To prevent every reflexion of light, the side opening of the lamp *a* should be to the right, and that of the lamp *b* to the left. In the sliding door of each lamp is made a small hole with the point of a very fine needle, just opposite the place where the wicks are burning, so that when the sliders are cut down, and every thing dark, nothing shall be seen but two fine lucid points of the size of the two stars of the third or fourth magnitude. The lamp *a* is placed so that its lucid point may be in the centre of the circular board, where it remains fixed. The lamp *b* is hung to the little slider which moves in the rabbet of the arm, so that its lucid point, in a horizontal position of the arm, may be on a level with the lucid point in the centre. The moveable lamp is suspended upon a piece of brass fastened to the slider by a pin exactly behind the flame, upon which it moves as a pivot. The lamp is balanced at the bottom by a leaden weight, so as always to remain upright, when the arm is either lifted above, or depressed below, the horizontal position. The double-jointed handles *r* D, *e* P, consist of light deal rods ten feet long, and the lowest of them may have divisions marked upon it near the end P, expressing exactly the distance from the central lucid point in feet, inches, and tenths.

From this construction we see that a person at a distance of ten feet may govern the two lucid points, so as to bring them into any required position south or north, preceding or following, from 0° to 90°, by using the handle P, and also to any distance, from six-tenths of an inch to five or six-and-twenty inches, by means of the handle D. If any reflexion or appearance of light should be left from the top or sides of the lamps, a temporary screen, consisting of a long piece of pasteboard, or a wire frame covered with black cloth, of the length of the whole arm and of any required breadth, with a slit of half an inch broad in the middle, may be affixed to the arm by four bent wires projecting an inch or two before the lamps, situated so that the moveable lucid point may pass along the opening left for that purpose.

Fig. 6 represents part of the arm L, half the real size; S the slider; *m* the pulley, over which the cord *x t y z* is returned towards the centre; *v* the other cord going to the pulley *n* of fig. 5; R the brass-piece moveable upon the pin *c*, to keep the lamp upright. At R is a wire riveted to the brass piece, upon which is held the lamp by a nut and screw. Figs. 7 and 8 represent the lamps *a*, *b*, with the sliding doors open, to show the situation of the wicks. W is the leaden weight with a hole *d* in it through which the wire R of fig. 6 is to be passed when the lamp is to be fastened to the slider S. Fig. 9 represents the lamp *a* with the sliding door shut, *l* the lucid point, and *i k* the openings at the top, and *s* at the sides for the admission of air.

Every ingenious artist will soon perceive that the motions of this micrometer are capable of great improvement by the application of wheels and pinions, &c.; but as the principal object is only to be able to adjust the two lucid points to the required position and distance, and to keep them there for a few minutes, while the observer goes to measure their distance, it will not be necessary to say more on the subject.

We have now to show the application of this instrument. It is well known to opticians and others, who have been in the habit of using optical instruments, that we can with one eye look into a microscope or telescope, and see an object much magnified, while the naked eye may see a scale upon which the magnified picture is thrown. In this manner Sir William Herschel generally determined the power of his telescopes; and any one who has acquired a facility of taking such observations, will very seldom mistake so much as one in fifty, in determining the power of an instrument; and that degree of exactness is fully sufficient for the purpose.

The Newtonian form is admirably adapted to the use of this micrometer; for the observer stands always erect, and looks in a horizontal direction, notwithstanding the telescope should be elevated to the zenith. Besides, his face being turned away from the object to which his telescope is directed, this micrometer may be placed very conveniently without causing the least obstruction to the view. Sir W. Herschel observed that, when he used this instrument, he put it at ten feet distance from the left eye, in a line perpendicular to the tube of the telescope, and raised the moveable board to such a height that the lucid point of the central lamp may be upon a level with the eye. The handles lifted up, are passed through two loops fastened to the tube, just by the observer, so as to be ready for his use. It may be proper to state that the end of the tube is cut away so as to leave the left eye entirely free to see the whole micrometer.

Having now directed the telescope to a double star, view it with the right eye, and at the same time with the left see it projected upon the micrometer: then, by the handle P, which commands the position of the arm, raise or depress it so as to bring the two lucid points to a similar situation with the two bars; and, by the handle D, approach or remove the moveable lucid point to the same distance of the two stars, so that the two lucid points may be exactly covered by, or coincide with, the stars. A little practice in this business soon makes it easy, especially to one who has already been used to look with both eyes open.

What remains to be done is very simple. With a proper rule, divided into inches and fortieth parts, take the distance of the lucid points, which may be done to the greatest nicety,

because the little holes are made with the point of a very fine needle. The measure thus obtained is the tangent of the magnified angle under which the stars are seen to a radius of ten feet; therefore, the angle being found and divided by the power of the telescope gives the real angular distances of the centres of a double star.

The late Mr. Ramsden described two valuable micrometers, which he contrived with the view of remedying the defects of those that had been previously constructed. One of these is a catoptric micrometer, and can have no aberration, nor is it liable to any defect arising from the imperfection of the materials or execution; as the extreme simplicity of its construction requires no additional mirrors or glasses to those required for the telescope; and the separation of the image being effected by the inclination of the two specula, and not depending on the focus of any lens or mirror, any alteration in the eye of an observer cannot affect the angle measured. It has also the advantages of an adjustment, to make the images coincide in a direction perpendicular to that of their motion; and also of measuring the diameter of a planet on both sides of the zero, which is of no small advantage to observers, who know how much easier it is to ascertain the contact of the external edges of two images, than their perfect coincidence. A, fig. 10, represents the small speculum of a reflecting telescope, of Cassegrain's construction, to which this micrometer is adapted, divided into two equal parts; one of which is fixed on the end of the arm B; the other end of the arm is fixed on a steel axis X, which crosses the end of the telescope C. The other half of the mirror A is fixed on the arm D, which arm at the other end terminates in a socket *y*, that turns on the axis X; both arms are prevented from bending by the braces *a a*. G represents a double screw, having one part, *e*, cut into double the number of threads in an inch to that of the part *g*; the part *e* having 100 threads in one inch, and the part *g* fifty only. The screw *e* works in a nut F, in the side of the telescope, while the part *g* turns in a nut H, which is attached to the arm B; the ends of the arms B and D, to which the mirrors are fixed, are separated from each other by the point of the double screw pressing against the stud *h*, fixed to the arm D, and turning in the nut H on the arm B. The two arms, B and D, are pressed against the direction of the double screw *e g*, by a spiral spring within the part *n*, by which means all shake or play in the nut H, on which the measurement depends, is entirely prevented.

From the difference of the threads on the screw at *e* and *g*, it is evident that the progressive motion of the screw through the nut will be half the distance of the separation of the two halves of the mirror, and consequently the half mirrors will be moved equally in contrary directions from the axis of the telescope C.

The wheel V, fixed on the end of the double screw, has its circumference divided into 100 equal parts, and numbered at every fifth division, with 5·10, &c. to 100; and the index I shows the motion of the screw with the wheel round its axis, while the number of revolutions of the screw is shown by the divisions on the same index. The steel screw, R, may be turned by the key S, and serves to incline the small mirror at right angles to the direction of its motion.

The other micrometer, invented by Mr. Ramsden, is suited to the principle of refraction, and is thus described by Mr. Partington:—'This micrometer is applied to the erect eye-tube of a refracting telescope, and is placed in the conjugated focus of the first eye-glass; in which position, as the image is considerably magnified before it comes to the micrometer, any imperfection in its glass will be magnified only by the remaining eye-glasses, which in any telescope seldom exceeds five or six times; and besides, the size of the micrometer glass will not be the $\frac{1}{16}$th part of the area which would be required, if it were placed at the object-glass; and yet the same extent of scale is preserved, and the images are uniformly bright in every part of the field of the telescope. This micrometer is represented at fig. 11. A is a convex or concave lens, divided into two equal parts by a plane across its centre; one of these semi-lenses is fixed in a frame B, and the other in the frame E, which two frames slide on a plate H, and are pressed against it by thin plates *a a*; the frames B and E are moved in contrary directions by turning the button D; L is a scale of equal parts on the frame B; it is numbered from each end towards the middle with 12, 20, &c. There are two verniers on the frame E, one at M and the other at N, for the conveniency of measuring the diameter of a planet, &c., on both sides of the zero. The first division, on both these verniers, coincides at the same time with the two zeros on the scale L; and, if the frame is moved towards the right, the relative motion of the two frames is shown on the scale L, by the vernier M; but, if the frame B be moved towards the left, the relative motion is shown by the vernier N.

'This micrometer has a motion round the axis of vision, for the conveniency of measuring the diameter of a planet, &c., in any direction, by turning an endless screw F; and the inclination of the diameter measured with the horizon is shown on the circle *g*, by a vernier on the plate V. The telescope may be adjusted to distinct vision by means of an adjusting screw, which moves the whole eye-tube with the micrometer, nearer or farther from the object-glass, as telescopes are generally made; or the same effect may be produced in a better manner, without moving the micrometer, by sliding the part of the eye-tube *m* on the part *n*, by the help of a screw or pinion. The micrometer is made to take off occasionally from the eye-tube, that the telescope may be used without it.' Vide *Manual of Natural and Experimental Philosophy, by C. F. Partington.*

Mr. Cavallo has contrived a micrometer of very simple and easy construction. It consists of a thin and narrow slip of mother-of-pearl finely divided, and situated in the focus of the eye-glass of a telescope, just where the image of the object is formed. It is immaterial whether the telescope be a refractor or reflector, pro-

vided the eye-glass be a convex lens, and not a concave one as in the Galilean construction.

The simplest way of fixing it is to stick it upon the diaphragm, which generally stands within the tube, and in the focus of the eye-glass. When thus fixed, if you look through the eye-glass, the divisions of the micrometrical scale will appear very distinct, unless the diaphragm is not exactly in the focus; in which case the micrometrical scale must be placed exactly in the focus of the eye-glass, either by pushing the diaphragm backwards or forwards, when that is practicable; or else the scale may be easily removed from one or the other surface of the diaphragm by the interposition of a circular piece of paper or card, or by a bit of wax. This construction is fully sufficient when the telescope is always to be used by the same person; but, when the different persons are to use it, then the diaphragm, which supports the micrometer, must be constructed so as to be easily moved backwards or forwards, though that motion need not be greater than about a tenth or an eighth of an inch. This is necessary, because the distance of the focus of the same lens appears different to the eyes of different persons, and therefore, whoever is going to use the telescope for the measurement of any angle, must first of all unscrew the tube, which contains the eye-glass and micrometer, from the rest of the telescope, and, looking through the eye-glass, must place the micrometer where the divisions of it may appear quite distinct to his eye.

The mother-of-pearl micrometer may be applied to a microscope, and it will thus serve to measure the lineal dimensions of the object. The value of its divisions may be ascertained by placing an object of a known dimension before the microscope, and by observing how many divisions of the micrometer measure its magnified image. For instance, place a piece of paper, which is exactly one-tenth of an inch long, before the microscope; and, if it is found that fifty divisions of the micrometer measure its magnified image, the observer may conclude that each division denotes an extension of $\frac{1}{500}$th part of an inch in the object; for, if fifty divisions measure one-tenth, 500 divisions must measure the whole inch.

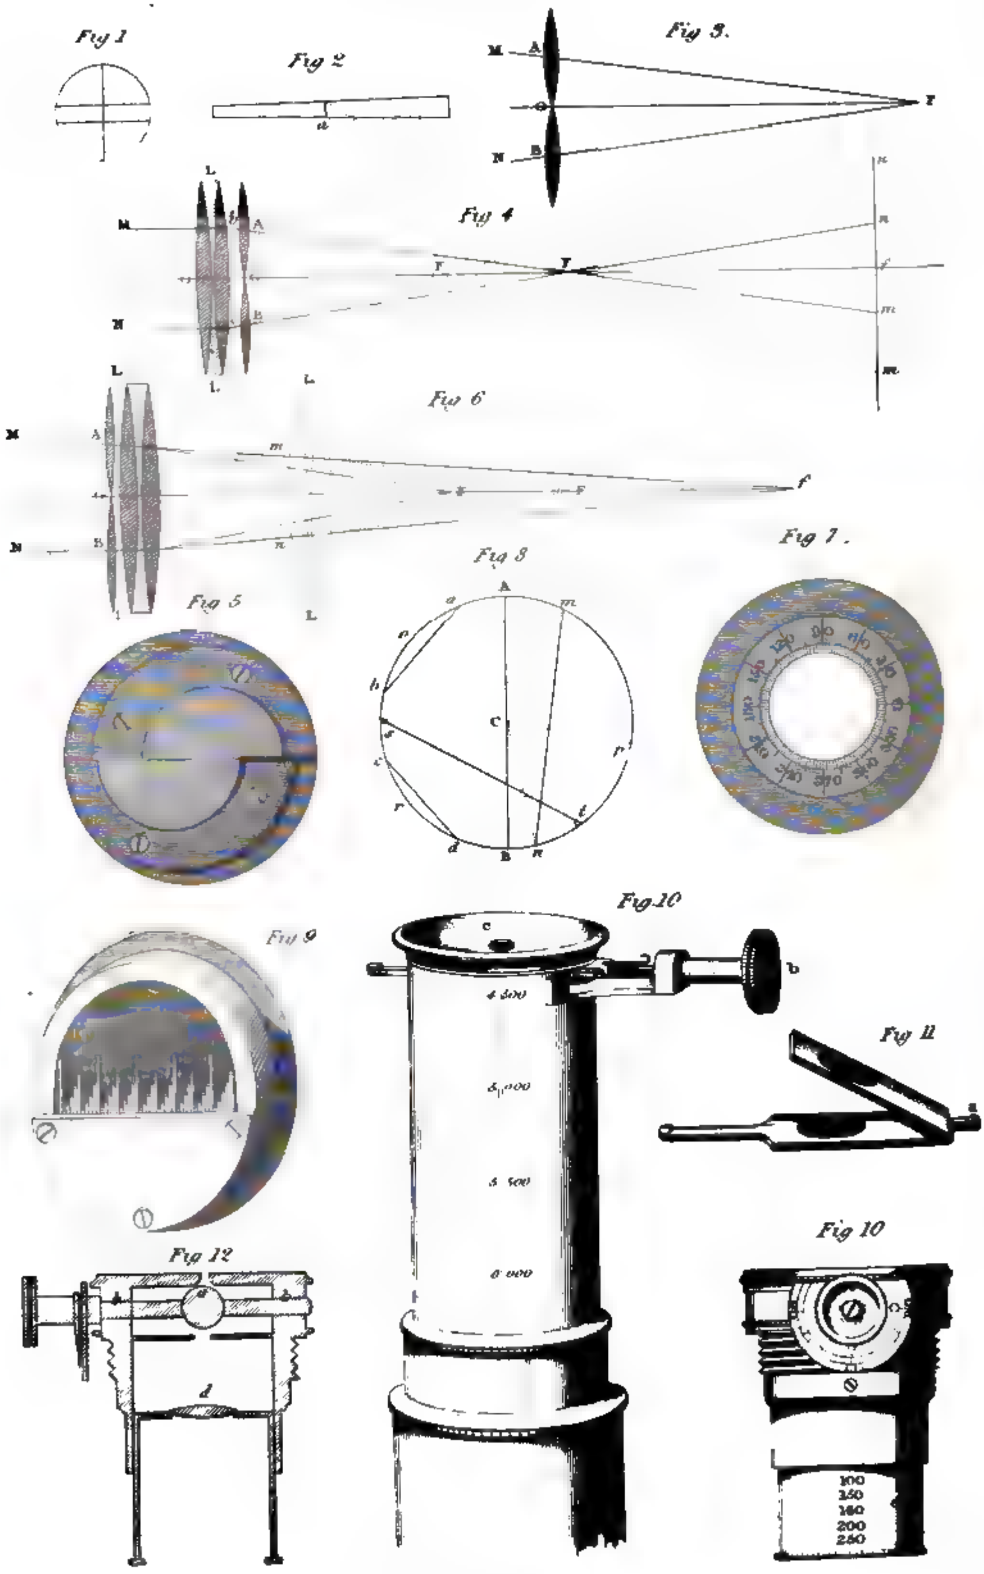
Mother-of-pearl was found by Cavallo, after many trials, to be a much more convenient substance than either glass, ivory, horn, or wood, as it is a very steady substance, the divisions are easily marked upon it, and, when made as thin as common writing-paper, it has a very useful degree of transparency.

Mr. Watt has furnished a description of several micrometers that he contrived, and of which he published an account in the Edinburgh Philosophical Journal. One was suggested about the year 1770, and was used in the surveys for the Crinan and Caledonian Canals.

The instrument he used was a telescope, with an object-glass of twelve inches, and an eye-glass of one inch and a half focus, consequently magnifying eight times. In the focus of the eye-glass there were placed two horizontal hairs, fig. 1. plate 2, and one perpendicular hair. The horizontal hairs were about one-tenth of an inch distant from each other, and as strictly parallel, and at right angles to the perpendicular as possible. A rod being placed upright at twenty chains distance, or any other convenient distance on level ground, an index, consisting of a round disc of about eight inches in diameter, painted white, with a horizontal line of one inch wide, painted on its horizontal diameter with vermilion, was fixed upon the rod about one foot from the ground, and another similar index was moved up and down the rod, until, upon looking through the telescope, the two horizontal hairs covered the red stripes on the lower and upper indexes, the telescope being turned on its axis until the perpendicular hair was parallel to the rod. The indexes being thus covered accurately by the horizontal hairs, the upper index was fixed to the rod, and the distance between the middle of the red stripes on the two indexes was divided upon the rod into twenty parts, representing so many chains, which, with the instrument Mr. Watt used, were upon the rod about four inches and a half each; and, for distances exceeding five chains, this division into equal parts was sufficiently accurate; but for shorter distances it is not strictly so. He therefore fixed a pin at every chain, and, holding up the rod at each of them, made the necessary correction; and, as the focus of the object-glass is also affected by the distance, it is proper to adjust the eye-glass to it at each station. The divisions on the rod being marked with the number of chains they represent, it was only necessary to send an assistant with the rod to any place the distance of which was wanted to be measured, and by signs to make him move the upper index up and down, until the two horizontal hairs covered the red stripes on the upper and lower indexes; the divisions on the rod then showed the distance, which could be ascertained to within less than $\frac{1}{100}$th part of the whole distance, and with a higher magnifying power could be done proportionally more accurate. The rod commonly used was twelve feet long, and consequently could measure thirty chains; but by sliding another rod upon it, so as to lengthen it, he measured greater distances; and, where still greater were wanted, a tape was stretched horizontally, and turning the telescope on its axis, made the single hair parallel to it, fixing one index at the end of the tape, and sliding the other along it subtended the distance between the wires. Mr. Watt then measured the subtended tape with the rod, and so ascertained the distance.

It is plain that this instrument possesses the advantage of measuring all distances with equal accuracy, until the imperfection of vision at great distances interposes, as the scale on which they are measured expands with the distances, and in uneven ground it possesses more accuracy than the chain, and is very valuable in measuring distances from one hill to another, and across bays of the sea, where the chain cannot be used.

Another micrometer, with a prism, Mr. Watt invented about that time; it consisted of a thin prism, with its surfaces nearly parallel, or inclined one degree or two as in fig. 2. This prism was



London Published by Thomas Tegg, 73 Cheapside

J. Shury sculp

cut by a diamond into two parts, which, when they were fixed in the same plane, refracted all the rays which passed through them equally; but one of them remaining fixed, and the other moving on a centre at *a*, according to the dotted line, would refract that portion of the rays which passed through it more than those which passed through the fixed part, and, being placed in the focus of the object-glass of a telescope, two images were formed of each object, by which its diameter could be measured. An index, and divided sector of a circle, served to measure the comparative refractions.

'The cross-hair micrometer, as described,' observes Mr. Watt, 'leaving me too much in the power of my assistants, where the distances were greater than permitted me to read off the number of chains on the rod myself, I thought of another about 1772, which consisted of a telescope with an object glass of a long focus, viz. three or four feet; this was placed in a tube with a slit in one side of it, nearly as long as the focus of the telescope, and the object-glass being fitted to a short tube, which slid from end to end of the slit, could be moved backwards and forwards by means of a piece of metal fixed to the short tube, and coming out through the slit; a glass of six to nine inches focus was all fixed in the outer tube, of the nature of what is called a field-glass, and to this was added an eye-glass, with a cross hair piece in its focus.

'Now it is evident that, if the object-glass be moved nearer the field-glass, their common focus will be shortened, and the image at the cross-hairs diminished proportionally, until the glasses come into contact, when their common focus will be shorter than that of the field-glass alone; and two indexes fixed upon a rod being subtended by the cross hair at any given distance, the same rod with its indexes being removed nearer the observer, upon sliding the object-glass nearer the eye, they may again be subtended by the cross-hairs, and a scale on the side of the tube will show the comparative distance they have been removed; and, the distance of the first object being known, that of the second will also be so. This scale could not, however, be a scale of equal parts, but one which could easily be laid down.'

The common divided object-glass micrometer consists of two semi-lenses A B, fig. 3, of the same focal length, formed by dividing a convex lens into two equal parts, by a plane which passes through its axis. The centres of these semi-lenses are made to separate and approach each other, by means of a screw or pinion along the line A B; and the distance of their centres is measured upon a scale subdivided by a vernier, or, as in the wire micrometers, by a graduated head fixed upon the screw.

If it be required to measure the angle subtended by two objects, M, N, the semi-lenses are separated till the two images of these objects are in contact, or till the image of M, formed by the semilens A, appears to be in contact with the image of N, formed by the semilens B. When this happens, the angle subtended by the objects is equal to the angle subtended by A B, the distance of the centres of the semilenses at the point F, or the focus of the lenses where the contact of the image takes place. It is manifest that an image of M will be formed in the line A F, and at F the focus of rays diverging from M. In like manner an image of N will be formed in the line B F, and at F the focus of rays proceeding from the radiant point N. Hence it is obvious that the angle subtended at F, by M N, is the same as the angle subtended by A B at F. The angle A F B may be easily found trigonometrically, the sides A B and O F being known; but, as this angle is generally very small, it may, without any perceptible error, be considered as proportional to the subtense A B, or the distance between the centres of the semilenses. By determining, therefore, experimentally, the angle which corresponds to any distance A B of the semilenses, we may by simple proportion find the angle for any other distance.

The new divided object glass micrometer contrived by Dr. Brewster consists of an achromatic object glass L L, fig. 4, having two semilenses A B, represented in fig. 5, moveable between it and its principal focus *f*. These semilenses are completely fixed, so that their centres are invariably at the same distance; but the angle subtended by the two images which they form is varied by giving them a motion along the axis O *f* of the lens L L. When the semilenses are close to L L the two images are much separated, and form a great angle; but, as the lenses are moved towards *f*, the centres of the images gradually approach each other, and the angle which they form is constantly increasing. By ascertaining, therefore, experimentally, the angle formed by the centres of the images, when the semilenses are placed close to L L, and also the angle which they subtend when the semilenses are at *f*, the other extremity of the scale, we have an instrument which will measure with the utmost accuracy all intermediate angles.

In constructing this micrometer, for astronomical purposes, the semilenses may be made to move only along a portion of the axis O *f*, particularly if the instrument be intended to measure the diameters of the sun and moon, or any series of angles within given limits. By increasing the focal length of the semilenses, or by diminishing the distance between the centres, the angles may be made to vary with any degree of slowness, and of course each unit of the scale will correspond to a very small portion of the whole angle. The accuracy and magnitude of the scale, indeed, may be increased without limit; but it is completely unnecessary to carry this any farther than till the error of the scale is less than the probable error of observation.

Let us now examine the theory of this micrometer, and endeavour to ascertain the nature of the scale for measuring the variations of the angle. For this purpose let L L, fig. 4, be the object-glass which forms an inverted image, *m n*, of the object M N, and let the semilenses A B, having their centres at an invariable distance, be interposed between the object-glass and its principal focus, in such a manner that their centres are equidistant from the axis O *f*. Now it is obvious that the size of the image *m n* is propor-

tional to the size of the object MN; and, as the angle subtended by MN depends upon its size, the magnitude of the image mn may, in the case of small angles, be assumed as a measure of the angle subtended by MN. As the rays which proceed from the point M are all converged to m, by means of the lens LL, the ray bA, which passes through the centre of the semilens A, must of course have the direction bm; and, as it suffers no refraction in passing through the centre of A, it will proceed in the same direction bAm, after emerging from the semilens, and will cross the axis at F. For the same reason the ray c B, proceeding from N, and passing through the centre of B, will cross the axis at F as it advances to n. If the distance of F from A and B happens to be equal to the focal length of the lenses A and B, when combined with LL, distinct images of M and N will be formed at F, and they will appear to touch one another; and the line mn, being the size of the image that would have been formed by the lens LL alone, will be a measure of the angle subtended by the points MN. If the point F, where the lines Am, Bn, cross the axis, should not happen to coincide with the focus of the lenses A, B, when combined with LL, then let this focus be at F′, nearer A and B than F. Draw the lines AF′m, BF′n, then it is obvious that, if the angle subtended by MN were enlarged so as to be represented by $n'm'$, instead of nm, or so that the lens LL alone would form an image of it equal to $n'm'$, the point of intersection F would coincide with the focus F′; so that in every position of the lenses A, B, with respect to LL, the points MN may always be made to subtend such an angle that, when they are placed before the telescope, the points FF′ will coincide, and consequently the images of the points MN will be distinctly formed at F′, and will be in contact. Whenever this happens the space nm will be a measure of the angle thus subtended by MN. Hence it follows that, whatever be the position of the semilenses AB, on the axis Of, the rays bA, cB, which pass through the centres of the semilenses, will cross the axis at some point F, corresponding with the focus of rays diverging from MN, and will mark out the size of the image $n'm'$, and consequently the relative magnitude of the angle subtended by the two points M, N.

From the equality of the vertical angles AF′B, n'F′m', and the parallelism of the lines AB, $n'm'$, we shall have

$$n'm' : AB = fF' : GF',$$

and calling $fF' = b$, and considering that $GF' = \frac{Fb}{F+b}$, F being the focal length of the semilenses, we have

$$n'm' : AB = b : \frac{Fb}{F+b}, \text{ and consequently}$$

$$n\,m' = AB + \frac{AB \times b}{F}.$$

Now, calling AB = 2, F = 10, and $b = 1, 2, 3$, successively, we shall obtain

$$n'm' = 2 + \frac{2 \times 1}{10} = 2{\cdot}2$$

$$n\,m' = 2 + \frac{2 \times 2}{10} = 2{\cdot}4$$

$$n'm' = 2 + \frac{2 \times 3}{10} = 2{\cdot}6;$$

from which it appears that, when b is in arithmetical progression, the angle $n'm'$ varies at the same rate; and consequently the scale, which measures the variations of the angle subtended by the centres of the two images, is a scale of equal parts.

This instrument undergoes a very singular change when constructed, as in fig. 6, so that the semilenses are outermost and immoveable, while another lens, LL, is made to move along the axis Gf. In this case a double image is formed as before, but the angle subtended by the centres of the images never suffers any change during the motion of the lens LL along the axis of the telescope. If the two images are in contact when the lens LL is close to the semilenses, they will continue in contact in every other position of LL; but the magnitude of the images is constantly increasing during the motion of LL towards f, the principal focus of the semilenses. The reason of this remarkable property will be understood from fig. 6, where MN are two objects placed at such an angle that the rays, passing through the centres AB of the semilenses, cross the axis at F, and will consequently be in contact. If the lens LL is removed to the position L′L′, the rays Mm, Nn, which are incident upon it at the points m and n, having the same degree of convergency as before, will be refracted to F′, the focus of the combined lenses for rays diverging from MN. Two distinct images of the object will therefore be formed at F′, and these images will still be in contact. In like manner it may be shown, that whatever be the position of the lens LL between G and f, the rays Mf, Nf, will cross the axis at a point coinciding with the focus of the combined lenses, and will there form two images always in contact. Hence it follows that, though the magnifying power of the instrument is constantly changing with the position of the lens LL, yet the angle subtended by the centres of the two images never suffers the least variation.

The *circular micrometer* is an instrument which has been, for many years past, much used on the continent, and is still held in high and deserved estimation there by astronomers of the first rank. From the simplicity of its construction, and the facility with which it may be used in any position of the telescope, it is frequently preferred, even in public and national observatories, to micrometers of a more complex nature, which require to be adjusted to the equatorial motion of the star. Moreover there is no necessity for its being illuminated; on which account it is peculiarly adapted to the observation of comets and small stars; and it is, indeed, to these two classes of the heavenly bodies that its application is now principally confined; although some astronomers of great eminence have considered that it is capable of equal accuracy to the wire micrometers. To voyagers and others it will prove of considerable advantage. The smallness of its size (not being much larger than a shilling) renders it very convenient for carriage; and the simplicity of its construction prevents any liability to injury.

Astronomy is indeed more indebted to this little instrument than is perhaps generally known. Three out of the four new planets which have been discovered in the present century were discovered with very small telescopes, and their motions watched, and the elements of their orbits deduced from observations made with the circular micrometer only; whereby astronomers were enabled to look out for them with certainty at the time of their re-appearance at the next oppositions. And at the present day it is almost the only instrument used on the continent for the observation of comets. To the labors of Olbers, Bessel, and Frauenhofer, we are indebted for the high reputation which this instrument has attained. To the two former for the talent which they have displayed in explaining the analysis by which the observations may be reduced; and to the latter for the recent improvements which he has introduced in the construction of the instrument.

M. Frauenhofer's micrometers are formed by means of very fine lines cut on glass with a diamond point in a peculiar manner, and placed in the focus of the telescope. One of these micrometers consists of concentric circular lines, drawn at unequal distances from each other; and the other consists of straight lines crossing each other at a given angle. The mode of cutting these lines has furnished M. Frauenhofer with a method of illuminating them, which, at the same time that it renders the lines visible, leaves the other part of the field of the telescope in darkness; so that the transits of the smallest stars may be observed by means of these micrometers, the lines appearing like so many silver threads suspended in the heavens.

The circular mother-of-pearl micrometer, which Dr. Brewster has often used, both in determining small angles in the heavens and such as are subtended by terrestrial objects, is represented in fig. 7, which exhibits its appearance in the focus of the first eye-glass. The black ring which forms part of the figure is the diaphragm, and the remaining part is an annular portion of mother-of-pearl, having its interior circumference divided into 360 equal parts. The mother-of-pearl ring, which appears connected with the diaphragm, is completely separate from it, and is fixed at the end of a brass tube, which is made to move between the third eye-glass and the diaphragm, so that the divided circumference may be placed exactly in the focus of the glass next the eye. When the micrometer is thus fitted into the telescope, the angle subtended by the whole field of view, or by the diameter of the innermost circle of the micrometer, must be determined either by measuring a base, or by the passage of an equatorial star; and the angles subtended by any number of divisions or degrees will be found by a table constructed in the following manner:—

Let A $m\ p\ n\ b$, fig. 8, be the interior circumference of the micrometer scale, and let $m\ n$ be the object to be measured. Bisect the arch $m\ n$ in p, and draw C m C p C n. The line C p will be at right angles to $m\ n$, and therefore $m\ n$ will be twice the sine of half the arch $m\ p\ n$. Consequently A B $m\ n$ = Rad. Sine of $\frac{1}{2}\ m\ p\ n$; therefore $m\ n \times \text{R} = \sin.\ \frac{1}{2}\ m\ p\ n \times \text{A B}$, and $m\ p\ n = \frac{\sin.\ \frac{1}{2}\ m\ p\ n}{\text{R}} \times \text{A B}$, a formula by which the angle subtended by the chord of any number of degrees may be easily found. The first part of the formula, viz. $\frac{\sin.\ \frac{1}{2}\ m\ p\ n}{\text{R}}$ is constant, while A B varies with the size of the micrometer, and with the magnifying power which is applied. The following table, therefore, has been computed, which contains the value of the constant part of the formula for every degree or division of the scale:—

Degrees.	Constant part of the Formula.	Degrees.	Constant part of the Formula.	Degrees.	Constant part of the Formula.	Degrees.	Constant part of the Formula.	Degrees.	Constant part of the Formula.

In order to find the angle subtended by any number of degrees we have only to multiply the constant part of the formula corresponding to that number in the table by A B, or the angle subtended by the whole field. Thus, if A B is 30′, the angle subtended by 1° of the scale will be $30' \times \cdot0087 = 15\frac{2}{3}''$, and the angle subtended by 40° will be $30' \times \cdot342 = 10'\ 15''.6$; and by making the calculation it will be found that, as the angle to be measured increases, the accuracy of the scale also increases; for, when the arch is only 1° or 2°, a variation of 1° produces a variation of about 16″ in the angle; whereas, when the arch is between 170° and 180°, the variation of a degree does not produce a change of much more than 1″ in the angle.

The *single-lens* micrometer, contrived by Dr. Wollaston, must now be adverted to. Having had occasion to measure some very small wires, with a greater degree of accuracy than he was enabled to do by any instrument hitherto made use of for such purposes, he was led to contrive other means that might more effectually answer the end proposed. The instrument to which Dr. Wollaston had recourse is furnished with a single lens of about one-twelfth of an inch focal length. The aperture of such a lens is necessarily small; so that, when it is mounted in a plate of brass, a small perforation can be made by the side of it in the brass as near to its centre as one-twenty-fifth of an inch. When a lens thus mounted is placed before the eye, for the purpose of examining any small object, the pupil is of sufficient magnitude for seeing distant objects at the same time through the adjacent perforation; so that the apparent dimensions of the magnified image might be compared with a scale of inches, feet, or yards, according to the distance at which it might be convenient to place it. A scale of smaller dimensions attached to the instrument will, however, be found preferable on account of the steadiness with which the comparison may be made; and it may be seen with sufficient distinctness by the naked eye, without any effort of nice adaptation, by reason of the smallness of the hole through which it is viewed. The construction that Dr. Wollaston chose for the scale is represented in fig. 9. It is composed of small wires, about one-fiftieth of an inch in diameter, placed side by side, so as to form a scale of

equal parts, which may with ease be counted by means of a certain regular variation of the lengths of the wires.

The external appearance of the whole instrument is that of a common telescope, consisting of three tubes. The scale occupies the place of the object-glass, and the little lens is situated at the smaller end, with a pair of plain glasses sliding before it, between which the subject of examination is to be included. This part of the apparatus is shown separately in fig. 11. It has a projection at *a*, with a perforation, through which a pin is inserted to connect it with a screw represented at *b*, fig. 10. This screw gives lateral motion to the object, so as to make it correspond with any particular part of the scale. The lens has also a small motion of adjustment by means of the cap *c*, which renders the view of the magnified object distinct.

Before the instrument is completed it is necessary to determine with precision the indications of the scale, which must be different according to the distance to which the tube is drawn out. In Dr. Wollaston's instrument one division of the scale corresponds to $\frac{1}{10000}$ of an inch when it is at the distance of 16·6 inches from the lens; and, since the apparent magnitude in small angles varies in the simple inverse ratio of this distance, each division of the same scale will correspond to $\frac{1}{5000}$ at the distance of eight inches and three-tenths, and the intermediate fractions $\frac{1}{6000}$, $\frac{1}{7000}$, &c., are found by intervals of 1·66 inch marked on the outside of the tube. The basis on which these indications were founded, in this instrument, was a wire carefully ascertained to be $\frac{1}{200}$ of an inch in diameter, the magnified image of which occupied fifty divisions of the scale, when it was at the distance if 16·6 inches, and hence one division $=\frac{1}{50\times 200}=\frac{1}{10000}$. Since any error in the original estimate of this wire must pervade all subsequent measures derived from it, the substance employed was pure gold drawn till fifty-two inches in length weighed exactly five grains. If we assume the specific gravity of gold to be 19·36, a cylindrical inch will weigh 3837 grains, and we may thence infer the diameter of such a wire to be $\frac{1}{200}$ of an inch, more nearly than can be ascertained by any other method. For the sake of rendering the scale more accurate, a similar method was in fact pursued with several gold wires, of different sizes, weighed with equal care, and the subdivisions of the exterior scale were made to correspond with the average of their indications.

In making use of this micrometer, for taking the measure of any object, it would be sufficient at any one accidental position of the tube to note the number on the outside as denominator, and to observe the number of divisions and decimal parts which the subject of examination occupies, on the interior scale, as numerator of a fraction expressing its dimensions in proportional parts of an inch; but it is preferable to obtain an integer as numerator, by sliding the tube inward or outward till the image of the wire is seen to correspond with some exact number of divisions, not only for the sake of the greater simplicity in the arithmetical computation, but because we can by the eye judge more accurately of actual coincidence, than of the comparative magnitudes of adjacent intervals.

The smallest quantity, which the graduations of this instrument profess to measure, is less than the eye can readily appreciate in sliding the tube inward or outward. If, for instance, the object measured be nearly $\frac{1}{5000}$, it may appear $\frac{1}{10000}$, or $\frac{1}{9800}$, in which case the doubt amounts to one-fiftieth part of the whole quantity. But the difference is here exceedingly small in comparison to the extreme division of other instruments where the nominal extent of its power is the same. A micrometer with a divided eye-glass may profess to measure as far as $\frac{1}{10000}$ of an inch; but the next division is $\frac{1}{10000}$ or $\frac{1}{5000}$; and, though the eye may be able to distinguish that the truth lies between the two, it receives no assistance within one-half part of the larger measure.

We may now notice the micrometer made of *rock crystal* suggested by Mr. Dollond. Rock crystal having been applied to telescopes in various ways, for the purposes of micrometrical measurements, particularly that which is recommended by M. Arago, induced him to consider if a more simple mode of applying the crystal could not be discovered, and the following account of its application to the eye-tube of a telescope is the result.

The improvement consists in making a sphere or lens from a piece of rock crystal, and adapting it to a telescope in the place of the usual eye-glass; and, from its natural double refracting power, rendering it useful as a micrometer.

The advantages of thus applying the crystal are, in the first place, the great saving of the time required to find the proper angle for cutting the crystal; also of cutting the prisms to their proper angles, and working their surfaces with sufficient accuracy to render them useful as micrometers, in the manner that is recommended by M. Arago, Dr. Wollaston, and others.

Upon this plan it is only necessary to select a piece of perfect crystal; and, without any knowledge of the angle that will give the greatest double refraction, to form the sphere of a proper diameter for the focal length required.

The second advantage is derived from being able to take the angle on each side zero, without reversing the eye-tube; also of taking intermediate angles between zero and the greatest separation of the images, without exchanging any part of the eye-tube, it being only required to move the axis in which the sphere is placed.

Thirdly, it possesses the property of an eye-tube or lens that is not intended for micrometrical measurements; for, when the axis of the crystal is parallel to the axis of the object-glass of the telescope, only one image will be formed, and that will be as distinctly formed as with any lens that does not posses the double refracting property.

The eye-tube is so constructed that the plane through which the two images move can be placed parallel to the line in the object which is to be measured; and, if this motion is furnished with a divided circle, it will correctly answer the purpose of a position micrometer.

The value of the scale is found from the known diameter of any distan object, and will

vary in proportion to the magnifying powers of the eye-tube; its value increasing in proportion to the increase of those magnifying powers.

Fig. 12 is a section of the eye-tube; and fig. 13 a general view of the same; both of the full size.

The sphere, or lens, *a*, fig. 12, is formed of rock crystal, and placed in half holes, from which is extended the axis *b b*, with an index attached; which index registers the motion of the sphere, the extent of that motion being shown upon the divided face C, fig. 13. The sphere is so placed in the half holes that, when its natural axis is parallel to the axis of the telescope, only one image of the object is seen. In the other direction, or that which is at right angles to the axis of motion, it must be so placed that when it is moved the separation of the images, viz. the ordinary and extraordinary, may be parallel to that motion. The method of acquiring this adjustment is, by turning the sphere in the half holes parallel to its own axis.

The field of view of the eye-tube is increased, and the magnifying power varied, by the introduction of the lens *d*, fig. 12, between the sphere and the primary image of the object-glass; and its distance from the sphere will be in proportion to the magnifying power required; the magnifying powers are engraved upon the eye-tube at *e*, and will vary in proportion to the focal length of the object-glass to which the eye-tube is applied. Those marked in the figure are for an object-glass of forty-four inches in focal length.

The object of Mr. Babbage's new *zenith* micrometer is to supersede the necessity of extreme accuracy in the divisions. The principle on which this instrument depends may be readily comprehended by imagining a parallelogram, admitting of free motion about its four angles, to be placed with two of its sides in a horizontal position, and the whole in a vertical plane, and a telescope to be fixed at right angles to the lower horizontal bar of this parallelogram. Here every motion of one of the perpendicular bars of the instrument round its upper joint will not change the angle which the telescope makes with the meridian; but will merely remove it into a new position in which it will point to the same object in the heavens. But, if either of the horizontal bars of the instrument be lengthened by a very small quantity, this parallelism of the telescope will no longer be preserved; but any movement of the upright bars round their axes will not only remove the telescope from its position, but will cause it to form a very small angle with its former direction. The magnitude of that angle will depend on the alteration in the length of the arm of the parallelogram, and also on the angle which that arm makes with its first direction. The arc which is actually measured in the heavens, by means of this instrument, is determined by a formula in which the sum of three arcs is taken from the semicircumference, one of them resulting from the actual observation; the other two from a cosine and a tangent, ascertainable by computation from the theorem itself. In an extensive use of this micrometer tables may easily be formed to faci·tate the computation.

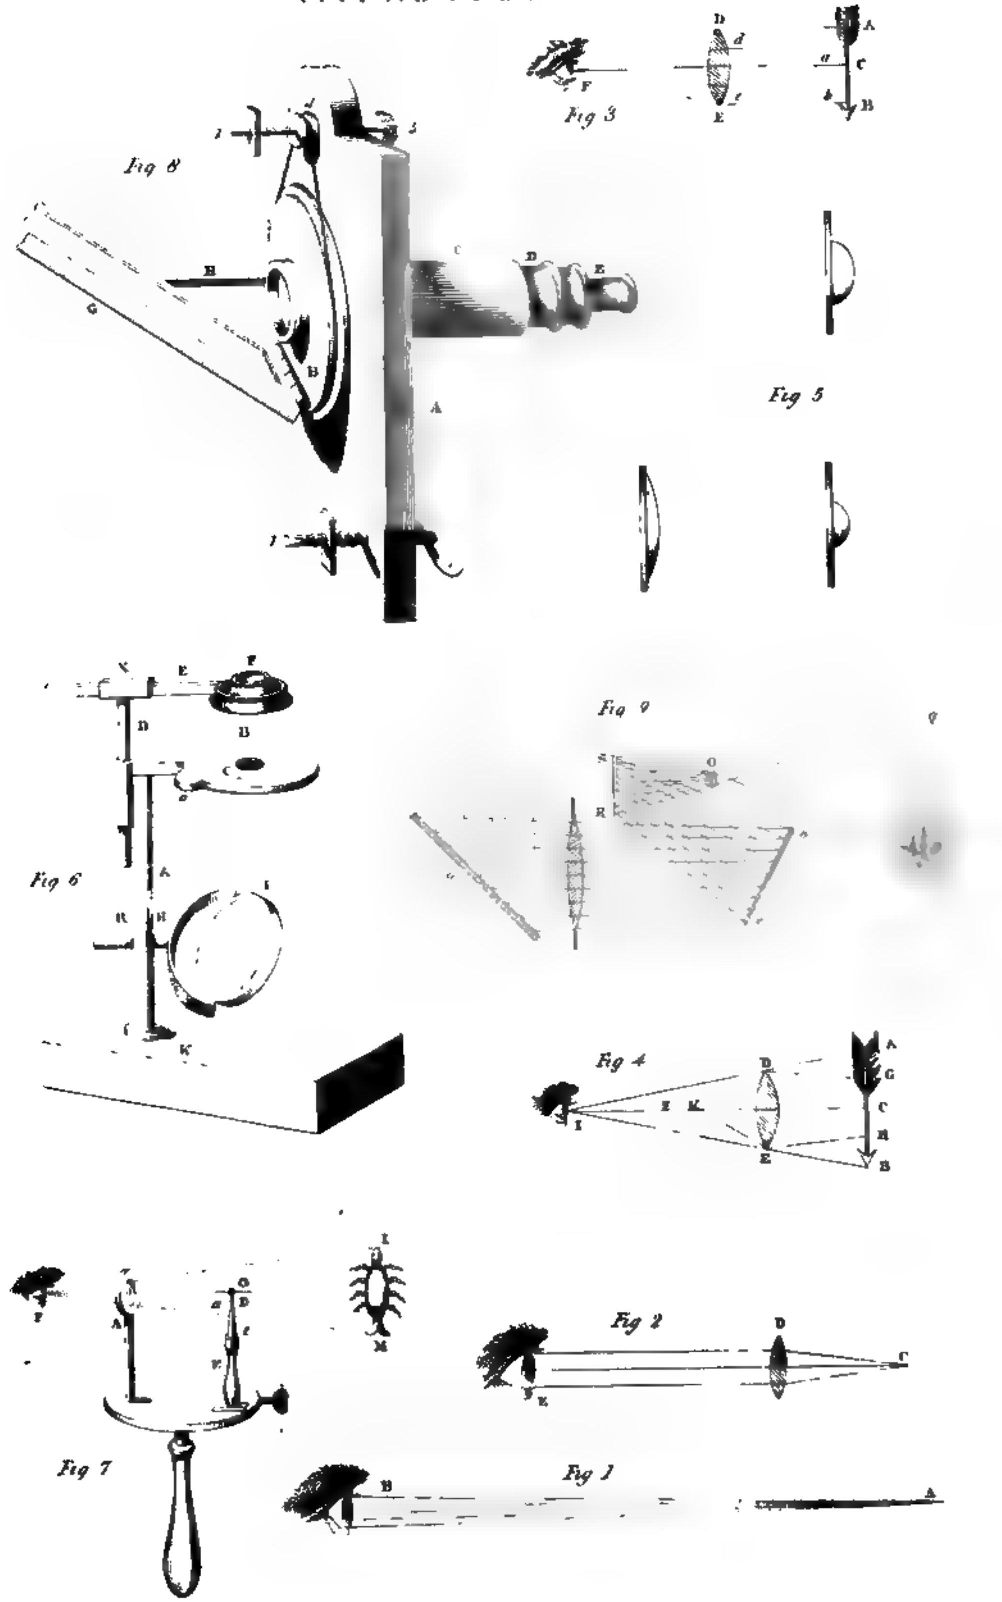
It may now be advisable to examine the *fibres* proper for micrometers, and on the method of adjusting them to the eye-piece.

In the micrometer constructed by Huygens the object whose angle was required was comprehended between the edges of two plates of brass. Silver wires, and sometimes hairs, were afterwards substituted instead of the plates, and continued in use till about the end of the last century. The finest silver wire ever made was drawn in France to the thickness of $\frac{1}{1000}$ of an inch. The plates used for this purpose, and the secret of making them, are said to have been lost amid the convulsions of the revolution. The smallest wire which is made in this country does not exceed $\frac{1}{500}$th of an inch.

The impossibility of obtaining wire of a diameter sufficiently minute for micrometers induced Felix Fontana, in 1775, to recommend the spider's web as an excellent substitute for silver wire. This suggestion of Fontana, however, did not excite much notice, till the use of the spider's web was introduced by the late celebrated Mr. Troughton, who found this fibre to be so fine, opaque, and elastic, as to answer all the objects of practical astronomy. We are informed, however, by this distinguished artist, that it is only the stretcher, or the long line which supports the web, that possesses these valuable properties. The other parts of the web, though equally fine and elastic, are very transparent, and therefore completely unfit for micrometrical purposes. The difficulty of procuring the proper part of the spider's web has compelled many opticians and practical astronomers to employ the raw fibre of unwrought silk, or, what is much worse, the coarse silver wire which is manufactured in this country. But, whatever be the comparative advantages of these different substances, they are all liable to the error arising from the inflexion of light, which renders it impossible to ascertain the exact contact between the fibre and the luminous body. This disadvantage has been experienced by every astronomical observer and has always been considered as inseparable from the wire micrometer. After numerous trials, Dr. Brewster succeeded in obtaining a delicate fibre, which appears to remove the error of inflexion while it possesses the requisite properties of opacity and elasticity. This fibre is glass, which is so exceedingly delicate that it can be drawn to any degree of fineness, and can always be procured and prepared with facility; a circumstance of no small importance to the practical astronomer, who is frequently obliged to send his micrometers to a great distance when they require to be repaired.

When the vitreous fibre is formed, and stretched across the diaphragm of the eye-piece of a telescope, it will appear perfectly opaque, with a delicate line of light extending along its axis. This central transparency arises from the refraction of the light which falls upon the edges of the cylindrical fibre, and therefore the diameter of the luminous streak must vary with that of the fibre itself. In a micrometer which Dr. Brewster fitted up in this way the glass fibres are about the 1200th part of an inch in diameter, and the fringe of light which stretches across

MICROSCOPE.



J. Shury Sculp

London Published by Thomas Tegg & Son 73, Cheapside

their axis, is distinctly visible, though it does not exceed in diameter the $\frac{1}{3000}$th part of an inch. In using these fibres for measuring the angle subtended by two luminous points, whether they be two stars, or the opposite extremities of a luminous disc, we may, as has hitherto been done, separate the fibres till the luminous points are in contact with their interior surfaces; but, in order to avoid the error arising from inflexion, Dr. B. proposes that the separation should be continued till the rays of light issuing from the luminous points dart through the transparent axes of the fibres. The rays, thus transmitted, suffer no inflexion in passing through the fibre to the eye; and, besides this advantage, we have the benefit of a delicate line, about one-third of the diameter of the fibre itself.

On some occasions Dr. Brewster employed threads of melted sealing-wax, which may be made extremely fine, though not of such a regular diameter as silver wire, or the fibres of glass. It is a very singular fact, that one of these fibres of wax was exposed, without injury, to the heat of the sun, concentrated in the focus of an object-glass, with an aperture of 2·3 inches, and twenty-nine inches in focal length.

These fibres are placed in delicate parallel grooves formed upon the diaphragm of the first eye-glass, and may be fixed in their places for temporary purposes by a thin layer of bees-wax; but, when they are required to be kept at an invariable distance, it is safer to pinch them to the diaphragm by a small screw-nail near the extremity of each wire.

The diaphragm should be constructed so as to move along the axis of the eye-piece, in order that the fibres may be placed exactly in the anterior focus of the first eye-glass; and, before any observation is made, the eye of the observer ought to be fixed for a short time upon the fibres alone, till it is accommodated to that distance; and, while it is thus fixed, distinct vision should be produced by the motion of the eye-tube. By attending to this suggestion, which is of great practical importance, the rays that diverge from the fibres, and those that diverge from the distinct image, will unite on the same points of the retina. From the great facility which the eye possesses of adjusting itself to different distances, the adaptation of that organ, to the fibres and to the image, could not have been effected by looking at the image alone, while distinct vision was produced by the motion of the eye piece; for, as the eye has not any permanent focus like a lens, the image might appear distinct before the pencils of rays had actually converged to a point; and, when this does happen, the rays proceeding from the fibres cannot unite with those proceeding from the image on the same points of the retina.

When the micrometer is employed in terrestrial observations the end of the eye-tube, into which the observer looks, should be furnished with an aperture smaller than that which is used for common purposes, and this small aperture should be used when the sun shines, or when the light of the day is very great. If the fibres happen to be small, they will either cease to become visible in very strong light, or will appear to have a kind of vibratory motion which injures the eye of the observer, and prevents him from making the observation. Hence it becomes necessary to diminish the light by means of a small aperture.

Professor Wallace, of the Royal Military College, has suggested the employment of asbestos fibres in lieu of the fine wire or spider's web; and a filament about $\frac{1}{5000}$ of an inch in diameter, having been applied to a telescope, was found to answer very perfectly the purpose for which it was intended.

The inventive genius of Dr. Wollaston has, however, far outstripped those who preceded him in the production of a micrometer fibre. The contrivance by which it is effected, is so ingenious, and promises to be productive of such valuable results, that it may be advisable to notice the account of the process employed by this philosopher:—

The extremity of a platinum wire having been fused into a globule nearly one-fourth of an inch in diameter, was next hammered out into a square rod, and then drawn again into a wire $\frac{1}{253}$ of an inch in diameter. One inch of this wire duly coated with silver, was drawn till its length was extended to 182 inches; consequently the proportional diminution of the diameter of the platina will be expressed by the square root of 182, so that its measure had become $\frac{1}{253 \times 13 \cdot 5} = \frac{1}{3425}$. The specific gravity of the coated wire was assumed to be 10·5; and since the weight of 100 inches was 114 grains, its diameter was inferred to be $\frac{1}{42 \cdot 8}$th of an inch, or just eighty times that of the platina contained in it.

MICROPUS, bastard cudweed, a genus of the polygamia necessaria order, and, syngenesia class of plants; natural order forty-ninth, compositæ; receptacle paleaceous: CAL. calyculated; there is no radius of the corolla. The female florets are wrapped in the scales of the calyx. There are two species; viz.

1. M. erectus, and

2. M. supinus. The latter only is cultivated in gardens. It is an annual plant, growing naturally in Portugal, in places near the sea. The root sends out several trailing stalks, about six or eight inches long, which are garnished with small, oval, silvery leaves, whose bases embrace the stalks. The flowers come out in clusters from the wings of the stalks, and are very small, and of a white color. It flowers in June and July: and is frequently preserved in gardens on account of its silvery leaves. It is easily propagated by seed sown in autumn, and requires no other culture but to be kept free from weeds.

MICROSCOPE.—This instrument has tended most materially to enlarge the boundaries of our knowledge in almost every branch of natural history. Its invention is attributed by the celebrated Dutch mathematician, Huygens, to a countryman of his, named Drebell (for it must be observed that it was entirely lost in the middle ages). He constructed them about the year 1621, or thirty-one years after the invention of the telescope.

According to Borelli, the microscope was invented by Jansen, the reputed contriver of the

telescope, who presented some instruments of his first construction to prince Maurice, and Albert archduke of Austria. These instruments were six feet in length, and consisted of a tube of gilt copper, one inch in diameter, supported by thin brass pillars, in the shape of dolphins, on a base of ebony which was adapted to hold the objects to be examined. Of the internal construction of this microscope we have no precise account; though there is reason to think that it was nothing more than a telescope converted into a compound microscope.

The construction both of single and compound microscopes has, within the last fifty years, been brought to a degree of perfection; and for all the purposes of amusement, and general observation, these instruments may be considered as sufficiently perfect. But when we employ the microscope as an instrument of discovery, to examine those phenomena of the natural world which are beyond the reach of unassisted vision, and when we use it in ascertaining the anatomical and physiological structure of plants, insects, and animalcula, we soon find that a limit, apparently insuperable, is set to the progress of discovery, and that it is only some of the ruder and more palpable functions of these evanescent animals that we are able to bring under observation. Naturalists, indeed, are less acquainted with the organisation of the microscopic world, and the beings by which it is peopled, than astronomers are with those remote systems of the universe which appear in the form of nebulæ and double stars. It was the improvement of the telescope alone which enabled Dr. Herschel to fix the views of astronomers upon those regions of space, to which, at a former period, their imaginations could scarcely extend; and, when the microscope shall have received a similar improvement, we may look for discoveries equally interesting, though less stupendous, even in those portions of space which are daily trampled under the foot of man.

It is both important and interesting to enquire into the cause of this limitation of microscopical discovery. The construction of single lenses, for the simplest form of the instrument, has been brought to great perfection. Dr. Brewster has in his possession glasses, executed by Mr. Shuttleworth, of the focal length of one-thirtieth, one-fortieth, and one-fiftieth of an inch, which are ground with great accuracy; and the performance of single lenses has been recently improved by Dr. Wollaston, who separates two hemispherical segments by means of a small plate of brass perforated in the centre. We cannot, therefore, expect any essential improvement in the single microscope, unless from the discovery of some transparent substance, which, like the diamond, combines a high refractive power with a low power of dispersion.

It is usual to say that the microscope magnifies objects seen through it; but this is true only with regard to the apparent, not the real magnitude of objects; they indeed appear to be larger with, than without the microscope, but in truth they are not; and the reason why they appear to be magnified will be easy to apprehend. by any person who understands the nature of the optic angle. The apparent magnitude of objects is measured by the angle which they are seen under by the eye; and those angles are reciprocally as the distances from the eye. If, therefore, at the distance of six inches, we can but just discern an object, and then, by interposing a lens, or other body, we can view that very object at a nearer distance, the object will appear to be as much larger through the lens than before, to the naked eye, as its distance from the lens is less than its distance from the eye. See OPTICS.

That this is the case, is evident from fig. 1, plate MICROSCOPE, where A is a point in an object not clearly visible to the naked eye, at a less distance than A B, because the rays which proceed from it are too divergent to admit of distinct vision till they have passed that distance; but if the same object be placed in the focus C of the lens D, fig. 2, the rays which proceed from it will become parallel, by passing through the said lens, and therefore the object is distinctly visible to the eye E, placed any where before the lens D. Consequently it will appear as much larger through the lens than to the naked eye, as C D is less than A B.

If an object, A B, fig. 3, be placed in one focus C, of a lens D E, and the eye in the other focus F, the eye will see just so much of the object as is equal to the diameter of the lens; for the rays A D and B E, which go from the object to the extremities of the lens D and E, and are united at the focus F, must necessarily proceed from the object to the lens parallel to the axis F C, and therefore parallel to each other; consequently the part of the object A B, seen by the rays D F, E F, will be equal to the diameter D E of the said lens.

If only the part *d e* of the lens be open, then only so much of the object *a b* as is equal thereto will be perceived by the eye. Now, since A B is equal to D E, or *a b* to *d e*, therefore the angle D F E, or *d* F *e*, is the optic angle under which the part of the object A B, or *a b*, appears to the eye at F; and, since G F is but one-half F C, therefore the angle D F E, or *d* F *e*, is double to that under which the part A B, or *a b*, would appear to the naked eye at the distance F C; that is, the eye sees the object, situate as above, twice as large with the lens as it would do without it.

If you would see a portion of an object larger than the lens, your eye must be placed nearer the lens than its focus. Let the lens be D E, fig. 4, its two foci F and C; in the focus C, let there be an object, A B, larger than the lens; suppose the rays A D, B E, proceed from the extremities of the object to those of the lens; it is evident from the figure they will be convergent, and therefore will, by the lens, be united in a point K, between the lens D E and its focus F: if then the eye be placed at K, it will take into its view an object greater than the lens D E.

Again, let G H be a portion of an object, A B, less than the lens D E; draw G D, H E, which will be diverging rays, and therefore will be united at a point I, farther distant from the lens than the focus F; hence, if an eye be placed farther from the lens than its focal distance, it can never see any object, or part of an object, at one view, so large as the lens, but always smaller.

And universally, the visible part of an object will be to the lens, as the focal distance of the lens to the distance of the eye.

Since then it is evident the nature of a convex lens is such as will render an object distinctly visible to the eye at the distance of its focus, the reason why they are used as microscopes is very plain. For suppose the distance A B, figs. 1 and 2, be six inches, where the naked eye B can but just perceive the object A distinctly, and let the focal distance C D of the lens D be half an inch; then, since C D is but one-twelfth of A B, the length of the object at C will appear twelve times as large as at A: if it were a surface, it would be 144 times as great, and the solidity or bulk would be magnified 1728 times.

If C D, the focal distance of the lens D, be but one-fourth part of an inch, then will that be but one-twenty-fourth of A B, equal six inches, and so the length of objects will be magnified twenty-four times, the surface 576 times, and the solidity 13,824 times; for those numbers are the square and cube of twenty-four. Whence it appears, that single glass lenses make very good microscopes, which have these advantages, that the object appears most clear, they occupy little room, are extremely portable, are procured at a small expense, and are more easily used.

Various methods have at different times been described, by means of which persons of ordinary ingenuity may construct for themselves single microscopes of a very high magnifying power, and possessing a very considerable degree of distinctness. The most common method is to take up with the point of a wetted wire several small fragments of crown glass, and to hold them in the flame of a candle till round globules are formed upon them. These globules, being carefully detached, are placed between two plates of lead, copper, or brass, the fractured part being carefully kept out of the field of view. The method recommended by Mr. Gray, of making microscopes of drops of water, can be considered in no other light than as an amusing experiment; and the single microscopes made by drops of transparent varnish, upon one or both sides of a plate of glass, and tried by Dr. Brewster, though they give excellent images, are still deficient both in portability and durability. The defect of the glass globules formed by the ordinary method is, that we cannot increase their diameter beyond a very small size; that it is difficult to give them a perfect figure; and that there is considerable trouble in fixing them in the brass or copper after they are made.

The following method, proposed and executed by Mr. Siveright, is free from the greater part of these defects, and will no doubt be considered as a valuable acquisition by those who either cannot afford to purchase expensive microscopes, or who are at such a distance from an optician that they cannot be supplied in any other way. Take a piece of platinum leaf, about the thickness of tinfoil, and make two or three circular holes in it, from one-twentieth to one-tenth of an inch in diameter, and at the distance of about half an inch from each other. In the holes put pieces of glass, which will stick in them without falling through, and which are thick enough to fill the apertures. When the glass is melted at the flame of a candle with the blow-pipe, it forms a lens which adheres strongly to the metal, and the lens is therefore set and formed at the same time. The pieces of glass used for this purpose should have no mark of a diamond or file upon them, as the mark always remains, however strongly they are heated with the blow-pipe.

The lenses which were made larger than one-tenth of an inch were not so good as the rest, and the best were even of a smaller size than one-tenth. As the lenses thus formed sometimes contain air bubbles, the best way is to make several, and select those which are freest from faults. An eye or loop, made by bending the extremity of a platinum wire, may be used instead of the platinum leaf. The reason for using platinum is, that the glass is more easily and perfectly melted in this than in other metals, which may perhaps arise from its being a bad conductor of heat, and from preserving its brightness. As platinum does not oxidate, the glass adheres better to the edges of the hole, and it may be used very thin, as it does not melt with the heat necessary for the complete fusion of the glass.

The first idea of *fluid microscopes* was suggested by Mr. Stephen Gray, who published an account of them in the Philosophical Transactions. They consisted merely of a drop of water, which was taken up on the point of a pin, and placed in a small hole one-thirtieth of an inch in diameter, in the middle of a spherical cavity about one-eighth of an inch broad, and a little deeper than half the thickness of the plate. On the opposite side of the plate was another spherical cavity, half as broad as the former, and so deep as to reduce the circumference of the small hole to a sharp edge. When the water is placed in these cavities, it will form a double convex lens with unequal convexities, which may be employed like any other single microscope in the examination of minute objects.

As water, however, has a considerable dispersive power, and a low power of refraction, fluid microscopes of a more perfect kind may be formed by using sulphuric acid, castor oil, oil of ambergris, or alcohol. The sulphuric acid has a very low dispersive power, and a greater refractive power than water, and will, therefore, make a more perfect lens than any other fluid body. Castor oil may be employed with almost equal advantage; and oil of ambergris and alcohol would answer the same purpose from their optical properties, though their volatility may render them less easily managed. The best method, however, of constructing fluid microscopes, is to take Canada balsam, balsam of capivi, or pure turpentine varnish, and let a drop of any of them fall upon a thin piece of parallel glass. The drop will form a plano-convex lens, and its focal length may be regulated by the quantity of fluid which is used. These fluid lenses are represented in fig. 5, as suspended upon the parallel glass; but the proper position is when the plate of glass is horizontal. If the lens is uppermost, the gravity of the fluid will make it more flat, and diminish its focal length. This, however, may be avoided, and the contrary effect produced, by inverting the piece of glass

If these lenses are preserved from dust, they will be as durable as those which are made of glass; and, when thick Canada balsam is used, the lenses will soon be indurated into a hard gummy substance, and resist any change of figure from the gravitation of their parts.

Ellis's single, or aquatic microscope is represented in fig. 6, where K is the box that contains the whole apparatus, which is generally made of fish-skin; on the top of the box there is a female screw for receiving the screw which is at the bottom of the brass pillar A, and which is to be screwed on the top of the box K. D, a brass pin, which fits into the pillar: on the top of the pin is a hollow socket to receive the arm which carries the magnifiers: the pin is to be moved up and down, in order to adjust the lenses to their focal or proper distances from the object.

In the representation of this microscope, the pin D is delineated as passing through a socket at one side of the pillar A: it is now usual to make it pass down a hole bored down the middle of the pillar. F, the box which carries the magnifying lens; it fits into the socket X, which is at the top of the pillar D. This arm may be moved backwards and forwards in the socket X, and sideways by the pin D, so that the magnifier, which is screwed into the ring at the end F of this box, may be easily made to traverse over any part of the object lying on the stage, or plate B. F is a polished silver speculum, with a magnifying lens placed at the centre thereof, which is perforated for this purpose. H, a brass semicircle which supports the mirror I; the pin R, affixed to the semicircle H, passes through the hole which is towards the bottom of the pillar A. B, the stage on which the objects are to be placed; it fits into a small dovetailed arm which is at the upper end of the pillar A. C, a plane glass, with a small piece of black silk stuck on it. This glass is fitted to a groove made in the stage B; a pair of nippers is fixed to the hole of the stage *a*, by the pin K; the steel wire of these nippers slides backwards and forwards in the socket; and this socket is moveable upwards and downwards, by means of the joint, so that the position of the object may be varied at pleasure. The object may be fixed in the nippers, or stuck on the point. To use this microscope, begin by screwing the pillar A to the cover; pass the pin R of the semicircle which carries the mirror through the hole that is near the bottom of the pillar A; push up the stage into the dovetail at B: slide the pin into the pillar; then pass the bar E through the socket X, which is at the top of the pin D, and screw one of the magnifying lenses into the ring at F. Now place the object either on the stage or in the nippers L, and in such a manner that it may be as nearly as possible over the centre of the stage; bring the speculum F over the part you mean to observe; then get as much light on the speculum as you can, by means of the mirror I. The light received on the speculum is reflected by it on the object. The distance of the lens F from the object is regulated by moving the pin D up and down until a distinct view of it be obtained. The rule usually observed is, to place the lens beyond its focal distance from the object, and then gradually slide it down until the object appear sharp and well defined. The adjustment of the lenses to their foci, and the distribution of the light on the object, are what require most attention. These microscopes are sometimes fitted up with a rack and pinion to the pillar A, and pin D, for the more ready adjustment of the glasses to their proper foci.

The form of a very convenient microscope is represented in fig. 7, where A B is a circular piece of wood, ivory, &c., in the middle of which is a small hole, one-twentieth of an inch in diameter; upon this hole is fixed, with a wire, a small lens C, whose focal distance is C D. At that distance is a pair of plyers D E, which may be adjusted by means of the sliding-screw, as in the figure, and opened by means of the two little studs *a e*; with these you take up any small object O, and view it with the eye placed in the other focus of the lens at F; and according to the focal length of the lens, the object O will appear more or less magnified, as represented at T M. If the focal length be half or one-fourth of an inch, the length, surface, and bulk, of an object, will be magnified as before described. This small instrument may be put into a case, and carried about in the pocket without any incumbrance. Those lenses whose focal lengths are three-tenths, four-tenths, and five-tenths of an inch, are the best for common use.

In the combination of single lenses to form the compound microscope, opticians have arrived at a great degree of perfection. The aberration of refrangibility can now be completely removed by a suitable arrangement of the individual lenses; and every artifice has been exhausted in suiting the apparatus to the various tastes of the purchasers, and to every purpose of popular observation. No attempt, however, appears to have been made by opticians to fit up the microscope as an instrument of discovery, to second the labors of the naturalist in preparing the subjects of his research, and to accommodate the instrument to that particular kind of preparation which is indispensably necessary for the preservation and inspection of minute objects.

In perusing the writings of those naturalists who have applied the microscope to the examination of minute objects, we find that the most difficult and perplexing part of their labor consisted in preserving and preparing the different insects and substances which they wished to inspect. Small insects instantly shrivel up, and lose their natural form as soon as they are killed, and the minute parts of plants suffer a similar change from exposure to the air. Hence Swammerdam and Lionet killed the insects which they meant to examine by suffocating them, either in water, spirit of turpentine, or diluted spirits of wine. The softness and transparency of their parts were thus preserved during the process of dissection, and, when they were completely developed, the insect was allowed to dry before it was presented to the microscope. Its parts were consequently contracted, and lost not only their proper shape, but that plumpness, and that freshness of color, which they possessed when alive.

In the preparation, indeed, of almost every object of natural history that is composed of minute and delicate parts, it must be pre-

served by immersion in a fluid; the dissection must often be performed in the same medium; it must be freed from all adhesive and extraneous substances, by maceration and ablution in water; and, when it has undergone these operations, it is in a state of perfection for the microscope. Every subsequent change which it undergoes is highly injurious; it shrivels and collapses by being dried, its natural polish and brilliancy are impaired; the minute parts, such as the horns and down adhere to one another; and the general form of the object, as well as the disposition of its individual parts, can no longer be distinctly seen. It is therefore a matter of considerable importance to be able to examine the object when wet, and before it has suffered any of these changes; and, by fitting up the microscope in the following manner, this may be effected without even exposing the object to the air.

The object-glass of the compound microscope should have the radius of the immersed surface about nine times the focal distance of the lens, and the side next the eye about three-fifths of the same distance. This lens should be fixed into its tube with a cement which will resist the action of water or spirits of wine; and the tube, or the part of it which holds the lens, should have an universal motion, so that the axis of the lens may coincide to the utmost exactness with the axis of the tubes which contain the other glasses.

Several small glass vessels must then be provided, having different depths, from one inch to three inches, and having their bottom composed of a flat piece of glass, for the purpose of admitting freely the reflected light which is intended to illuminate the object. The fluid in which the object has been preserved, or prepared, is next put into the vessel; and the object itself placed upon a glass stage, or, if necessary, fixed to it, is immersed in the fluid. The glass vessel is now laid upon the arm of the microscope, which usually holds the object, and the lens is brought into contact with the fluid in the vessel. The rays which divide from the object emerge directly from the fluid into the object-glass, and therefore suffer a less refraction than if it had been made from air; but the focal length of the lens is very little increased, on account of the great radius of its anterior surface. The object may now be observed with perfect distinctness; unaffected by any agitation of the fluid, its parts will be seen in their finest state of preservation; delicate muscular fibres, and the hairs and down upon insects, will be kept separate by the buoyancy of the fluid; and if the object, when alive, or in its most perfect state, had a smooth surface, its natural polish will not only be preserved but heightened by contact with the fluid. Aquatic plants and animals will thus be seen with unusual distinctness, and shells and unpolished minerals will have a brilliancy communicated to their surfaces which they could never have received from the hands of the lapidary. If the specific gravity of the substance under examimination should happen to be less than that of the fluid, and if it cannot easily be fixed to the glass stage, it may be kept from rising to the top by a piece of thin parallel glass, or by a small grating of silver wire stretched across the vessel.

In order to find the magnifying power of such a microscope, let $f =$ focal length of object-glass; $F =$ focal length of amplifying-glass; $d =$ distance of object from object-glass; $D =$ distance between the object-glass and the amplifying-glass; $m =$ magnifying power of the eye-glass; $M =$ magnifying power of the microscope. Then we shall find—

$$x = \frac{d f}{d - f} - D, \text{ and}$$

$$M = \frac{F}{x + F} \times \frac{f}{d - f} \times m$$

When the object-glass is equally convex, and when its anterior surface is immersed in water we shall have

$$x = \frac{1{\cdot}37 f d}{d - 1{\cdot}37 f}, \text{ and}$$

$$M = \frac{F}{x + F} \times \frac{1{\cdot}37 f}{d - 1{\cdot}37 f} \times m$$

When the object-glass is unequally convex, and a b are its radii, a being immersed in water, we shall have $f = \frac{5 a b}{2{\cdot}65 a + b}$; and, by using the value of f in the first equations, the magnifying power will be proved.

The method of fitting up and using the compound microscope, which has now been described, enables us, in a very simple manner, to render the object-glass perfectly achromatic without the assistance of any additional lens. The rays which proceed from the object immersed in the fluid will form an image of it nearly at the same distance behind the lens as if the object had been placed in air, and the rays transmitted through a plain concave lens of the fluid combined with the object-glass. If we, therefore, employ a fluid whose dispersive power exceeds that of the object-glass, and accommodate the radius of the anterior surface of that lens to the difference of their dispersive powers, the image will be formed perfectly free from any of the primary colors of the spectrum. The fluids most proper for this purpose are:—

Oil of cassia,	Oil of sassafras,
Oil of aniseseeds,	Oil of sweet fennel seeds
Oil of cummin,	Oil of spearmint,
Oil of cloves,	Oil of pimento.

These oils are arranged in the order of their dispersive powers; and, when those at the top of the list are used, the anterior surface of the object-glass will require a greater radius of curvature than when those at the bottom of the list are employed. Thus, in order to render the object-glass achromatic when it is made of crown glass, and when the fluid is oil of cassia, the radius of the anterior or immersed surface should be to that of the surface next the eye as 2·5 to 1. Lest these proportions should not exactly correct the chromatic aberration, it would be preferable to make the radii as 2·2 to 1, and then reduce the dispersive power of the oil of cassia by oil of olives, or any other less dispersive oil, till the correction of color is complete

If the oil of sweet fennel seeds is used, the radius of the anterior should be to that of the posterior surface as 0·8 to 1.

The *camera obscura* microscope is usually composed of a tube, a reflecting mirror, and a convex lens, in addition to the ordinary microscopic apparatus. The sun's rays being directed by the looking-glass through the tube upon the object, the image or picture is thrown distinctly and beautifully upon a screen of white paper, or a white linen sheet, placed at some distance to receive it, and considerably magnified. The apparatus for this purpose, as represented in fig. 8, is as follows: A, a square wooden frame, through which two long screws pass, and by means of two nuts, 1, 1, fasten it firmly to a window shutter, in which a hole is made for its reception, the two nuts being let into the shutter.

A circular hole is made in the middle of this frame to receive a piece of wood of a circular figure B. The edge projects a little beyond the frame, and contains a shallow groove furnished with a band, which, by twisting round and then crossing over a brass pulley 4, affords an easy motion for turning round the circular piece of wood B, with its connecting parts, to follow the course of the sun. C is a brass tube screwed into the middle of the circular piece of wood, forming a case for the uncovered brass tube D, which may be drawn backwards or forwards. E a smaller tube of about one inch in length, screwed to the end of the larger tube D.

In the large tube is a convex lens, whose focus is about twelve inches, designed to collect the sun's rays, and throw them more strongly upon the object. G a looking-glass of an oblong figure, set in a wooden frame, fastened by hinges to the circular piece of wood B, round which it revolves.

H a jointed wire passing through the wooden frame to enable the observer, by putting it backwards or forwards, to elevate or depress the glass, according to the sun's altitude.

When the microscope is employed the room must be rendered as dark as possible; for on the darkness of the room, and the brightness of the sun-rays, depend the sharpness and perfection of the image. Then, putting the looking-glass G through the hole in the window-shutter, the observer must fasten the square frame A to the said shutter by its two screws and nuts 1, 1; this done, adjust the looking-glass to the elevation and situation of the sun by means of the jointed wire H, together with the pulley and band.

As soon as this appears, screw the tube C into the brass collar provided for it in the middle of the woodwork, taking care not to alter the looking-glass; then, screwing the magnifier to be employed to the end of the microscope, take away the lens at the other end, and place a slider, containing the object to be examined, between the thin brass plates, as in the common microscope.

Things being thus prepared, screw the body of the microscope to the short brass tube E, and pull out the tube D, less or more, as the object is capable of enduring the sun's heat. Dead objects may be brought within about an inch of the focus of the convex lens; but the distance must be altered for living insects, or they will speedily be deprived of life. The short tube E, which the microscope is screwed to, enables the observer, by moving it backwards or forwards in the tube D, to bring the objects to their true focal distance, which will be known by the sharpness and clearness of their appearance; they may also be turned round by the same means without the effect being injured.

The solar microscope we have just been examining is calculated only to exhibit transparent objects, or at least such as permit a part of the incident light to pass through them; to view opaque objects another mirror must be used, in order that they may be seen by the light that they reflect.

In fig. 9 the mirror *a*, and the lens *c*, are the same as in the common solar microscope; but the converging rays from *c* are met by a mirror *e n*, placed diagonally, and which reflects the rays upon the opaque object S R; from the object they are reflected to the magnifier *o*, from which they proceed, diverging to the screen *p q*, where the object will be painted, and its apparent size increased.

Compound microscopes have been constructed of almost every possible dimension, from a few inches in length to that of twenty feet; but from practical experience it appears evident that, when their magnitude is augmented beyond a certain point, the performance of the instrument is deteriorated, though we suppose the amplifying power of both microscopes the same; indeed, those of the larger description, which have been made to examine objects of considerable dimensions, cannot be considered of any use except for amusement. The reason, however, why the smaller instrument produces a better representation of the object, has not been determined; for in both instruments (mathematically) the proportional errors are the same, but it may be that the errors in the smaller instrument, though existing, are not so divided as to be discoverable to the organ of vision. At present no certain proportion between the length of the body of the instrument and the focus of the object-glass has been determined, except that the body requires to be lengthened when the focal length of the object-glass is increased, to give its maximum effect. The average length of body for different object-glasses is from five to ten inches; for when the rays after once being acted upon are allowed to travel any considerable distance, to form the image in the focus of the eye-piece, they will be so much separated and weakened that the eye-piece will not be able to collect them truly. And it may be further remarked that the power should always be obtained by the object-glass in preference to the eye-piece; and, although it is well known that a flat and more extended field is obtained by the latter, yet when these are procured no distinct idea of the structure of the object is discoverable, and thus the very intention of the microscope is destroyed, which ought to unfold to our perception the nature and functions of bodies too minute for ordinary inspection.

Some time ago an eminent natural philoso-

pher, professor Amici of Modena, constructed a very excellent catoptrical microscope, in which he seems to have avoided the imperfections to which the instruments formerly constructed upon the same principle were liable, and to have combined several advantages which are not possessed by the best dioptrical microscopes now in use. The ingenious inventor has published a minute description of this improved instrument, in a memoir inserted in the eighteenth volume of the Transactions of the Italian Society. The body of this microscope consists of a horizontal brass tube, twelve inches in length, and one inch and one-tenth in diameter. At one end of the tube is placed a concave speculum of metal, whose axis coincides with that of the tube, and whose superficies is elliptical; and so calculated, that of the two foci, the one falls at the distance of two inches and six-tenths, and the other at twelve inches from its centre. A small arm within the tube carries a small plain mirror of metal of an oval form, placed at the distance of one inch and six-tenths from the former, opposite to it in an oblique direction, and supported by an oblique section of a metal cylinder five-tenths of an inch in diameter. The centre of the polished surface of this mirror coincides with the axis of the concave mirror, which is situated at the distance of one inch and five-tenths from the centre of the other.

This plain mirror is so placed that, while it receives the image of the object (which is placed on a moveable object-bearer attached to the pillar below it), by means of a small aperture in the under part of the body of the tube, it throws it towards the concave mirror, in which it may be examined by the eye of the observer, applied to the opposite end of the tube, through a greater or smaller number of magnifying eye-glasses, which may be fitted to it.

The internal diameter of the tube, which regulates that of the large mirror, may be one inch and one-tenth, and the thickness of the surrounding metal about one-twentieth of an inch. Upon this construction, the object to be examined may always be at the distance of half an inch from the edge of the tube, and consequently be very well lighted on every side,—transparent objects from below, by means of a common illuminating mirror, fitted to the pillar, and moveable,—and opaque bodies from above, either by the natural light falling directly in, or by concentrating an artificial light, by means of a convex glass fitted to the object-bearer—or, still better, by means of a pierced mirror of metal, which is fitted to the tube below, over the object, so as to be brought more or less near to it. The large illuminating mirror below should be concave, having a diameter of three inches, and a focal distance of 2·5 at the utmost.

The effects of the two last mentioned mirrors may be reciprocally combined, by means of a common corresponding adaptation,—by receiving and reflecting the rays of light so as to produce the highest degree of intensity of light, and the most perfect illumination of the object on all sides, both as a whole, and in its different parts, an advantage indeed, which may be obtained in dioptrical instruments by similar means.

The inventor considers the proportions above given as best adapted for the convenient use of the instrument, in order to preserve, along with a high degree of effect, and even the highest degree of magnifying power, a moderate distance of the object from the microscope, viz. half an inch, which not only allows the most simple and perfect illumination from above, but also admits of our examining objects of considerable size entire, without separating the parts, and also small animals alive.

A common dioptrical microscope, whose object-glass has a focal distance of six lines, would correspond with this state of the object, and consequently admit of similar advantages, but with a much diminished magnifying power, of about 1500 or 2000 in the area. Professor Amici has accordingly compared the best English microscopes of Adams and Dollond with his own; and, upon a comparative examination of the same objects, he maintains that his instrument shows the object more clearly and distinctly, even when magnified in the same degree. The professor had no opportunity of making experiments with the microscope of De la Barre, and those made at Benedictbeuern by Utzschneider and Fraunhofer; but he thinks himself justified in concluding that his own admits of a far greater degree of magnifying power than the latter, as he perceives that their largest microscope does not magnify the objects above 22,500 times in the area, while his goes the length of 1,000,000. He has also endeavoured to show, by a mathematical calculation, that such a high degree of magnifying power cannot be attained in a dioptrical instrument.

The following, according to Amici, are the advantages of his microscope; 1. The observer has the convenience of being able to examine the object in a horizontal position, while, in those constructed on the dioptrical principle, the object is examined in a vertical position, that is from above. The observer, therefore, may be seated, has no occasion to bend his head, and can examine objects more conveniently, or for a longer time than with a large dioptrical instrument on the common construction. 2. The different degrees of magnifying power can be easily and speedily applied and changed, nothing more being necessary for this purpose than to change the eye-glass, without varying the position or distance of the object, so that it may be examined with great rapidity in all different degrees of magnitude, without the least variation of the points of view; while, in the dioptrical instruments, it is necessary not only to change the object-glass, but also the visual distance, which not only occasions loss of time, but very seldom admits of the object being again seen in the same position, and in the same point of view. 3. As in this new instrument the object always remains in the same position, and is kept constantly at the distance of half an inch from the body of the microscope, it consequently admits of our examining objects immersed in fluids, and animals swimming, and that nearly at an equal depth, and in every degree of magnitude. With dioptrical instruments, on the other hand, this is quite impossible, on account of the

shortness of the focal distance in the highest degrees of magnifying power, as the object-lens must be brought so near the object as almost to come in contact with the fluid. 4. The light may be brought to bear upon all sides and in all directions, even by means of a lamp or taper, as the flame can be brought very near the illuminating mirror, without being troublesome to the observer. 5. As metallic specula do not disperse the light, and consequently produce no colors, the objects appear of their natural color. 6. The diameter of the concave mirror being so large, compared with its focal distance, we may expect so much more distinctness. 7. As the distinctness of the image produced by reflection is greater than that produced by refraction, the degree of magnifying power may be carried much higher.

While speaking of the compound microscope, it may be proper to state that the most valuable object-glasses for this species of instrument are those that are rendered achromatic; as a much larger angle of aperture may thus be obtained than by the ordinary arrangement. These were first constructed at the suggestion and expense of Dr. Goring, by Mr. W. Tully, in the summer of 1824, and more recently in France, by M. Chevalier. The aplanatic of Mr. Tully consists of a concave of Guinard's flint glass placed between two convex lenses of crown and Dutch plate glass. The apertures obtained in these object-glasses are equal to half their focal distances, which are from 0·2 to 1·0 inch focus. By the increase of aperture which is here attainable the penetrating power is augmented, so that the varied markings on objects are rendered visible with these large apertures, which with common object-glasses of the same power are wholly undiscernible. This property of the penetration of a microscope being always as the angle of aperture, was first pointed out by Dr. Goring, and is fully borne out by experiment. In the telescope the penetrating power necessary to observe stars and nebula is dependent on the area of the object-glass or metal, without relation to its focal distance; but in the microscope it is the result of the aperture in proportion to their focal distance. The difficulties that present themselves in correcting the aberrations of these object-glasses, when of short focus, is considerably increased, though their penetrating powers are always improved by a diminution of their focal length. The spherical aberration is greater and more difficult to correct than in telescopes (the convex seldom having sufficient abberration to correct the concave); and, as the rays enter diverging from the object, the calculations of their radii are more abstruse than in a telescope for parallel rays. The curvatures and dimensions of one of Mr. Tully's object-glasses are as follows:—

	Inch.
Sidereal focus of the object-glass	0·933
Total diameter of the lenses	0·55
Clear aperture	0.5

		Inch.	
Radius of	1st surface	0·825	convex
Ditto	2nd	0·525	crown
Radius of	3rd surface	0·5	concave
Ditto	4th	0·5	flint.
Ditto	5th	0·575	convex
Ditto	6th	0·575	Dutch plate.

	Inch.
Specific gravity of crown	2·527
Thickness of ditto	0·15
Specific gravity of flint	3·627
Thickness of ditto	0·164
Specific gravity of Dutch	2·519
Thickness of ditto	0·175

The object-glasses of M. V. Chevalier are constructed on the principles laid down by Euler, and consist of a double and equally convex lens of plate glass cemented to a plano-convex of Guinard's flint. The construction is remarkably simple, the radii of all their surfaces being alike. The measures of one of these achromatics obtained by Mr. Lister are as follows:—

	Inch.
Radii of the isosceles convex	0·66
Radius of the plano-concave flint	0·66
Thickness of the concave at the edge	0·74
Thickness of the convex at the centre	0·72
Diameter of the lenses	0·36

When these object-glasses came first into this country, although achromatic, and two of them were combined, which is a considerable improvement on the single ones, they could not show the test objects, the aperture being cut off by a small stop; but on removing this stop Dr. Goring was enabled to make them effective on most of them.

The combination of three sets of achromatic lenses for an object-glass has recently been executed by professor Amici, who, in order to have the body of the microscope horizontal and object-glasses vertical, introduces a right-angular prism to change the direction of the rays. But the introduction of so many surfaces, viz. fifteen, has a tendency to weaken the outline of the objects. Mr. Dollond has, however, lately combined two triple object-glasses of one inch focus, and about half an inch aperture, which perform extremely well: they can also be used separately. It is necessary for us to remark here that, as the ray after passing through the first aplanatic combination is in a different state to what it is on entering the second, due correction ought to be made when these glasses are intended to be used separately and combined; indeed, in those of short focus, such correction is absolutely requisite; so that, if they are perfect when combined, only one can be so if employed singly. When a triple one and a double one are combined, the performance seems best of all.

If we are desirous of producing an aplanatic object-glass, without using the achromatic combinations above described, that of Mr. Herschel will be found of great value, as it is free from all spherical aberration in the axis. One has been executed of only one-sixth of an inch focus, with an aperture of the one-fifteenth of an inch, which brings out all the test objects and exhibits opaque ones with facility. This combination is made of crown glass.

MIDDLE AGES. That portion of duration is called the middle ages, in the history of Europe, which begins with the final destruction of the Roman empire, and ends with the Reformation; or with the discovery of America; or with the taking of Constantinople; or with the invention of the art of printing: the propriety of selection being regulated by the object of each historian. In general, the middle ages may be said to embrace that space of history in which the feudal system was established down to the most prominent events which led to its overthrow; although its consequences and influence are still observable in the states of Europe. The dark ages mean the first centuries of the middle ages, a name which they certainly deserve; still, however, the destruction of the Roman institutions, by the irruption of barbarous tribes, is often unduly lamented, and the beneficial consequences attending it overlooked. It is certainly to be regretted that acquisitions, which cost mankind ages of labour, were lost in the general wreck, and only regained by the efforts of many successive generations; the flowers of civilization trampled under foot by barbarian warriors; and those nations to which Roman civilization extended, previous to the great Teutonic invasion, thrown back into primæval barbarism.

The feudal system filled Europe with powerful barons, possessing vast landed estates, and commanding the services of numerous armed adherents. Proprietors of the soil, with arms perpetually in their hands, they were too proud to obey any laws but those of honour, which they had themselves enacted, and despised all engaged in peaceful occupations, as ignoble and created to obey. In this state of society the classes, not military, preserved their independence by union, which afforded them mutual protection, enabled them to exercise their callings unmolested, and thereby acquire wealth, which served as a counterpoise to the landed possessions of the barons: this necessity led to the foundation of cities. These small states gradually grew up into great ones; and many citizens acknowledged no superior, except the highest authority of the nation to which they belonged. Strong walls, in conjunction with the valour of the townsmen, secured the freedom of those that dwelt within, and protected them from the tyrants of the land; well ordered civil institutions preserved peace and prosperity within; and both were secured by the wealth acquired by trade and manufacturing industry. The barons endeavoured to retain their hold over the citizens, by establishing themselves within the walls, and expressing an ambition to become chief magistrates of these little commonwealths. In some instances they soon usurped the exclusive power, by flattery and apparent condescension; while in those states that were imperfectly organized, and where the pride of the nobles was excessive, the power and prosperity of the cities rose to such an height, that in Germany and Italy they became formidable even to the emperor; and the people, a third estate, was fully developed in Arragon as early as the twelfth century.

The third estate, the cities, united with the barons in wresting the magna charta from king John of England, in 1215; and their growth in France may be traced to the conduct of Louis Le Gros, and his successors, particularly Philip the Fair, 200 years after him, who deemed it their wisest policy to protect them against the nobility, and thereby increase their own ability of resisting that powerful order. Cities acquired the earliest and the greatest pre-eminence in Germany and Italy: what could not be accomplished by single towns in France and England, was effected by the unions or leagues of several in the great empire; the league of the Lombard cities in Italy; the Hanseatic, Rhenish, and Suabian leagues in Germany, appeared at the same time as great and formidable powers. Under the protection of such associations, and sheltered by embattled walls, all arts and trades, and every species of civilization, made rapid progress. Many important inventions originated amongst the citizens of those free states, or were suggested by their active, commercial, and manufacturing spirit.

It is remarkable that the ancient and modern republics were equally exposed to the overwhelming power of ambitious individuals, so dangerous to all free communities: the oppressed portion of the citizens were again compelled to have recourse to the same means of relief that had originally given rise to the parent city, and generally bound themselves to each other by some formal contract, for the better protection of their rights. From such associations, usually formed amongst those of the same trade, and having for their object, next to security from external enemies the maintenance of internal order in those stormy periods, arose corporations or guilds, which were under the direction of a master. At first none were admissible into these bodies who had not served an apprenticeship to some particular trade: at a later period admission was purchased by individuals who wished to share in the advantages of the association; this was frequently the case in the 14th century, when the corporations obtained almost exclusive possession of the government of the cities; the corporations taught the nobles that, as they contributed nothing to the prosperity of the place, by their industry, it did not become them to govern it. As long as the nobility continued in the cities, after this exclusion from power, they preserved themselves in close connexion, and with those in the country formed confederacies against the corporate power. Associations, the only means of security against the disorders of the time, became so universal, that every where persons of the same trade or profession were closely united, and had certain laws and regulations amongst themselves: even knowledge, in the universities that were established, was obliged to do homage to the spirit of the age, and the liberal arts themselves, in the latter part of the middle ages, were fettered by the restraints of corporate rules.

The most remarkable and characteristic institution of the middle ages was chivalry. The profession of the nobles was war; no one of their order, who had not served as a knight, could bear a lance or command a troop of cavalry; and the service of years, as an attendant or

squire, was necessary to entitle even one of the highest order to be dubbed a knight; but squire, knight, and baron, were all inspired with the same romantic spirit of honour, gallantry, and devotion. The religious zeal of the middle ages induced hundreds of youths, of both sexes, in the bloom of life, to shut themselves up within the gloomy walls of a cloister, or retire to wild deserts, and there pass their lives in penitence and prayer; thousands of bare-footed pilgrims annually travelled across sea and land, to pray and do penance at the tomb of the Saviour; hundreds of thousands flocked thither also, with the cross in one hand and the sword in the other, to free the Holy Land from the pollution of infidels. The artful and ambitious, taking advantage of this enthusiastic spirit, established by its means intolerance, the destruction of the Jews and heretics, the splendour of the papal court, and the all-embracing system of the hierarchy. In opposition to the secular, which rested on the feudal system, and was sustained only by armies of vassals, the pope formed, from archbishops, bishops, priests, still more from the generals of religious orders, provincials, abbots, and monks, an immense army, invincible through its power over the conscience, and through the spiritual weapons which belonged to it and to its head.

All the kings of the West acknowledged the pope to be the living vicegerent of Christ: many were his vassals, many tributary; almost all obedient and subject to him, and in a short time victims of a vain resistance.

Arnold of Brescia, the Waldenses, Wickliffe and Hus, and their followers, endeavoured to overthrow the corrupt hierarchy by reminding the people of the simplicity and poverty of the primitive church; they found, unhappily, that their contemporaries were not yet ripe for freedom of mind, and their noble efforts, consequently, in a great measure failed. Mendicant orders of friars, and the institution of the inquisition, obstructed the dawning light of the 13th century: excommunications and interdicts held all Christendom in terror; till at length, with the diffusion of a free spirit of investigation, the establishment of more rational order amongst monarchies, and the cooling of religious enthusiasm, the veil of darkness was drawn aside, the close of the middle ages approached, and Luther arose, to free the mind from bondage.

Poetry was revived, and much cultivated, in those ages. The chivalrous knights of those times were passing their lives in battle, in romantic deeds, in festive pomps, and religious exercises. Poetry first appeared amongst the knights during the 12th century, in the southern provinces of France; there chivalry first sprang up, and with it shot forth the first sparks of modern poesy. The founders of modern poetry were provincial Troubadours, who sung at the court of Brerengarious of Toulouse: soon after these the French trouveres, and the German minnesingers, poured out their lays in their mother tongue: the Italians, mistrusting their own, sang in the Provençal; and the English, from a similar apprehension, in the French tongue. The Italians are indebted for their high poetic fame to Dante, who brought the Tuscan dialect into honour, and enabled the minstrels to establish a national poetry. In Spain the Catalonian poetry was the same as the Provençal, but the Castilian and Portuguese partook more of the Arabians. The modern epic is distinguished from the poetic narration of the ancients, by its majestic tone, its indefinite longing for something more elevated than the realities of earth, which have conferred upon it the title of romantic.

The subjects of the romantic epics are limited to three cycles or collections of stories: the first of these is the truly German, Nibelungen, the stories of Attila, and the heroes of the time of the general migration of nations; next to these rank the equally old tales of the British king Arthur, his round table, and the Sangraal, which, according to the old Welsh fables, was sung in France, and afterwards in Germany, and to which Tristan, the enchanter Merlyn, and others belong: to these a third collection is to be added, originally French, of Charlemagne and his peers, of Roland, the enchanter Malegys, and the four sons of Harymon: as to the famous romance of Amadis de Gaul, this belongs peculiarly to the Spanish, and not to one of the three collections here mentioned.

Historic events of ancient and modern times, particularly the exploits of Alexander the Great, the Crusades, Scripture History, and the incidents of the ancient epics of Homer and Virgil, furnished subjects for poetical works towards the close of the middle ages. Poetry gradually declined in the two last centuries of those ages. In the thirteenth century there was not a story in the three cycles, before mentioned, that was not eagerly sung by many poets, and upwards of 1400 songs, written by 136 poets of this century, are contained in the Manesse collection alone: the voice of the minstrel was almost wholly silent in Germany, France, and Spain, in the fourteenth century; but Italy boasted of her Petrarch and Boccacio, and England of her Chaucer: after the 14th century, hardly a single poet appeared amongst the knights. Epic poetry was replaced by romances in prose; and the lyric poetry of France and Germany fell into the hands of the Master-singers, who, by a studied observance of rules, preserved its formal existence: so did it continue until the 15th century, when all were attentive only to the great events that were in preparation, and actuated by a spirit of thinking, were far removed from that free flow of feeling which had given birth to the poetry of the past time. Ariosto, the Italian Homer, flourished at the close of the middle ages, when the early spirit of poetry lived only in remembrance. A new national poetry was introduced in England by Shakspeare, and in Spain by Cervantes.

Architecture and painting attained the highest excellence: the noblest buildings of the ages that had long preceded, appeared only as the ornamented forms of habitations which necessity had created, and can at most be called fine buildings; but the Gothic or pointed architecture of the middle ages was founded on a great conception; this conception, which appears in the union of the grandeur of great masses with the

finished delicacy of parts, was the sylvan temple of the first inhabitants, was the representation of the world. Painting and other arts came from Greece, in the 14th and 15th centuries, into the Western kingdoms, and attained their greatest splendour in the middle ages, upon the Lower Rhine and in Italy.

Scientific learning at that period was almost wholly neglected. Charlemagne encouraged the growth of science, and endeavoured to instruct the people, but his exertions hardly produced any effect beyond his life; and even some centuries after his reign the German tribes considered no knowledge of advantage, but that of managing the lance and steed. In those days the most distinguished could scarcely read or write, and whoever obtained further learning, particularly in mathematics or national science, exposed himself to the hazard of being burned as a sorcerer. The learning of the ancients was preserved through those ages, and handed down to us by the monks, who were educated in the monastic schools, and whose natural occupation was literature. They copied old writers, particularly the fathers of the church, registered passing events in chronicles, and succeeding ages are indebted to them for the preservation of the valuable remains of antiquity, for the materials and stimulants to new improvements.

In the history of the Eastern empire the introduction of Mohammedanism and the Arabic literature is analogous to the middle ages of the West, in marking epochs in their history. In the 11th century a partial taste for literature was given by the monks, and afterwards by the arts and industry that prevailed in the cities: learning was encouraged by Henry II. of England, by the Hohenstaufen, St. Louis, the Alphonsos, and other intellectual princes: and from these times, the age of Lanfranc, Abelard, and John of Salisbury, the middle ages produced distinguished men, whom the coldness of their contemporaries, in the cause of science, only urged to a more ardent pursuit of it.

Dialectics, from whence the church dogmatics were formed, were much cultivated; a disputatious spirit awoke, that was not calmed until the theses of Luther in Wirtemberg shed a new light upon science. The Reformation was the cause and origin of high intellectual exertion and freedom of thought, and materially assisted the striving after freedom of conscience, which originated some centuries before, with the flight of the Greek scholars from Constantinople; and both were aided in their operation by the invention of printing, which had been encouraged by the princes of Italy, and had shone forth in Germany, in the brotherhood of Deventer, in Wessel, Erasmus, Celtes, Reuchlin, and others: with the appearance of these men, with the rise of the sun of the new day, the romantic twilight of the middle ages faded.

MIDAS, in fabulous history, the son of Gordius by the goddess Cybele, a king of Phrygia.

Midas, in zoology, the ear shell, the smooth ovato-oblong buccinum, with an oblong and very narrow mouth. It consists of six volutions, but the lower one alone makes up almost the whole shell.

MIDDLEBURG, a considerable and well-built town of the Netherlands, on the island of Walcherin, forty-six miles south-west of Rotterdam.

MIDDLEBURY is a post town, and the capital of Addison county, states of Vermont, United States, standing on both sides of Otter Creek; eleven miles south-east of Vergennes, thirty-one south of Burlington, thirty-two north of Rutland, and fifty-one south-west of Montpelier.

MIDDLEBOROUGH, a post town of Plymouth county, Massachusetts; is ten miles west of Plymouth, and thirty-nine south of Boston, United States. Population 4400. This is a large township, and contains a rolling and slitting mill, a shovel manufactory, two forges, two furnaces, two cotton manufactories, a town-house, an academy, and eight houses of public worship, three for Congregationalists, and five for Baptists.

MIDDLESEX, an inland county, containing the capital of England, obviously derives its name from its situation, being inhabited by the Middle Saxons. Prior to the Roman invasion it was inhabited by the Trinobantes. After the complete subjugation of the island this district was made part of the division named Flavia Cæsariensis. Middlesex is situated towards the south-east part of the island, and bounded on the south by Surrey, from which it is divided by an imaginary line down the middle of the river Thames; on the east by Essex, from which it is divided by a similar line drawn along the middle of the river Lea; on the west by Buckinghamshire, from which it is divided by a supposed line drawn down the middle of the Coln; and on the north by Hertfordshire, from which county it is divided by an irregular line of parish boundaries. This county is of a very irregular shape; but if its shape were reduced to a parallelogram, of equal superficies, the medium length and width would be about twenty miles by fourteen; and consequently it contains 280 square miles, or 179,200 acres. It is in the province of Canterbury, and diocese of London. It is divided into Edmonton hundred, Elthorne hundred, Ossulston hundred, Finsbury division, Gore hundred, Holborn division, Isleworth hundred, Kensington division, Spelthorn hundred, Tower division, the city of London within the walls, and the city and liberties of Westminster. These are subdivided into 230 parishes, precincts, and extra-parochial places, whereof 122 are within the city of London, ten in the city and liberties of Westminster, and ninety-eight in the rest of the county. Here are also two cities, and seven market-towns.

Of the climate of this county, Mr. Middleton, in his Agricultural Report, observes that the temperature of the atmosphere, except, perhaps, so far as the influence of London fires extend, is nearly the same through the whole county; there being no situation so much elevated as to produce the cold and thin air that we find in mountainous countries. In general it is healthy, owing to the greater part of the soil being naturally dry; and the more moist situations, being well-drained, are consequently free from those unhealthy vapours which usually arise from stagnant waters. The fires of London, in which are

consumed upwards of 800,000 chaldrons of coals annually, have a sensible effect on the climate in its neighbourhood, by drying and warming the atmospherical air; which, being thus rarefied by heat, constantly passes upwards, and makes way for a fresh supply to come in from every side. The most stationary winds are from the south-west and north-east. All others are variable and unsettled. Those from the south-west are supposed to blow six-twelfths of the year, and those from the north-east about five-twelfths. The varying winds blow from all the other points of the compass about the other one-twelfth. The winds seldom blow with so much force in this district as to shake the grain out of the ripe ears of the standing corn. The greatest falls of rain come from a few points west of the south, and are of the longest continuance when the wind has passed through the west to the south. In the spring months the damp on low ground is sometimes congealed by cold, when there is no such appearance on the hills; and thereby some of the young shoots of the most tender shrubs and plants are destroyed in the former situation, when no injury happens to those in the latter. This phenomenon probably happens less frequently in Middlesex than in such counties as abound more with hill and dale. The extremes of heat and cold are often very great. The thermometer has been known to rise as high as 84°, and to fall as low as 6° below 0°: these extremes, however, fortunately, never last long. Dr. Fordyce says that the heat of the air in London is very variable, seldom remaining equal for many days; and every year differing entirely from the preceding ones, not only in heat, but also in moisture and rains. Sometimes the winter is severely cold, with frost from November till May. In the month of February, 1814, the writer of this sketch, with many thousands besides, walked along the river Thames, from Blackfriars Bridge to nearly London Bridge, so firmly rivetted was the ice at that time. A second or third 'Thames Fair' was held on the ice, which lasted many days. This, however, is a very unusual circumstance. Sometimes, however, the water in this county is not frozen for more than ten or twelve days. Most commonly there is a little frost in November and December; but otherwise these months are usually very foggy and moist. The principal frost generally is in January; February is commonly a mild, open, and moist month; March is generally cold and dry. The summer months vary as much: sometimes there are three months very warm; sometimes not more than a week; the latter half of July is commonly the hottest. In August heavy rains often fall, especially in the last half of the month. The most common summer heat is from 65° to 75°. The most common winter heat, when it freezes, is between 20° and 30°; the most frequent, when it does not freeze, between 40° and 50°. These observations respecting the climate should be understood to refer more particularly to the cities of London and Westminster.

The soil of this county varies extremely, from the operation of the elements, from its being more or less manured, and from cultivation; so that the surface of all the lands assumes more or less the appearance of loam. Accordingly a surface of perfect sand, clean gravel, or pure clay, is not now to be found in any part of the county. The following account of the soil and fertility of Middlesex, extracted from Norden's Speculum Britanniæ (written in the reign of Queen Elizabeth), may amuse the reader who wishes to compare ancient with modern times:—'The soil of Middlesex is excellent, fat, and fertile, and full of profite; it yeeldeth corne and graine not onlie in abundance, but most excellent good wheate, especially about Heston, which place may be called Granarium tritici regalis, for the singularitie of the corne. The vaine of this especiall corne seemeth to extend from Heston to Harrow-on-the-Hill, between which, as in the midway, is Perivale, more truely Purivale, &c., &c. Yet doth not this so fruitfull soyle yeeld comforte to the wayfaring man in the winter time, by reason of the claieish nature, which, after it hath tasted the autumne showers, waxeth both dyrtie and deep; but unto the countrie swaine it is a sweet and pleasant garden, in regard to his hope of future profite, for

The deep and dirtie loathsome soyle
Yields golden graine to painful toyle.

The industrious and painful husbandman will refuse a pallace to droyle in these golden puddles.' 'The wheat of Heston was so famous that Queen Elizabeth, as it is reported, had the most part of her provisions from that place, for manchet for her Highnesse's own diet.' The summits of most of the highest hills in the county consist of sand and gravel, though frequently intermixed with loam. Hampstead Hill consists of eight or ten feet of yellow iron-stained sand, with some loam or rounded flints, on a pure white sand of many more feet. The surface is covered with furze, except where the ground is dug. Loamy sand, or turnip and barley land, includes all that portion of country lying between the road leading from Hounslow to Colnbrook on the north, and the river Thames on the south, containing in depth from one foot to three (though for the most part from eighteen inches to two feet), on the gravel of small flints, six, eight, or ten feet in thickness; and under the gravel is a leaden-colored tenacious earth, used by the tile-makers, of great depth. On the east side of the county, the whole way from Tottenham to Enfield Wash, the superstratum is of the same light nature, of from six inches to two feet in depth, on a gravel of small flints, which can only be dug, for the repairing of roads, to the depth of from two feet to five, owing to its then putting on the appearance of a quicksand, so filled with water as to prevent all deeper digging. Sandy loam will include all the land between the Colnbrook and Uxbridge roads, on the west side of Hanwell and Hounslow, of from eighteen inches to upwards of five feet in depth, on six or eight feet of the gravel of flints, on a subsoil of impervious leadened-colored earth. Of this description is the south side of the parish of Harefield, and the parishes of Twickenham, Isleworth, Ealing, Chiswick (the soil of which is from a strong to a tender or sandy loam, and from a rich and fertile to a white and sharp sand and gravel), Kensington, Fulham (consisting of a light, black, and fertile soil), Brompton, and Chelsea. Strong

loam: all the land from Ryslip and Ickenham on the west, to Greenford, Apperton, and Harrow, on the east, is composed of strong loam. The land about South Mimms is also of this kind. The level between Islington, Hampstead, and Hornsey, is a strong but very productive loam. Loamy clay, which is generally called clay, as is the leaden-colored impervious subsoil before repeatedly mentioned, constitutes the north aspect of a hill between Uxbridge Common and Harefield, the land north-west of Ryslip, the greater part of Hanger Hill, a wood near the east end of Hillington Heath, and the land between the river Brent and Hampstead, on the Hendon road. The meadows on the north-west side of Hendon church, towards Page Street, are of nearly the like kind; much of this parish, indeed, is of a clayey nature, yet there are patches of sand, and more of gravel. From Nightingale Hall by Colney Hatch to Whetstone the land is of a loamy clay, mixed with pebbles of flints; and from Potter's Bar, for about two miles towards South Mimms, the soil is the same. The north side of Highwood Hill has a thin skin of loamy clay, on a subsoil of yellow clay; and in many of these places the subsoil is a yellow clay; but all the varieties abound with rounded flints. Peat: The moors near the river Coln, the whole distance from Rickmansworth to Staines, consists principally of peat on a substratum of the gravel of flints, which occasionally in almost every place about here shows itself on the surface. Peat has also been found on the borders of the river Lea, and in the Isle of Dogs. This isle which contains nearly 1000 acres, most or all of the land on the flat borders of the rivers Lea and Coln, some inconsiderable quantity of land on the side of the Brent, the small islands in the river Thames, and many pieces of land situated in the various nooks and windings of that river, come under the description of marsh land. The surface of this county, though 'gently waving,' can no where make pretensions to what is called the picturesque.

No ragged woody mountains nor craggy ivy-bound rocks here present themselves to intercept the traveller on his way, or to captivate the fancy of the painter; but the more chaste, beautiful, and ornamented scenes may be found in many parts of the county. The inequalities of the surface which we meet with in this district contribute to health, ornament, and beauty. Here are not many dingy heaths nor sombre-colored woods to offend the sight in the gay season of May; but shady groves, diversified plantations, and meandering rivers. Numerous villas, ornamented grounds, lawns, and medallions of beautifully flowering shrubs almost every where present themselves to the view of the traveller; which, together with the great number of lofty spires and gay carriages, cannot fail to remind him of being in the vicinity of a metropolis which may very justly be called the Centre of Commerce, Wealth, and Fashion. The north border of the county is high ground; and, by the shelter it affords, adds considerably to the fruitfulness of the other parts. The principal hills are Highwood and Hendon, the hill at Barnet, another between that place and Elstree, also Brockley Hill; which, together with the Highgate and Hampstead hills, are the highest in the county. Their summits are nearly of the same level, which is about 400 feet above the level of the tide. Mr. Middleton is of opinion that Hampstead is a little higher than Highgate; and as it is considerably higher than Harrow, and most other ground in the county, he estimates its apparent height in the following manner: viz. as near as can be judged by the eye, it is a small matter higher than the top of St. Paul's cross; therefore, suppose St. Paul's church-yard to be above the tide thirty feet; the height of St. Paul's is said to be 340 feet; and this writer thinks Hampstead is higher by about thirty feet: which several dimensions make Hampstead to be above the level of the tide 400 feet, as above stated. From Norwood to Cowley, for a length of six miles on the Uxbridge Canal, the surface is eighty-five feet above low-water mark at Brentford Bridge; at Uxbridge it is ninety-six feet; and in the meadows near Harefield it is 107 feet above the said mark. All the land to the south of the road, passing from Brentford through Hounslow to Longford, is so nearly level as to have no more than a proper drainage, and much the greater part of it is less than ten feet above the surface of the river Thames at Staines Bridge, and not more than from three to five feet above the level of the rivulets flowing through this district. From Staines, through Ashford and Hanworth Common to Twickenham, a distance of seven miles and a half, is a perfect level, and generally from ten to twenty feet above the surface of the river Thames. Round the one mile-stone on the Kingsland Road, the surface is lowered from four to ten feet (average five), by the earth having been dug and manufactured into bricks, over an extent of more than 1,000 acres. The recent works on Highgate Hill, now forming one of the noblest roads in the kingdom, and called the Highgate Tunnel, or Archway, have lowered the hill many yards, though they have no sensible effect on the general face of this part of the county.

Middlesex is abundantly supplied with very excellent water. The Thames, the prince of rivers, divides this country from Surrey. The largest ships in the service of the East India Company can safely come up this river, to the edge of the county at Blackwall. It is navigable for West India ships to London Bridge, and for barges all along the southern border of the county. This river is rendered famous by the port of London in every commercial part of the world. The tide flows for about twenty-three miles up the Thames, along the side of the county. This river, from Oxford to Maidenhead, falls about twenty-four feet every ten miles; from Maidenhead to Chertsey Bridge nineteen feet every ten miles; from Chertsey Bridge to Mortlake thirteen feet every ten miles; and thence to London one foot per mile; and the fall gradually diminishes till it is lost as the river approaches the sea. To this noble and capacious river the county of Middlesex, and indeed the kingdom in general, is much indebted for the assistance it affords, not only as an easy and cheap conveyance of the products of our island, but also as being the means of bringing to our

very doors the various productions of the whole habitable globe; serving at the reflux of the tide as a useful drain to carry off the filth and superfluous water of the capital and surrounding country: then, by the wonderful chemical operations of nature, returning to us with its excellent purified stream,

Though deep, yet clear; though gentle, yet not dull;
Strong without rage; without o'erflowing, full!

The river Lea forms the eastern border of the county. The Brent, the Coln, and the small river Carn, are also rivers of this county; and the Regent's Canal and Park are now amongst its beautiful geographical features.

From the Brent is derived the name of the county town, Brentford. This is indeed called the county town, and here the elections for the county take place; but it is a low, miserable place, with scarcely a good house in it. The Serpentine River in Hyde Park is artificial, made about the year 1730. Spring water is to be obtained in many parts of the county at a small expense of sinking, and there are several mineral springs. But little can be said of the natural produce of this county. It owes almost every thing valuable of this nature to cultivation. There are no mines in the county; nor have any metallic strata been discovered here.

Middlesex returns fourteen members to parliament: viz. two for the county, four for the city of London, two for the city of Westminster, two for the borough of Finsbury, two for Mary-le-bone, and two for the Tower Hamlets. See LONDON 510

The eminent persons that have been born in this county are almost too numerous even for a bare list of names. For the sake of uniformity, however, such a list shall be here attempted:—Michael Alford. Jacob Allestrey. Edward Alleyn. Launcelot Andrews. Francis Anthony. John Anthony. John Argall. John Arnold. William Arnell. Dr. T. Arne. George Ashton. Albricius, a physician and philosopher of the eleventh century. George Ashwell. Francis Bacon. John Bacon. Henry Baker. Joshua Barnes. Dr. Isaac Barrow. Thomas Birch. William Bowyer. Thomas Broughton. Sir Thomas Browne. James Butler. Richard Owen Cambridge. William Camden. Sir Thomas Chaloner. Geoffry Chaucer. Charles Churchill. Colley Cibber. Susanna Maria Cibber. Dr. John Colet. Anthony Ashley Cooper, earl of Shaftesbury. Samuel Cooper. Abraham Cowley. William Cowper, dean of Durham. John Davenport. Thomas Day. Dr. John Dee. John Dennis. Dr. Philip Doddridge. John Donne. John Ellis. Thomas Farnaby. Thomas Flaxman. Dr. W. Fleetwood. Dr. T. Franklin. John Gale. Richard Gough. John Gaunt. Thomas Gray. Dr. Maurice Green. Sir Thomas Gresham. Dr. Edmund Halley. Robert Harley, earl of Oxford. John Hampden. Dr. William Hawes. James Heath. John Henderson. John Heywood. Eliza Heywood. Joseph Highmore. Aaron Hill. Bishop Hoadly. Dr. J. Hoadly. William Hogarth. Thomas Holcroft. Thomas Hollis. John Hoole. John Hoppner. Bishop Horsley. Dr. John Jebb. Soame Jenyns. Ingulphus. Inigo Jones. Sir W. Jones. Dr. J. Jortin. J. Keeple. Anne Killigrew. Dr. William King. Thomas King. Dr. S. Knight. J. Leland. Wm. Lowth. Isaac Madox. Michael Maittaire. Henry Mill. John Milton. Sir Thomas More. George Morland. Thomas Mortimer. John Motley. Robert Nelson. George North, M. A. Anne Oldfield. John Palmer, the comedian. Samuel Paterson, the bibliographer. William Penn, the Quaker, of immortal memory. Catherine Phillips. Alexander Pope. Percival Pott, F. R. S. James Quin, the comedian. Isaac Reed. Dr. William Rowley. William Seward. James Shirley. Stephen Skinner. Rev. Dr. Thomas Smith. Edmund Smith. Dr. Daniel Charles Solander. Edmund Spenser. P. D. Stanhope, earl of Chesterfield. George Stepney. John Stowe. John Strype. James Stuart, called Athenian Stuart. Sir William Temple. Bonnel Thornton. Andrew Tooke. Thomas Twining. Richard Verstegan, antiquary, &c. George Vertue. Dr. John Ward. Thomas Wentworth. Bulstrode Whitelock. John Wilkes. Henry Woodward, comedian. Daniel Wray. All the above, and doubtless many more, many of them equally deserving of notice, were natives of London. The following were born, most probably, in some other part of the county:—Henry Aldrich. Eustace Andrews. Sir Arthur Aston. Allen Bathurst. Thomas à Becket. Henry Bennet. T. Betterton. Sir Thomas Pope Blount. Anthony Collins. Martin Folkes. Dr. John Hough, bishop of Worcester. John Howard, of immortal memory. Sir William Killegrew. Thomas Killegrew Dr. H. Killegrew. Dr. William King. Dr. R. Mead. James Nares. Lacy Ryan. Dr. Robert South. Dr. Brook Taylor. Dr. Joseph Toms. Edward Vernon. Paul Whitehead.

The manufactures, trade, and commerce of Middlesex embrace every species of traffic, art, and occupation, that the whole kingdom itself can boast. See, however, the description of LONDON.

MIDDLESEX, a county of Massachusetts, North America, is bounded north by New Hampshire, east by Essex county, south-east by Norfolk county, and west by Worcester county. Population 52,789. Chief towns Charlestown, Cambridge, and Concord.

MIDDLESEX, county of Connecticut, is bounded north by Hartford county, east by New London county, south by Long Island Sound, and west by New Haven county. Population 20,723. Chief town, Middletown.

MIDDLESEX, county of New Jersey, is bounded north by Essex county, east by Staten Island and Raritan Bay, south-east by Monmouth county, south-west by Burlington county, and north-west by Somerset county. Population 20,381. Chief towns New Brunswick, and Amboy.

MIDDLESEX, county of the east part of Virginia; bounded N. N. E. by the Rappahannock, east by Chesapeake Bay, south and south-west by Mathews, Gloucester, and King and Queen counties, and north-west by Caroline county. Population 4414. Slaves 2476. Chief town Urbanna.

MIDDLETON (Dr. Conyers), a celebrated English divine, the son of a clergyman in Yorkshire, was born at Richmond in 1683. He distinguished himself, while fellow of Trinity College, Cambridge, by his controversy with Dr. Bentley his master, relating to some mercenary conduct of the latter in that station. He afterwards had a controversy with the whole body of physicians, on the dignity of the medical profession; concerning which he published De Medicorum apud veteres Romanos De gentium Conditione Dissertatio; qua, contra viros Celeberrimos Jacobum Sponium et Richardum Meadium, servilem atque ignobilem eam fuisse, ostenditur. Hitherto he had stood well with his clerical brethren; but he drew their resentment on him in 1729, by writing A Letter from Rome, showing an exact conformity between popery and paganism, &c.; which appeared dangerous to the cause of miracles in general. In 1741 came out his great work, The History of the Life of M. Tullius Cicero, 2 vols. 4to.; which is indeed a fine performance. In 1748 he published A Free Enquiry into the Miraculous Powers which are supposed to have subsisted in the Christian Church from the earliest ages, through several successive centuries. He was now attacked from all quarters; but, before he took any notice of his antagonists, he supplied them with another subject in An Examination of the Lord Bishop of London's Discourses concerning the use and extent of Prophecy, &c. He was in 1723 chosen principal librarian of the public library at Cambridge; and, if he rose not to dignities in the church, he was in easy circumstances, which enabled him to assert a dignity of mind often forgotten in the career of preferment. He died in 1750, at Hildersham in Cambridgeshire, an estate of his own purchasing; and in 1752 all his works, except the life of Cicero, were collected in 4 vols. 4to.

MIDDLETON (Sir Hugh), a public-spirited goldsmith and citizen of London, born at Denbigh; to whom the inhabitants of that great city are indebted for the benefit of the New River, which he began February 20th, 1608, after the scheme had been given up as impracticable, by uniting two streams in Middlesex and Hertfordshire; and at last happily accomplished in 1613, but at the expense of his whole fortune. King James I., who greatly approved and patronised the plan, and agreed to pay half the expense, rewarded his public spirit by creating him a knight, and afterwards a baronet. Sir Hugh died in the reign of Charles I. and left a share in the New River to the poor of the Goldsmith's Company.

MIDDLETON (Thomas Fanshaw), D.D. F.R.S., the first bishop of Calcutta, was the son of the rector of Kedleston, Derbyshire, and born in 1769. He was educated at Christ's Hospital, and proceeded upon a school exhibition to Pembroke Hall, Cambridge, where he took his first degree in 1792. He took orders this year as curate of Gainsborough in Lincolnshire, where he wrote a periodical paper called The Country Spectator. Attracting, in 1794, the attention of Dr. Pretyman, archdeacon of Lincoln, he employed him as a tutor to his sons, and obtained for him the rectory of Tansore, to which, in 1802, was added in commendam that of Little and Castle Bytham. The late Rev. R. G. Robinson LL.B., vicar of Harborne, &c., was the friend to whom the bishop's father was indebted for the opportunity of placing his son at Christ's Hospital. This circumstance the bishop never forgot; for Mr. R. was among the first to hear of any success of the bishop's, and Mr. R.'s son was pressed very much by him to accompany him to India as his chaplain. The following is an extract of a letter to Mr. R. from the bishop:—

Peterboro', May 29, 1795.

'Mr. Pretyman has presented me to the rectory of Tansore, in Northamptonshire, and I am now at Petersborough for institution. I give you almost the earliest intelligence of this affair, because I am aware that this, and every other success which may attend me, must ultimately be ascribed to you.'

He took his doctor's degree in 1808; and the same year appeared his work on the Greek Article, the doctrine of which he has most ably illustrated. In 1809 he was promoted to a stall in the diocese of Lincoln, the vicarage of St. Pancras, Middlesex, and the rectory of Puttenham, Herts: in 1812 he was made archdeacon of Huntingdon. When government resolved to establish a bishop in India, Dr. Middleton was selected for that station, and, being consecrated at Lambeth in May, arrived at Calcutta in November, 1814. In 1820 he laid the foundation stone of Calcutta church, and a school for the education of the Christian poor: a missionary college was soon after established. Dr. Middleton died in the midst of these labors of a fever, July 8th, 1822. His sermons and charges have been collected by Dr. Bonney into 1 vol. 8vo., with a biographical memoir.

MIDDLETOWN, a town of the United States, the capital of Middlesex county, Connecticut, is situated on the west bank of Connecticut River, thirty-four miles above its mouth. It is a pleasant and flourishing town, and has considerable trade and manufactures. It contains a court-house, a jail, four churches for Congregationalists, Episcopalians, Independents, and Baptists. It has, besides, a large woollen manufactory. The river is navigable to this place for all vessels drawing ten feet of water; and in 1816 the quantity of shipping that belonged to the port amounted to 19,499 tons. Two miles from the city is a lead mine. Population 2014; and, including the township, 5382. Twenty-five miles N. N. E. of New Haven. 2. A township of the United States, in Monmouth county. New Jersey, south of Raritan Bay. Population 3849. 3. A flourishing town of the United States, in Dauphin county, Pennsylvania, situated on the north-west side of Swatara Creek, a little above its junction with the Susquehannah. It carries on a considerable trade in wheat and flour. Ninety-two miles west by north of Philadelphia. 4. A township of the United States, in Delaware county, New York. Population 2318. 5. A township of Bucks county, Pennsylvania. Population 1663. 6. A township of Delaware county, Pennsylvania. Population 948.—It is also

the name of various inconsiderable townships in the United States.

MIDDLEWICH, or MIDDLEWICK, a town of Cheshire, 166 miles north-west of London. It stands near the conflux of the Croke and Dan, below the junction of the Wheelock and Dan, where are two salt-water springs, from which are made great quantities of salt, the brine being said to be so strong as to produce a full fourth part salt. It is an ancient borough, governed by burgesses, and its parish extends into many adjacent townships. It has a spacious church, and a market on Tuesday; and fairs on St. James's day, July 25th, and Holy Thursday. It has an inland navigation of above 500 miles, by the Mersey. See MERSEY. It lies twenty-four miles east of Chester.

MIDHURST, a town of Sussex, which has been represented in parliament ever since the 4th of Edward II. It is a neat small town, on a hill surrounded with others, having the river Arun at the bottom; and is a borough by prescription, governed by a bailiff, chosen annually by a jury at a court-leet of the lord of the manor. It has a market on Thursday; fairs on March 21st, and the Thursday after. It is 11 miles north by east of Chester, and 50 west by south of London. It sends one member to parliament.

MIDIAN, or MADIAN, in ancient geography, a town on the south side of Arabia Petræa; so called from a son of Abraham by Keturah.

MIDIAN, a town near the Arnon and Æoplis, in ruins in Jerome's time.

MIDIANITES, the people of Midian. With their daughters the Israelites committed fornication and idolatry. A branch of the Midianites dwelt on the Arabian Gulf, and were called Kenites; some of whom turned proselytes, and dwelt with the Israelites in the land of Canaan.

MIDNAPORE, a district of Bengal, once a portion of Jellasore, and of the province of Orissa, but transferred to Bengal about the year 1706. It contains 6000 square miles and 1,500,000 inhabitants. For a long period in the hands of the Afghauns it has a greater number of Mahometans than most other districts. It was ceded to the East India Company by the nabob Cossim Aly Khan. It contains a great number of small forts, one of which was some time since discovered in the middle of a forest, containing twenty pieces of cannon, in an unserviceable state. These old forts and the forests still serve as a refuge for robbers. Midnapore, though not so fertile as Burdwan, produces abundance of sugar, grain, tobacco, cotton and indigo. Its chief manufacture is sannas, a fine calico. Its chief towns are Midnapore, Jellasore, Piply, and Narraingur; its rivers the Cassia and Subunreeka.

MIDNAPORE, the capital of the above mentioned district, formerly possessed a brick fort, surrounded by a ditch. This is now converted into a jail. It is the station of a judge, collector, &c., and has a cantonment for two battalions of infantry. Long. 87° 25′ E., lat. 22° 25′ N.

MID'RIFF, *n. s.* Sax. mıðhpıꝼe; Goth. *midrif*, *mid* and *hrife*, the belly. The diaphragm. See the extract from Quincy.

Whereat he inly raged, and, as they talked,
Smote him into the *midriff* with a stone
That beat out life. *Milton's Paradise Lost.*

In the gullet, where it perforateth the *midriff*, the carneous fibres of that muscular part are inflected. *Ray.*

The *midriff* divides the trunk of the body into two cavities; the thorax and abdomen: it is composed of two muscles; the first and superior of these arises from the sternum, and the ends of the last ribs on each side. The second, and inferior muscle, comes from the vertebræ of the loins by two productions, of which that on the right side comes from the first, second, and third vertebræ of the loins: that on the left side is somewhat shorter; and both these productions join and make the lower part of the *midriff*. *Quincy.*

MIDWIFERY.

MID'WIFE, *n. s.* } MID'WIFERY. } From the Goth. *mit*, *met*, wise, cunning, and rif (*huif*, a woman's hood) wife: Scot. *cannie wife*. Skinner and Junius confound the first syllable with the Sax. mıð, meed, a reward. But the French retain the old northern idea of the word in their *sage femme*, and the Dutch in their *vroed-moeder*, wise mother or woman. Strictly, a woman who assists the human female in child-birth: in the modern acceptation midwifery includes the medical treatment, by either sex, of all the symptoms and consequences of pregnancy, and of the child or children produced, while suckling. See below.

And it came to pass, when she was in hard labour, that the *midwife* said unto her, Fear not; thou shalt have this son also. *Gen.* xxxv. 17.

Without a *midwife* these their throes sustain,
And, bowing, bring their issue forth with pain.
Sandys.

When man doth die, our body, as the womb,
And as a *midwife*, death directs it home. *Donne.*

There was never any thing propounded for publick good that did not meet with opposition; arising from the humour of such as would have nothing brought into the world but by their own *midwifery*.
Child's Discourse on Trade.

There saw I how the secret felon wrought,
And treason labouring in the traitor's thought,
And *midwife* time the ripened plot to murder brought.
Dryden.

I had as clear a notion of the relation of brothers between them, as if I had all the skill of a *midwife*.
Locke.

So hasty fruits, and too ambitious flowers,
Scorning the *midwifery* of ripening showers,
In spight of frosts, spring forth the' unwilling earth.
Stepney.

But no man, sure! e'er left his house
And saddled Ball with thoughts so wild,
To bring a *midwife* to his spouse,
Before he knew she was with child. *Prior.*

History of Midwifery.

Midwifery, in the present and extended import of the term, includes not only the assistance directly afforded to women in the act of child-birth, but the relief of the diseases connected with their sexual system, as well as those of their infants during the period of lactation.

We shall endeavour to present to our readers a brief, yet a connected sketch, of this branch of medical science; dwelling very slightly on the early periods of its history, when the notions of the ancients were so erroneous, and their practices so absurd, as scarcely to reward the trouble of investigation.

The practice of midwifery, or rather the bestowment of help on parturient women, was almost co-existent with the human species. 'There must have been a time,' says Dr. Denman, 'when the rude but well-meant endeavours of one friend to relieve another in distress ceased, and application was made to those who were supposed to have more information or greater skill. This would properly be the origin of the art.'

From all the passages of Scripture where midwives are mentioned, it is plain that women were the only practitioners of this art among the Hebrews and Egyptians. It is equally certain that the Greeks and the Romans confided this most important branch of medicine to women. Rachel, the wife of Jacob, and Thamar, who was delivered of twins, were assisted by midwives. Pharaoh, king of Egypt, commanded the midwives to destroy all the male children of the Hebrew women; but they nobly disobeyed. Phanarete, the mother of Socrates, was a midwife; and Plato explains the functions, and regulates the duties undertaken by these females. He remarks that at Athens they had the right of proposing and making marriages. Hippocrates, Aristotle, Galen, and Ætius, allude to midwives in their works; and Aspasia, who was probably celebrated amongst the women of this order, is not unfrequently cited by Ætius.

These instances are interesting, inasmuch as they prove that a distinct class of females was employed to render assistance in labor. In these early ages every circumstance would favor the health and energy of the species; and where the difficulties of parturition were trivial, not arising from malconformation or a debilitated system, a little longer time, and the encouragement of the midwife, associated perhaps with manual help, more apparent than real, would be amply sufficient to overcome every obstacle. In other instances, as we cannot suppose they enjoyed an entire exemption from pelvic deformity and extensive hæmorrhage, more especially at Athens and Rome, where luxury and voluptuous dissipation were widely prevalent, such assistance as the imperfect state of their knowledge on this subject enabled them to bestow could not have prevented a most painful mortality amongst parturient women. It ought, however, to be remembered, that the warmth of the climate would exert a genial influence, and very much facilitate the progress of labor. To this circumstance we may perhaps fairly attribute a great portion of that success, which to us, at this period, appears to have exceeded any reasonable expectation.

Hippocrates, who practised medicine in Greece 460 years before the Christian era, is styled by some authors the father of midwifery as well as of physic. It is needless to dwell on the unbounded veneration with which his name has been regarded by succeeding ages. His works will ever excite the highest admiration, as carrying with them indubitable proofs of profound and laborious research. His sagacity and experience fully entitle him to our praise; and yet, by only glancing at his obstetric views, we shall afford our readers ample means to estimate the very little progress which the science had then made. To female diseases, not immediately associated with parturition, he evidently paid much attention; there was little or no difficulty in the way of personal observation, and his opinions and method of treatment are to this day, in some measure, the objects of enquiry.

In midwifery, on the contrary, he had no such opportunities; his information was not gained at the bedside of the patient. The precise character of the circumstances to be remedied, and the 'ratio medendi' of the means proposed, came to him through the medium of persons incapable of forming a correct opinion, and of making a just report. It is not wonderful, therefore, that we now smile at his notions, and hold in little estimation his uncouth and curious remedies. He is, notwithstanding, a splendid example of ancient medical knowledge and practice.

Hippocrates was acquainted with no other kind of natural labor than that in which the head presents. Here, if the progress was slow and difficult, he recommended sternutatories; and, if these failed, the patient was to be held by the shoulders, and gently shaken at intervals till her pains expelled the child. He represents presentations of the feet as generally fatal; and in these, as well as where the arm, leg, or side presents, he recommends returning them as soon as possible into the uterus, and to bring down the head. If from any untoward circumstance, as the death of the child, or the swelling of its body, its delivery could not be effected, he directs that it shall be brought away piece-meal. His injunctions relative to the management of the placenta are replete with danger. Its immediate extraction is recommended; and pulling at the funis, in various ways, is the principal method of procedure. From this period till after the commencement of the Christian era midwifery made no progress. Celsus, who flourished in the reign of the emperor Tiberius, A. D. 37, although an ardent admirer and a close copyist of Hippocrates, threw some new light on parturition. He recommended, in the case of a dead child, the introduction of the hand; and the delivery by the feet in cases where the arm presented; and was of course aware of the error of Hippocrates in attaching such fatal consequences to footling cases. He also recommends the dilatation of the os uteri, from which, however, little benefit and much injury may often arise. This improved method of delivery did not meet with all the credit and support which it deserved; for Galen, who lived A. D. 131, about 600 years after Hippocrates, condemned it as decidedly as his great predecessor had done.

Pliny too, who lived under Vespasian and Titus, accords with Galen; and, although not a physician himself, attests the opinions of the physicians of his time. He asserts the difficulty attendant on labor where the feet present, denominates it preternatural, and adds, that children coming into the world in this manner were called agrippa, that is to say, born with much difficulty.

This opposition to delivery by the feet was not easily overcome; for, although men of reputation approved and recommended it, we find that, as late as the middle of the seventeenth century, Riverius publicly condemned footling labor; and Mauriceau remarks, in the first edition of his book printed in 1664, that many authors were still of opinion that, in such cases, it would be better to turn, and bring down the head of the child. After having, however, observed that it is difficult, if not impossible, to execute this, he concludes, 'it is much better to extract the child by its feet, when they present, than to run the hazard of doing worse by turning it.'

The advantages of this first great improvement in obstetric science are so apparent, and the principle on which it proceeds is so simple,—so superior to the laborious, and in many cases insuperably difficult and dangerous practice of bringing down the head, that we are filled with surprise at the hostility opposed to its adoption. It is impossible to place in a clearer light, the ignorance and irresponsibility of the writers and practitioners of midwifery at this period; they propose almost as a universal remedy a procedure which can rarely be adopted with safety, and the employment of which must have been attended, in the majority of instances, with the most calamitous results. Turning a child, by the most skilful practitioner, and in the most favorable circumstances, is a truly undesirable occurrence; we can, therefore, easily conceive its consequences in such a rude and undigested condition of the principles and practice of the art.

It would seem no useful purpose to dwell on the series of writers who succeeded Celsus; they were, for the most part, devoted followers of Hippocrates; and, where this was not the case, they were little more than transcribers of each other. Amongst the number may be mentioned Moschion, in the reign of Nero; Rufus, Ephesius, Galen, in the reign of the emperor Adrian; Oribasius, and Paulus Ægineta, who closes the list of ancient Greek writers on medicine.

Le Clerc, in whose History of Physic much curious and very interesting matter will be found, places Paulus at the end of the fourth or the beginning of the fifth century; at or before which period the western Roman empire had been overturned by the Goths and Vandals. Le Clerc supposes that the celebrity of Alexandria, for centuries the chief seat of philosophy and science, though now past the meridian of its splendor, had induced him to prosecute his studies in that city; to have done which, according to Ammianus Marcellinus, in the time of the emperor Valens, was a sufficient pretence for any one to commence the practice of physic.

Soon afterwards the library of Alexandria was burned, its scientific treasures were dispersed, and its learned men driven into exile by the ruthless hand of Mahometan intolerance. Thus terminated the splendor of the last of the ancient schools. But the Saracens were happily destined in their turn to carry forward philosophical and intellectual enquiries; and in Arabia astronomy, geometry, and medicine, were cultivated with great zeal and no small success. Nor can we forget that to them we are indebted for the use of numerical characters, and that their physicians first presented to the world an account of the small-pox. Yet our notices of the medical writers of this school must necessarily be brief; although, as they devoted themselves in some degree to midwifery, our history would be imperfect were we not to present to our readers some short abstract of their labors.

Serapion treats, at some length, of the diseases of pregnant women, with the method of cure.

Rhazes follows in the same course, and advises the membranes to be ruptured by the nail, or by a small knife, when, by their roughness, they impede the labor.

Avicenna, who lived at Ispahan about the year 1000, possessed amazing celebrity, and his writings maintained their fame till the restoration of learning. It was he who gave the first description of the forceps, or an instrument to be employed in difficult parturition, with the double purpose of saving the life both of the mother and the child. In all preternatural cases Avicenna adheres to the erroneous practice of reducing the head into the natural position; but where this is impossible he enjoins delivery by the feet, and pronounces it the safest of the preternatural presentations.

Albucasis, the last Arabian writer to be mentioned here, lived in the eleventh century at Cynopolis, on the Caspian Sea; and according to Dr. Smellie, to whom we are indebted for some valuable facts introduced in this sketch, 'is the same person who was also known by the name of Alsaharavius, at least so it appears from an Arabian manuscript now in the Bodleian library.' Albucasis has merely followed his predecessors, annexing a more particular description of the instruments then used in midwifery.

Having thus briefly traced the progress of medical science, so far as midwifery is concerned, from the earliest ages, we must remark that about this period (the twelfth century) the study of physic began to decline in the east. We have already seen that at the destruction of the Alexandrian library the dispersion of the learned in different countries was productive of good. By these events, in themselves so disastrous, science was diffused over many parts of the world, which might otherwise have remained in darkness and error.

After the conquest of Rome by Odoacer, the eastern part of this vast empire survived for many centuries. Constantinople, its capital, was distinguished not only by its splendor and magnificence, but by its cultivation of the arts. Men, devoted to science, here found an asylum, till its final subjugation by the Turkish arms,

under Mahomet the Second. But the religion and manners of the Turks were most unfavorable to literature; they were led to circumscribe all philosophy and knowledge within the narrow limits of their own intolerant and fanatical faith. It is therefore naturally to be supposed that individuals devoted to literary pursuits would seek elsewhere the tranquillity which the barbarity of their conquerors would necessarily deny. So that the wisdom of Providence in this, as in other instances, educed extensive good for mankind from devastation and war.

Many of these individuals would doubtless repair to the schools which had been established in Italy since the eighth century, from which western Europe first derived their knowledge; and amongst these Padua was especially famous for the cultivation of medicine. It must also be remembered that the darkness of the middle ages was now passing away; that the dawn of that day had appeared, which, in its full splendor, was to enlighten the whole of Europe, and to create a period distinguished by historians as the 'revival of letters.' The minds of men, too, were arising, perhaps for ever, from the ignorance and degradation in which they had been so long lost; and the art of printing, now fully established, had removed every serious impediment to the attainment and distribution of human learning. The accumulated stores of the ancients were exposed to observation and enquiry throughout Europe; and the Greek MSS. preserved after the destruction of Alexandria, and which had been already translated into the Syriac, Persian, and Indian languages, were brought from Constantinople by the learned Greeks, after the taking of that city in the year 1453. The universities of Paris and Montpelier succeeded those of Italy, and continued, till the eighteenth century, to attract not only the students of medicine, but those also who were desirous of improvement in general literature and science.

But it is now time to direct the attention of our readers nearer home, and to trace before them the progress which medicine, and more especially midwifery, were destined to make in England. It would be very easy to show that our own country has afforded no pleasing exception to that slow and very gradual attainment of knowledge which has marked the early history of all nations. The wars in which the Britons were so frequently engaged were little conducive to scientific attainments; and perhaps no individual before Roger Bacon, who flourished in the thirteenth century, ought to be considered as at all learned. This enquiry is however foreign from our purpose. We shall, therefore, at once remark that the establishment of the College of Physicians in London, by the charter of king Henry VIII. in 1518, may be considered almost the first event directly favorable to the improvement of medicine. Linacre, a man, according to Dr. Freind, of a bright genius and clear understanding, as well as unusual knowledge in different parts of learning, was its first president, and remained so till his death. He published a translation in Latin of different parts of Galen, of which it has been remarked that, from the exactness and propriety of the style, any one might have supposed it was written in a classical age. Dr. Freind in eulogising Linacre, more especially for the foundation of the college, observes, 'The wisdom of such an institution speaks for itself. His scheme without doubt was not only to create a good understanding and unanimity among his own profession (which of itself was an excellent thought), but to make them more useful to the public; and he imagined that by separating them from the vulgar empirics, and setting them upon such a reputable foot of distinction, there would always arise a spirit of emulation among men liberally educated, which would animate them in pursuing their enquiries into the nature of diseases, and the methods of cure for the benefit of mankind. And perhaps no founder ever had the good fortune to have his designs succeed more to his wish; this society having constantly produced one set of men after another, who have done both credit and service to their country by their practice and by their writings.' In proof of this statement we may refer to the discovery of the circulation of the blood by Harvey, to the labors of Glisson on irritability, to those of Willis on the brain and the nervous system, and to the great improvement of our knowledge of the glandular and lymphatic systems by Joliffe, Wharton, and Needham, and more especially in later times by Dr. W. Hunter.

Dr. Denman laments that Linacre did not print his works in English, in which language they would have been generally read, have afforded immediate instruction, stood as good examples, and taught a proper method of writing. He attributes to this defect of Linacre the continuance of English medical writers in their former style; and for many years little real progress in knowledge was made, or any titles heard of but those of Urinals, Judgment of Urynes, Anatomy of Urynes, Treasures of Health, Mirroures of Health, &c. In 1540 was published the first book on the subject of midwifery in England, entitled The Byrth of Mankynde, otherwise named The Woman's Book, by Thomas Raynold, physician; it underwent a second edition by Thomas Ray a printer, whose name is not much known. It was illustrated with prints, and was held in high estimation. Dr. Raynold informs his readers that this book had been translated from the original Latin some years before by a studious and learned clerk; who having performed the task incorrectly, he, Dr. Raynold, had been at great pains to revise and enlarge it in another translation. Its original author, according to Dr. Smellie, was Eucharius Rhodion, whose book was in great esteem all over Germany; and in the year 1532, being translated into Latin and other languages, from the original high Dutch, became universally the Woman's Book over all Europe, and was introduced into England, when it was translated by this Dr. Raynold.

In the year 1578 the celebrated Harvey was born at Folkstone in Kent, and, having completed his studies at Cambridge, he went to Padua, where he graduated in 1602. In 1603 he published his treatise on generation; and afterwards,

engaging in the practice of midwifery, he published his Exercitatio de partu. Sydenham also soon afterwards noticed the diseases incident to childbed women, and those of young children.

It is now proper to remark that more general attention began to be bestowed on midwifery; its great importance, as a part of the healing art, was fully appreciated; and the example of Harvey, who had personally engaged in its practice, was followed by the calling in of men practitioners in all difficult cases. Astruc assures us that the epoch of the employment of men midwives goes no farther back than the first lying in of madame De la Valière, mistress of Louis XIV., in 1663. She sent for Julian Clement, a surgeon of high reputation. He was conducted with great secresy to the house, the lady's face was covered with a hood, and the king is supposed to have been concealed in the curtains. The same surgeon was employed in the subsequent labors of this lady, and, as he was very successful, men midwives afterwards came into repute; the name of accoucheur being given to them.

It is then the fact that obstetric science made but little progress in Europe till the seventeenth century. The very reverse of this appears to be the case in China. In that empire, according to the latest accounts, both physic and surgery are still in a state of the utmost degradation; but, for some hundred years, the art of midwifery has been practised by a set of men destined to the purpose by order of government. These men, who hold in society the same rank which lithotomists formerly did in this country, are called in whenever a woman has been a certain number of hours in labor, and employ a mechanical contrivance for completing the delivery, without injury to the infant. A certain number of these individuals is allotted to each district of a certain population. It is said that the Chinese government was led to make this provision in consequence of many women dying undelivered, and that, in the majority of cases, the obstacles might have been removed by very simple mechanical expedients. These facts were communicated by a gentleman who resided upwards of twenty years as surgeon to the British factory at Canton.

About 1634 the works of Ambrose Paré, the first modern who had made any considerable improvement in midwifery, were given to the world. The reputation of Raynold's book, which had maintained its standing for nearly a century, was now destroyed. Paré expressly orders, in all preternatural cases, that the child shall be turned, and brought away by the feet, thus at once deviating from the erroneous practice of the ancients, which had in a greater or less degree prevailed until his day. At this time surgery was more cultivated in Paris than in any part of the world; and the obstetric department of the Hotel Dieu was erected, into which poor women with child, destitute of the necessaries of life, were admitted. In the year 1668 Mauriceau published a Treatise on Midwifery, which exceeded every thing before made public on that subject. He gives a very full account of all the different kinds of labor; and the book having been translated into English, by one of the sons of the celebrated Dr. Chamberlen, it continued in great estimation for many years. Dr. Chamberlen and his three sons were contemporary with Mauriceau, and for some time they preserved to themselves the exclusive advantage arising from the knowledge of the forceps and lever. Chapman, however, made public a description of this instrument in 1773; although, previously to this period, instruments, differing from those described by the Arabian writers, had been used in Germany, France, and other places. The success attendant on the practice of the Chamberlens induced a too frequent use of the forceps; which gave rise to publications, impugning the propriety of interfering with the efforts of nature, and of any endeavours to hasten the birth of the child.

Dr. Maubray, the first public teacher of midwifery in this country, coincided in these views and in a book entitled The Female Physician, or the whole Art of new improved Midwifery, he violently declaims against the use of instruments. The names of Dionis and Deventer may be next mentioned, both of whom concurred in deprecating the use of instruments in midwifery. Deventer was originally a watchmaker. He entertained the opinion that the wrong positions of the os internum and fundus uteri are the principal causes of lingering, difficult, and dangerous labors.

In 1727 appeared Dr. Simson's work, entitled The System of the Womb, a production of considerable ingenuity, but not of much use in practice. Chapman, who was the second public teacher of midwifery in London, published a Treatise on its Improvement in 1773. His description of the forceps appeared in the third volume of the Edinburgh Medical Essays. In the year 1734 Dr. Hody published A Collection of Cases in Midwifery, written by Mr. William Giffard. He gave a plate representing the forceps; and was, it is generally believed, the first who asserted that the placenta might be attached over the os uteri.

About this time lived Sir Richard Manningham, who devoted himself to the practice of midwifery, and established a small hospital for the reception of parturient women only, which was the first thing of the kind in the British dominions.

It is, perhaps, scarcely necessary to pursue this narrative any farther. The names of Smellie, Dr. William Hunter, Denman, and of Levnet, in France, are familiar to all professional readers, and a perusal of their works cannot fail to excite a high admiration of their talents and industry. To use the words of Dr. Denman, 'The English might be said from this time (1740) to have been in full possession of the subject; all the books written in the neighbouring countries being translated, public lectures given, and hospitals established, for the further improvement of the art · and, as all the books printed since that time may readily be procured, every one has an opportunity of forming his own opinion of their respective merits.'

A variety of circumstances thus concurred to forward the progress of the obstetric art; and it may with truth be affirmed that, although its cultivation was so long deferred, it has attained a degree of certainty and perfection which places it at least in an equal, if not a superior rank, with any other department of medicine. We are well aware that many other distinguished individuals might be mentioned, who have contributed very largely to the general store of obstetric knowledge; but some of them are still living; and we much prefer an allusion to their individual contributions in the subsequent part of this treatise, bringing forward their opinions on those subjects which they have either discovered, illustrated, or confirmed.

We shall comprise the whole of our remarks on midwifery in four divisions:—

I. We shall first explain the obstetric properties of the pelvis, carefully noticing those deviations which may obstruct parturition. Under this head we shall treat on the healthy and morbid circumstances of menstruation.

II. The second division will include the description of the gravid uterus, with the doctrines of conception, sterility, and the signs and diseases of pregnancy.

III. In the third part of the treatise we shall dwell very fully on labor, in all its varieties, and on the various kinds of flooding.

IV. And, to conclude, we shall treat as briefly as possible, consistently with practical purposes, on the diseases which occur soon after delivery.

PART I.

EXPLANATION OF THE PELVIS.

1. It is not our intention to enter at large into the anatomical description of the bones, joints, and ligaments of the pelvis: we shall consider them only so far as they are essentially connected with parturition and its consequences; the minuter details having been already dwelt upon in an earlier part of this work.

2. We find in the fœtus and young subject, that the pelvis is composed of eight bones, viz. two ossa ilia, two ossa pubis, two ossa ischia. the sacrum, and the coccyx. Till the age of puberty these bones remain distinct, and this arrangement obviously affords mobility, and allows the bones to adapt themselves to pressure. In difficult parturition therefore, and especially in breech presentations, labor may be thus somewhat facilitated. In the adult, on the contrary, from the consolidation of the bony structure, we can enumerate only four bones: the ossa innominata, or side bones of the pelvis; the sacrum fitted in behind, and serving as a basis for the support of the spine; and the os coccygis subjoined to the end of the sacrum.

3. *Ossa innominata.*—These bones form the principal part of the bulk of the pelvis, yet they are not very essentially connected with parturition. Bearing in mind that each os innominatum is made up of three distinct bones, the ilium, the os pubis, and the ischium, it is easy to understand the construction of the anterior curve of the outlet denominated the arch of the pubes. The anterior part of the ossa pubis forms its top, the processes of the ischia and pubes its sides, and the tuberosity of each ischium its base. Each os innominatum may also be divided into the body and wing, and it is by their junction with each other that an angle or edge is formed, which is known by the appellation of the brim of the pelvis.

4. *Sacrum* is a bone of considerable size, triangular in its shape, and curved, its convexity being posterior, its concavity in front, this latter part being denominated by accoucheurs the hollow of the sacrum. At the basis of this triangular bone there is a middle projection, which, in connexion with the body of the last lumbar vertebra, forms what is so frequently mentioned in midwifery, the promontory of the sacrum.

5. *Os coccygis.*—This bone possesses a considerable degree of interest to the accoucheur. It is usually described as consisting of one piece only. This, however, is not correct, it being in reality made up of several, not unfrequently connected together by cartilage, hence acquiring a certain degree of flexibility, and in consequence a slight power of adaptation during the passage of the head of the child. In a few instances this bone is anchylosed with the sacrum, and in consequence is shortened and turned inwards, so as to diminish the advantages which are obtained by its receding when the child comes into the world. Denman says, that the impediment occasioned thereby at the time of labor may be, and usually is, overcome by the force with which the head of the child is propelled, and the os coccygis is again separated from the sacrum, with a noise loud enough to be distinctly heard. He had known more than one circumstance of this kind. Burns observes that by falls or blows it may be luxated; and if this be not discovered, and the bone replaced, suppuration occurs about the rectum, and the bone is discharged. The insertion of the coccygei muscles of a portion of the levatores ani, and of slips of the sacro-sciatic ligaments into the sides of the coccyx, keep it steady and prevent any lateral motion.

6. *Ligaments.*—The obturatores, and the external and internal sacro-ischiatic ligaments, alone possess obstetric importance, and they have been fully described in another place.

7. *Joints.*—The hip, the lumbar, the sacro-iliac joints, the sacro-coccygeal joints, and the symphyses pubis, may all be enumerated as belonging to the pelvis; but the last three claim from us peculiar attention.

8. *Sacro-coccygeal joint.*—This joint, as we have already observed, is moveable, enlarging, perhaps posteriorly, the outlet of the pelvis, to the extent of an inch. Its construction is similar to the other joints of the body. It has articulating surfaces invested with cartilage and covered with synovial membrane. A capsular ligament connects the two bones arising all round from the extremity of the sacrum, and inserted all round into the base of the coccyx; this completing the articulation. This joint is occasionally the subject of disease.

9. Its *anchylosis* we have already mentioned, which Dr. Blundell (see his Lectures, reported in the Lancet) thinks of very rare occurrence; and he believes it still more rarely produces any serious obstruction to parturition. We have, however, seen one case in which the birth of the child was very much retarded by the encroachment of this bone on the capacity of the inferior outlet of the pelvis. It much more frequently happens, says Dr. Blundell, that instead of anchylosis there is a rigidity of the parts. A woman may be forty years of age before she is married, and perhaps has a child at forty-one; her health being vigorous, her flesh firm, her fibre rigid and unyielding. Now here a rigidity of the sacro-coccygeal joint, with a rigidity of all the adjacent parts, may prove a very formidable obstacle to labor, requiring the most able and judicious management. There can be no doubt, and the occurrence is admitted and provided for by Dr. Blundell, that in a case of this kind the perforation may be required. It more frequently happens, however, that the obstruction yields to powerful uterine efforts, and that no further injury ensues than a painful degree of tenderness, produced by inflammation about the joint. Such was the result, in the instance we have mentioned, where the lady for some months was compelled to resort to a contrivance when sitting, by which she avoided the possibility of pressure on the part.

10. In Dr. Denman's admirable work on Midwifery cases of the disruption of the sacro-coccygeal joint are mentioned. It is evident their treatment must be conducted on the general principles of surgery; and care must be taken that in their re-union the coccyx does not encroach on the capacity of the pelvis.

11. It is scarcely necessary to state that inflammation of these joints will require the employment of the same means which are resorted to in inflammation of other parts of the body; such as leeches, cupping, fomentation, and a regimen of the antiphlogistic kind, suited to the strength of the patient.

12. In scrofulous individuals the treatment must be modified. Sea air, sea bathing, and generous diet, being invariably productive of the most benefit.

13. *Symphysis pubis.*—This joint has engrossed a large share of obstetric attention, and has ever been thought of great importance. It does not vary in its structure from other joints; it unites the ossa innominata in front, the ends of which are invested with cartilage, connected together by an interarticular portion of fibrous substance. The principal strength of this joint depends on its capsular ligament, the fibres of which are far more numerous on the outer than on the inner part, an arrangement wisely intended to prevent any narrowing of the antro-posterior diameter of the pelvis, in which direction contraction or deformity is most frequently found.

14. The symphysis pubis is occasionally the subject of acute inflammation, which goes on to the suppurative stage: this may arise spontaneously or from injury done to the joint; but it is more frequently associated with gestation. The pain and heat about the part, its tenderness when pressed, and above all the exacerbation of suffering on the slightest motion of the joint, cannot fail to lead us to the seat of disease. It is here manifestly desirable to put a period to the malady in its earliest stage, and to prevent the formation of matter.

15. General and local blood-letting, purgatives, diaphoretics, and above all rest, cannot be too strictly enjoined. If, notwithstanding the adoption of these measures, suppuration should ensue, it will be easily ascertained. In some cases the general disturbance of system may be so great, that the patient may sink before the evacuation of matter: in others, who are more robust, the ligament may yield to absorption, and the pus may thus make its escape; it will however be the duty of the practitioner, if the irritation be alarming, to anticipate this giving way of the ligament, and, by opening the joint, to procure for its contents an early vent.

16. *Sacro-iliac joints.*—These are susceptible of inflammatory action, and sometimes, though very rarely, of suppuration. Mr. Mansfield Clarke, in his very able work on the diseases of women accompanied with discharge, mentions relaxation of these joints as not of infrequent occurrence. Pain in the back, and an incapability of standing for half a minute unless supported on each side, are the diagnostic symptoms. Time is here the principal remedy, although considerable relief may be obtained from the application of a well-adjusted bandage. It is worthy of remark that the same arrangement of ligamentous fibres occurs here as in the symphysis pubis, the greater portion being found on the outer side of the joint: a provision intended no doubt to prevent any impediment to the passage of the child.

Of the Separation of the Bones of the Pelvis.

17. Great difference of opinion has existed on this point. It is a fact that, in many mammiferous animals, immediately previous to labor, a relaxation of ligaments, producing a separation of the joints, does occur. Ruysch and Harvey, judging from their own observations, were convinced that a similar separation almost invariably takes place in the human female. Dr. Denman was inclined to believe that the degrees of separation of the junctions of the bones of the pelvis may be very different, and that when it proceeds beyond a certain degree it is to be considered as morbid. Smellie ventures to assert, from experience and observation, that this separation is by no means a usual symptom, though sometimes it may happen, in which case the patient suffers great pain, and continues lame in those parts for a considerable time after delivery. Burns considers the separation as no advantage, but a serious evil; and in cases of deformed pelvis, when we should naturally look for its operation, did it really exist, we do not observe it taking place.

18. It is well known, he says, to every practitioner, that owing to the distension of the muscles during pregnancy, very considerable pain is sometimes felt at the insertion of the rectus muscle into the pubes, and it is also known, that sometimes, in consequence of pregnancy,

the parts about the pelvis, and especially the bladder and the urethra, and even the whole vulva, may become very irritable. This tender state may be communicated to the symphysis, or some irritation less in degree than that already mentioned may exist, which, in particular cases, seems to extend to the articulation, producing either an increased effusion of interstitial fluid in the intermediate cartilage, and thus loosening the firm adhesion of the bones; or a tenderness and sensibility of the part, rendering motion painful. In either case exertion may produce a separation, and certainly in some cases has done so. The separation is always attended with inconvenience, and often with danger, especially when it occurs during parturition; for abscess may take place, and the patient sink under hectic fever; or inflammation may be communicated to the peritonæum, and the patient die in great pain.

19. For ourselves we are not inclined to believe that any such invariable relaxation of the joints of the pelvis, as would materially facilitate the progress of difficult labor, forms any part of the parturient process; and we are the more inclined to this opinion from the fact that, when any separation has occurred sufficient to produce this result, it has been much more than compensated by increased suffering at the time, and by a painfully prolonged inability to walk afterwards.

Of the Pelvis, considered in relation to the practice of Midwifery.

20. Having thus described the various bones, ligaments, and joints, of which the bony case of the pelvis is made up, we shall now point out the obstetric properties which attach to the pelvis as to a whole; and, in doing so, our remarks will refer to what may be denominated a standard pelvis, or that which is most frequently found, when the skeleton is well formed.

21. The pelvis of the human species, which is stronger in proportion to its size than in any quadruped, may be considered as an arch, supporting the weight of the superincumbent body. Its position is such that a line passing from the third lumbar vertebra will fall upon the superior edge of the symphysis pubis: the cavity of the pelvis being projected so far backwards that the ossa pubis principally sustains the enlarged uterus in advanced pregnancy. Hence we see the reason of that weakness and pain which during this state is so frequently referred to the junction of these bones.

22. It is perhaps worthy of remark, even in so condensed a treatise as the present, that the powers and properties of the pelvis depend much on its position. Dr. Denman observes that, in those animals which possess the greatest share of strength, the position of the pelvis is nearly perpendicular, and the two apertures of the cavity nearly horizontal, as may be seen in the elephant. In those which are distinguished by their speed or agility the position of the pelvis is nearly horizontal, and the two apertures nearly perpendicular, as may be seen in the stag. In mixed animals, or those in which strength and speed are united, the position of the pelvis is neither horizontal nor perpendicular, but inclined, so as to partake, by different degrees of inclination, of the advantages of either position, as may be seen in the horse and ass.

23. Accoucheurs usually divide the pelvis into two regions, the one lying above, the other below the brim, the former being the false, the latter the true pelvis. Of that region which is lying above the brim it will be sufficient to observe, that anteriorly it is wide open, being bounded posteriorly by the lumbar vertebræ, and laterally by the iliac fossæ. Its breadth, from the anterior superior spine of one ilium to another, is usually eight or nine inches, and its depth from three to four. It is evident that if the abdominal parietes are relaxed by the recumbent position, and the elevation of the knees and shoulders, we shall be able to examine the contents of this region satisfactorily, and ascertain pretty correctly any morbid circumstances connected with the pelvic viscera. The true pelvis, which as will readily be conceived is of great importance in the practice of midwifery, has been divided into three parts, the brim, the outlet, and the intermediate cavity; or supposing the whole of the true pelvis to form a kind of canal, whose entrance and outlet are somewhat narrower than the middle, it has been distinguished into the superior strait, the inferior strait, and an excavation.

24. The brim is generally of an oval figure, the long measure being from side to side, and the short diameter from before backward. The average measurement of the short diameter is four inches, five inches from side to side, and five and one-eighth, or five and one-fourth, for the oblique diameter, which is described by a line stretching from the back of the acetabula to the sacro-iliac synchondroses.

25. The brim varies in its make, being in some circular, in others more oval, in some small, in others large, but in general it is of an elliptical form, the regularity of the oval being broken by the promontory of the sacrum. The thorough comprehension of these simple facts will exert a very powerful influence on the management of cases where there is any deviation from the natural progress of parturition. In an ordinary labor, when the vertex of the child presents, we find, in the commencement of the process, that the face is lying towards one side of the pelvis, and the occiput towards the other; and thus, as the long axis of the head of the child corresponds with the long diameter of the brim of the pelvis, we find that it rapidly descends.

26. If, however, this state of things be reversed, and the head of the child be so placed that its face, instead of lying laterally, is situated in front, it is very evident that difficulty must arise, as the long axis of the head is directly opposed to the long axis of the brim; and if the head be large and the pelvis small, or if labor has proceeded so far that the head is wedged in its situation, we may be compelled to use the perforator.

27. In presentations of the feet, if the pelvis should be small and the head large, the child may be lost, and the soft parts of the mother materially injured, by want of attention to these

facts. Now, in these cases, if, instead of any violent efforts at extraction, the practitioner were adroitly to introduce his hand, and turn the face of the child to the one side of the pelvis, so as to make the long measure of the head correspond with the long measure of the brim, the progress of the labor would be facilitated, and the difficulty overcome.

28. It is also worthy of remark that, when we introduce the hand into the uterus, a proceeding never to be adopted without absolute necessity, we should carry it forward, when near the brim, by the side of the aperture, because there we find most room.

29. In the dimensions of the inferior aperture, or outlet, the proportions are reversed; the narrowest part being from side to side. This however, it must be recollected, is entirely owing to the retreat of the coccyx, in consequence of the pressure it sustains from the child's head. From side to side the diameter is four, and, from before backwards, five inches. The form of the inferior aperture is very irregular, consisting, according to Dr. Blundell, to whose very valuable and comprehensive lectures, published in the Lancet, we are much indebted, of three large scallops, one upon either side, and one in front, of vast obstetric interest, known under the name of the arch of the pubes. If, however, we examine a pelvis, with the ligaments still in connexion, the shape of the outlet is quadrangular. It is here necessary to dwell for a moment, as it is important in practice, on the difference between the long axis of the brim, which is from side to side, and that of the outlet, which is from before backward.

30. The head of a child enters the pelvis with the face to one side , and the occiput to the other; before it emerges a change in its situation occurs, and the face is thrown into the hollow of the sacrum, while the occiput is found under the arch of the pubes. The reason of this procedure is plain : the long axis of the head is thereby made to correspond with the long axis of the outlet, and in crural presentations it is very necessary to attend to this point of anatomy; for if at the brim there be great difficulty, when the axes are in opposition at the outlet, we shall find an equal obstacle if the face be situated towards the pubes instead of in the hollow of the sacrum.

31. We cannot better impress this fact on the minds of our readers than by the statement that the cavity of the pelvis is incurvated, and that, in consequence of this incurvation, a straight line will not pass through its centre. The axis of the brim is downward and backward; that of the outlet is downward and forward; and the line of motion of the child's head must of course correspond to the axis of that part of the pelvis in which it is situated.

32. In the cavity of the pelvis we must especially notice the hollow of the sacrum, as the facility or difficulty of parturition very much depends upon it. It serves as a receptacle, making room for whatever part of the child may be descending, in presentations of the vertex, of the face, and of the breech.

33. The depth of the pelvis is a point of consequence, more especially in estimating the progress of labor. We find at the symphysis pubis it does not exceed an inch and a half, or at most two inches, posteriorly from the base of the sacrum to the point of the os coccygis; when under pressure it is about four times as deep as in front; and laterally the depth of the inferior extremities of the ischia is about four inches. Bearing these facts in mind we shall not always allow ourselves to imagine, because we can readily feel the child's head in the front of the pelvis, that its birth is instantly to take place; but, remembering the intermediate depth of the pelvis laterally, and its very much greater depth posteriorly, we shall be fully aware that difficulty may be experienced from incarceration.

34. In making examinations it is well to avail ourselves of the shallowness of the pelvis in front, which affords the utmost facility for carrying the fingers considerably beyond the brim. We may remark here that the arch of the pubes in ordinary labor, when the head is at the outlet, serves the very important purpose of allowing the occiput sufficient space to lie forth in front, by which it relieves the pressure, and facilitates the passage of the face through the hollow of the sacrum.

35. The upper edge of the ossa pubis is slightly everted, thus preventing any impediment to the entrance of the head of the child into the cavity of the pelvis; and, at its lower edge, there is some degree of divergence; an arrangement by which the advancing motion of the head is very much facilitated.

36. We cannot better conclude our observations on the general properties of the female pelvis than by pointing out its bearing on the spine, and by a description of those marks which distinguish it from the pelvis of the male.

37. By the plane of the brim, says Dr. Blundell, is meant an imaginary surface, closing in the superior aperture of the pelvis, and forming a sort of flooring there. The pelvis unites with the spine in such a bearing that the plane and the spine form an obtuse angle with each other; the sacrum lying above and posteriorly; the symphysis anteriorly, and below. In the living female, when the womb, enlarged by gestation, is resting on the brim, the mouth or neck lie inferiorly and backward, while the fundus or upper parts are placed anteriorly so as to lie out beyond the ensiform cartilage. By a knowledge of these facts we are enabled to place our patients in positions which will materially facilitate obstetric operations.

38. In placing the brim vertically the body should be inclined forwards in its horizontal position; the patient should be placed in the semi-recumbent posture, or half sitting, half lying; if, for the reduction of a retroverted uterus, it is desirable to invert the plane of the brim, this may be effected by placing the patient on her knees and elbows.

39. The observation that the whole of the female skeleton is in general smaller, lighter, and smoother than that of the male, is particularly applicable to the female pelvis; in addition to which we cannot fail to notice that the spines and processes of the ossa innominata are farther distant from each other.

40. The os sacrum is broader and incurvated to enlarge the cavity of the pelvis. The wings of the ossa ilia are flatter and more expanded: in the male the brim of the pelvis is circular, and has its greatest extent between the ossa pubis and os sacrum; in the female the brim is oval, and the largest diameter is from side to side.

41. In the male the pelvis is of considerable depth; in the female it is shallow. The arch of the pelvis in the male is contracted; in the female it is capacious to make room for the head of the child. In the male the outlet is small; in the female of considerable capacity.

42. *Of the head of the child, and its passage through the pelvis.*—Having now completed our observations on the pelvis generally, and having noticed its particular properties, and the various purposes they are intended to promote, we shall proceed to examine the structure and dimensions of the child's head; as, on the proportion which these measurements bear to the bony canal through which it is destined to pass, the facility or difficulty of delivery will much depend. The head, which is oviform in its shape, has its greatest length from the chin to the vertex, which, on the average, is about five inches and a quarter; from side to side, between the tuberosities of the parietal bones, the measure is three inches and a half; from the lower part of the occiput to the upper part of the forehead it is about four inches; and, from the lower part of the forehead to the upper part of the occiput, about four inches and a half. These are the average or standard dimensions of the head; yet it is clear, owing to the nature of the sutures, and the conformability of the bones, the shape of the head may be altered, and its length be increased, while its breadth is diminished. Dr. Joseph Clarke (Philosophical Transactions, vol. lxxvi.) says that the size of the male head is generally a twenty-eighth or thirtieth part larger than that of the female; and he farther supposes that one-half more of our males than females are born dead, owing to tedious labor, or increased pressure on the brain; and to the same causes he ascribes the greater number of deaths of males soon after birth. In twin cases again, as the children are smaller, he calculates that only one-fifth more of males than females are still born.

43. The head of the child differs from the head of the adult; the cranium of the latter is completely ossified, and consequently firm, compact, and unyielding. The fœtal cranium, on the contrary, is made up of various bones, loosely connected by membranes, and possessing a degree of flexibility, which admirably adapts it to the pressure it may have to sustain in its transmission through the pelvis. Its sutures are not riveted together, the bony edge of one bone being directly united with the bony edge of the adjoining, as in the adult: they are maintained in connexion by the interposition of cartilage; and hence arises the great conformability of the fœtal skull, the advantage of which cannot fail to be perceived when its bulk is greater than natural, or when there is any diminution of the capacity with any deformity in the shape of the pelvis.

44. The frontal, the parietal, the occipital, and the temporal bones, compose the projecting part of the cranium, and it is in the connexion of these bones by suture that certain indications arise which it is of great importance to the accoucheur fully to understand.

45. The frontal suture unites the two pieces of the os frontis together, and is stretching from the sagittal suture to the root of the nose. The coronal suture extends across the head from ear to ear, crossing the sagittal and frontal at right angles, and joining the os frontis to the ossa parietalia. The lambdoidal suture is situated posteriorly, and unites the occipital bone with the ossa parietalia. The sagittal, the most important suture of all in practice, passes from the front of the head to the back, uniting the ossa parietalia to each other. If we examine the fœtal head still further we shall perceive two openings, formed by a deficiency of bony matter, which slightly pulsate, and which are denominated the fontanels. The large fontanel is situated anteriorly, at the junction of the sagittal and frontal with the two limbs of the coronal suture; it may be distinguished by its quadrangular shape, by its extent, and by the meeting of four sutures for its formation. The lesser fontanel is situated posteriorly at the point of union between the sagittal and lambdoidal sutures, and is distinguished by its triangular shape, and by the meeting of only three sutures for its formation. These remarks comprise the whole of what is important to be known, in relation to the standard head of the fœtus; and we shall now pass on to explain the mode by which the child passes into the world, previously premising that by the term presentation we mean that part of the child which lies over the centre of the pelvis, and by the term situation, when speaking of the passage of the child through the pelvis, we mean its place in relation to the surrounding bones. Thus, when the vertex presents, one ear is situated in the symphysis pubis, and the other to the sacrum, the face is towards one side of the pelvis, and the occiput to the other.

46. Burns, in the third section of his fifth chapter, has given a very simple description of the progress of the head through the pelvis, which we shall present to our readers. He says, by comparing the size of the head with the capacity of the pelvis, it is evident that the one can readily pass through the other. But he apprehends that the comparison is not always correctly made; for the child does not pass with the long diameter of its cranium parallel to a line drawn in the direction of the long diameter of the brim of the pelvis, but it descends obliquely, so that less room is required. The central portion of the sagittal suture passes first, the chin being placed on the breast of the child. Now, the length of a line, drawn from the nape of the neck to the crown of the head, is three inches and a half; a line intersecting this, drawn from the one parietal protuberance to the other, measures no more. We have, therefore, when the head passes in natural labor, a circular body going through the brim whose diameter is not above three inches and a half, and thus no obstacle or difficulty can arise from the size of the

pelvis. There is so much space super-abounding, betwixt the pubes and the sacrum, as to prevent all risk of injury from pressure on the bladder, urethra, or rectum; and, as the long diameter of the head is descending obliquely, the sides of the brim of the pelvis are not pressed on. This is so certainly the case that the head may, and actually often does, pass without any great additional pain or difficulty, although the capacity of the pelvis be a little contracted. But when the shoulders, which measure five inches across, come to pass, then the brim is completely occupied. If, however, any contraction should take place in the lateral diameter, the child would still pass one shoulder, descending obliquely before the other.

47. It is of great consequence to understand the passage of the child's head in natural labor, for upon this depends our knowledge of the treatment of difficult labor. The head naturally is placed with the vertex directed to one side, or a little towards the acetabulum; and the forehead, owing chiefly to the action of the promontory of the sacrum, is turned in the same degree towards the opposite sacro-iliac junction. When labor begins and the head comes to descend, the chin is laid on the sternum, and the central portion of the sagittal suture is directed downwards, nearly in the axis of the brim of the pelvis, when, by the contraction of the uterus, the head is forced a little lower, its apex comes to touch the plane of the ischium. Upon this the posterior sloping part of the parietal bone slides downwards and forwards, as on an inclined plane, the head being turned gradually, so that in a little time the face is thrown into the hollow of the sacrum, and the vertex presents at the orifice of the vagina. This is not fully accomplished till the cranium has got entirely into the cavity of the pelvis. As the basin is shallow at the pubes, the head is felt near the orifice of the vagina, and even touching the labia and perinæum, before the turn is completed, and when the ear is still at the pubes. The head, while its long diameter lies transversely, continues to descend in the axis of the brim of the pelvis, but when it is turned it passes in the axis of the outlet. When the turn is being made the direction of the motion is in some intermediate point; and this fact should, in operating with instruments, be studied and remembered.

48. When the pelvis is narrow above, and the sacrum projects, the hemispherical part of the head is long before it reaches the inclined plane of the ischium; and, when the head is lengthened out so as to come into contact with it, we find that, although the projection of the sacrum directs the vertex sometimes prematurely a little forward, yet the tendency to turn fully is resisted by the situation of the bones above, a great part of the cranium and all the face being above the brim, and perhaps in part locked in the pelvis. By a continuation of the force, the shape of the head may be altered; even the vertex may be turned a little to one side, its apex not corresponding exactly to the extremity of the long diameter of the head; the integuments may be tumefied, and a bloody serum be effused between them, so as greatly to disfigure the presentation. As therefore in tedious labor, occasioned by a deformed pelvis, the skull may be much lengthened and misshapen, we are not to judge of the situation of the head by the position of the apex of the tumor which it forms; but we must feel for the ear, which bears a steady relation to that part of the head which presents the obstacle. The back and upper part of the head are compressible, but the base of the skull and face are firm. A line drawn from the neck to the forehead, passing over the ear, is to be considered as the boundary betwixt these parts of opposite character; and therefore we attend to the relative situation of the ear, as it ascertains both the position of the head and its advancement through the brim.

49. *Of deformity of the pelvis.*—Under this appellation we intend to class all those deviations from the standard pelvis which at all interfere with the natural progress and completion of labor. It will be manifest, from a slight examination of the deformed pelves which are to be found in our museums, that distortion may arise from various causes, and that no part of this bony structure is exempted from its prejudicial influence. It is, however, a pleasing circumstance, that we do not frequently meet with those higher degrees of contraction which require us to sacrifice the life of the child to the safety of the mother.

50. Fracture and rickets are not infrequent causes of a distorted pelvis; but to mollities ossium, or a softness of the bones, we may attribute the majority of cases; and here the false as well as the true pelvis partakes of the deformity, and, of this latter region, both the brim and the outlet may exhibit incurvation. Frequently, where there is a good deal of distortion about the pelvis generally, certain parts may suffer much less than others; thus while the brim is greatly distorted the outlet may deviate but slightly from the standard dimensions. Specimens are in existence which, while they show great contraction or distortion on one side, make a near approximation to the natural dimensions on the other.

51. Dr. Blundell observes that, these distortions of the pelvis occurring, there is no end to the variety of forms the bones may assume; nevertheless he has observed, on making an examination of his specimens, that there are two leading shapes or forms to which these varieties may be reduced, and which may not be inaptly denominated the angular and the ellipsoidal.

52. At the brim we sometimes meet with elliptical distortions produced by the approximation of the promontory of the sacrum towards the symphysis pubis, the length of the brim being increased between the sides, and abbreviated between the front and back. At the outlet, also, the ellipsoid contraction may occur, the symphysis pubis being approximated to the lower extremity of the sacrum and the coccyx, so as to obstruct or render impracticable the passage of the fœtus, even after its bulk has been reduced by the perforation.

53. The second variety, or the angular form of distortion, is produced at the brim in consequence of the acetabula and the promontory of the sacrum being all of them pushed inward upon the

axis of the pelvis; of this kind of distortion Dr. Blundell once possessed an example in which the acetabula and promontory were so nearly approximated that the brim was, as it were, divided into three fissures, two laterally and one in front. At the outlet, also, the angular distortion occurs; and here it is occasioned by the approach of the tuberosities of the ischia, and the incurvation and advance of the sacrum and coccyx.

54. We believe that, in the greater number of instances of deformity, the brim of the pelvis is principally in fault; and that, when the contraction of this part is so considerable as to require the employment of instruments, it will most frequently be found narrowed from before backwards and not from side to side: the contraction here may arise from an approximation of the ossa pubis to the sacrum, or from the acetabula encroaching upon the diameter of the brim in the same direction.

55. In addition to these obstacles to parturition, there may be impediments arising from other causes. Exostosis from the pelvis bones may materially diminish the capacity of the brim, the intermediate cavity, or the outlet. Steatomatous and scirrhous tumors, incapable perhaps from their size or hardness of being pushed out of the way of the child's head may as seriously obstruct the progress of labor, as though they were producing absolute distortion. An enlarged ovarium or vaginal hernia may oppose delivery, and instances are on record where such obstacles have been attended with fatal results.

56. Mr. Burns once met with a dreadful case of tumor obstructing delivery, which we shall relate in his own words, as it is highly creditable to his skill and courage. The attachments of this tumor were so extensive, and it was of so great size as to fill the pelvis, permitting only one finger to be passed between it and the right side of the basin. It adhered from the symphysis pubis round to the sacrum, being attached to the urethra obturator muscle and rectum intimately adhering to the brim of the pelvis, and even overlapping it a little towards the left acetabulum. It was hard, somewhat irregular, and scarcely moveable. The patient was in the ninth month of pregnancy; there was no choice, except between the Cæsarian operation and the extirpation of the tumor. The latter was agreed on, and with the assistance of Messrs. Cowper, Russell, and Pattison, Mr. Burns performed it on the 16th of March, a few hours after slight labor pains had come on. 'An incision was made on the left side of the orifice of the vagina, perinæum and anus through the skin, cellular substance, and transversalis perinei muscles. The levator ani being freely divided, the tumor was then easily touched with the finger. A catheter was introduced into the urethra, and the tumor separated from its attachments to that quarter. It was next separated from the uterus, vagina, and rectum, partly by the scalpel, partly by the finger. I could then grasp it as a child's head, but it was quite fixed to the pelvis. An incision was made into it with the knife, as near the pelvis as possible; but, from the difficulty of acting safely with that instrument, the scissors, guided by the finger, were employed when I came near the back part; and, instead of going quite through, I stopped when near the posterior surface, lest I should wound the rectum or a large vessel, and completed the operation with a spatula. The tumor was then removed, and its base or attachment to the bones dissected off as closely as possible. Little blood was lost, the pains immediately became strong, and before she was laid down in a bed they were very pressing. In four hours she was delivered of a still-born child above the average size; peritoneal inflammation, with considerable constitutional irritation, came on; but, by the prompt and active use of the lancet and purgatives, the danger was soon over, and the recovery went on well. In the month of May the wound was healed. On examining her vagina, the vagina is felt adhering as it ought to do to the pelvis, rectum, &c. The side of the pelvis is smooth, and a person ignorant of the previous history of the case, or who did not see the external cicatrix, would not be able to discover that any operation had been performed. After a lapse of more than two years she still continues well.'

57. A small pelvis will occasionally give rise to difficulty in parturition; for although it generally happens, if the woman be small, that her child will be small also, and as this kind of pelvis exists apart from contraction, maintaining indeed its shape and symmetry, labor will very frequently proceed with facility. Yet it may so happen that a small woman shall produce large fœtuses. An instance of this lately occurred to us, where, in consequence of the disproportion existing between the child and the pelvis, we were compelled to use the perforator, after having in vain employed the forceps.

58. The treatment of these cases is by no means easy; we are only aware, indeed, of two methods, by which, if the deformity extreme, and the full term of pregnancy be completed, women can be relieved from this most calamitous situation. We may perform embryotomy or the Cæsarian operation. And, in relation to the first of these proposals, Burns has ascertained that when the standard head is reduced in the best possible way, by the removal of the frontal, parietal, and squamous bones, it will require for its passage an aperture of three inches in length, and of one inch and three quarters in breadth. If this space does not exist, the Cæsarian operation, of the success of which we do not in this country entertain any very favorable anticipations, must be resorted to.

59. Mr. Barlow, of Blackburn, used to relate the following case:—A robust countrywoman in vigorous health, the mother of several children, was thrown out of a cart, which went over her and broke her pelvis to pieces. She was carried home, and lay a long time; but at last recovered. She again became pregnant, and was attended by a woman; but the pelvis was so contracted by the displacement of the fractured bones, and the mass of osseous matter by which they were consolidated, that the midwife was unable to deliver her. Mr. Barlow was now called in, and was persuaded she could not be delivered without the Cæsarian operation. As

soon as she was willing to submit to it, feeling there was no hope in any other way, he performed it, and a dead child was extracted. The mother herself did very well; in a fortnight after the incisions were made she got up, and in three weeks she was attending to her usual concerns.

60. In cases where the deformity does not so materially diminish the capacity of the pelvis as in the instances we have described, we shall be justified in waiting for the full exertion of the natural powers. The obstacle may exist in one particular point of the brim, and, this being surmounted, the future progress of the labor may be uninterrupted. We have ourselves been surprised, after waiting twenty-eight hours without any advance of the head, and having determined to perforate, suddenly to discover that the difficulty was overcome, and the labor was completed with unusual celerity. It may appear singular, but it is nevertheless true, that such changes do arise as sometimes to render the use of instruments unnecessary in a labor occurring in immediate succession to one where their employment had been absolutely required. We were once called to a case of presentation of the breech, where, owing to contraction of the brim, from before backwards, we were compelled to diminish the capacity of the head before we could extract the child. This lady again became pregnant, and at the commencement of labor it was ascertained that the vertex presented, the waters passed off, and the pains continued remarkably powerful and forcing for eighteen hours. At the expiration of this time she was much exhausted, but the head remained immoveably jammed at the brim. The long forceps was applied, but no justifiable force which could be exerted with it enabled us to surmount the obstacle, and we were at length driven to the use of the perforation. In a third labor of this lady, occurring at the full time, although summoned very early we could not reach her before the birth of an average-sized child. A fourth labor, in which we have only a few weeks since attended her, has proved equally fortunate, and the child is by no means small.

61. Dr. Blundell's rule in cases of this kind, and indeed whenever instruments are thought to be required, is remarkably simple and very applicable. If, says he, no dangerous symptoms appear, we ought to give a fair trial to the full efforts of the uterus for twenty-four hours, after the discharge of the liquor amnii, abstaining as long as may be from the use of instruments, for they are great evils, and a meddlesome midwifery is bad. But should dangers arise referrible to the prolongation of the labor, or should the woman be in labor for twenty-four hours after the discharge of the waters, the head not advancing, a trial of the lever or forceps becomes necessary. Further, should the dangerous symptoms become pressing, or should the womb have been in action for eight-and-twenty hours, the head still not advancing, the perforator must be employed. Again, a woman may have had several children destroyed in succession, and, pregnancy still occurring, she is very anxious to become the mother of a living child. Here we may propose to induce labor at seven months, or seven months and a fortnight; thus preventing that complete growth of the fœtus which in all probability renders its destruction unavoidable; and, as children do live when born at this period, we give our patient a chance of bringing into the world a living child.

62. It is possible that women who are known to have very considerable deformity of the pelvis may become pregnant; and perhaps this may occur after their lives have been put in the utmost jeopardy by a previous case of embryotomy. Dr. Blundell has made a proposition for the management of these cases, which deserves to be mentioned. Let us suppose that a woman is not advanced above two or three months, and that an attempt to discharge the liquor amnii has failed. Under these circumstances he strongly recommends an opening to be made a little above the symphysis pubis, in or near the linea alba, carefully avoiding the bladder; at this opening introduce the fore finger of the left hand, so as to get a bearing on the uterus; this accomplished, take some slender-pointed instrument, and pretty stiff, and, by a sort of acupuncture, carry this instrument through the body of the uterus into its cavity, and on entering the uterine cavity move the wire cautiously, yet effectually, in different directions, so as to break the ovum all to pieces, and put an enectual stop to the generative process. The ovum destroyed, draw up the fallopian tube, which is easily done; first on the one side, then on the other, cutting out a portion of it, so as to render it impervious, by which you secure future sterility. In performing the operation great care is to be taken that the ovum is thoroughly broken up, even if it occupy fifteen or twenty minutes.

63. *Large pelvis.*—Having described the difficulties incident to those deviations from the standard pelvis which are produced by contraction and distortion, as well as those which arise from a pelvis naturally small, yet retaining its symmetry and shape; we shall now detail the inconveniences produced by a pelvis exceeding in its dimensions that which we denominate standard.

It is very evident that difficulty in the passage of the child cannot originate from a pelvis of this kind. The uterus may, however, in consequence of augmented pelvic capacity, remain long below the brim, and thus increase the probability of its prolapse; and, if the bladder be distended, of its retroversion.

64. These are circumstances which will readily suggest themselves on the slightest reflection, and we need not dwell on the treatment by which they must be remedied. Another, and perhaps the most serious evil arising in cases of this kind, is the suddenness with which labor may come on, the uterus descending to the orifice of the vagina before the os tincæ is fully dilated. We were in attendance not long since on a patient who had borne many children, where the pelvis was capacious, and the softer parts relaxed. A few monitory and slight pains had been experienced, but as there was scarcely any progress made, we were preparing to leave the house; before we reached the door one single

pain expelled the child. Occurrences of this nature should induce great caution whenever we are called upon for a legal opinion. A woman, pregnant perhaps for the first time, and of an illegitimate child, is naturally ignorant of the changes which precede labor; her pelvis is unusually large, and in an attempt to relieve the bowels the child is suddenly precipitated into a situation where its destruction is inevitable. All this may occur without any guilty intention on her part to sacrifice the infant; and in a court of law she ought to have the full benefit of these palliative circumstances.

65. *Deviations from the standard head.*—A head unusually small, as we have just now observed of a pelvis unusually large, can originate no difficulties in parturition. The converse of this proposition is true of a head which exceeds in its dimensions that with which we generally meet; more especially if the pelvis be small, and the bones of the head more than commonly ossified.

66. When the vertex or face has been long incarcerated at the brim, or in the cavity of the pelvis, it is very possible to be deceived as to the part which really presents. If the face be over the centre of the pelvis it may suffer compression, the blood accumulating, and the soft parts becoming swelled and tense. Here we do not find the inequalities which generally characterise this presentation; the same remarks may be reiterated of the vertex, where it has been long detained in its passage through the pelvis. We have seen many cases where the scalp has been so exceedingly tumefied as to resemble the breech more than the head. The hydrocephalic cranium may generally be detected by the distension and stiffness of the vertex, by the breadth of the sagittal suture, and perhaps by an obscure fluctuation in this part, and towards the fontanel. We are not always to suppose that a watery head presents insuperable obstacles to the completion of the birth by the natural efforts; give to these efforts a fair trial, and the result will frequently exceed the most sanguine expectations; for, although there are many in which instrumental aid will be required, yet if we act in accordance with the rule already laid down, of not interfering till after a certain period, and not even then unless symptoms arise plainly indicative of constitutional and local excitement, we shall frequently be gratified by the emergence of the head, without the assistance of either the forceps or the perforator. These remarks are equally applicable when there is disproportion between the size of the head and the capacity of the pelvis; ever remembering that the bones of the fœtal cranium may by compression very much overlap each other, and thus its bulk may be so far diminished as to bring it within the successful influence of the uterine powers.

67. We cannot better conclude this section of our subject than by quoting the words of Bandelocque, a name of high repute in obstetric science. 'The accoucheur,' says this author, 'who has not yet by long practice enabled himself to form a just estimate of the process of nature, may easily deceive himself in these cases, and in the first judge a delivery to be impossible which is ready to terminate, and in the second declare that to be easy which is about to be opposed by difficulties, that art can alone surmount; or which at the least, render it extremely tedious and painful. More than forty persons were witnesses to the disagreeable consequences of a mistake of this kind, in a woman whose pelvis he possessed. The operator having pronounced that the woman would be speedily delivered, on account of the facility with which the child's head had engaged with the first pains, and attributing the obstacles which soon after obstructed its passage to another cause, and not to the narrowness of the inferior strait, which had remained unnoticed, he waited two days in perfect security; and then, by a more blind temerity than the former, used the crotchet on a child whose life might have been by other means preserved.

68. *Of pelvimeters, or the examination necessary to ascertain whether the pelvis be well or ill formed.*—A variety of instruments have been devised for obtaining an accurate knowledge of the different measurements of the pelvis; some being constructed for the attainment of this information from within the pelvis, while others, with the same design, have only been intended for external application. It is evident that much difficulty must be experienced in the use of mechanical means for this purpose; and, even when employed successfully, we doubt whether their indications be superior to those which may be procured by the skilful and experienced enquiry of the fingers. We believe, if the fore finger be passed to the brim of the pelvis, a sufficiently correct notion of its capacity for obstetric purposes may be secured, by carefully noting the length of space it requires to pass from the symphysis pubis to the promontory of the sacrum, and the extent it must traverse before it can stretch from one side to the other. By moving about the fingers in the cavity and the outlet, similar information may be acquired; and if in addition to all this we ascertain whether the head has entered the brim to any extent, and the time which has been required for the progress thus far, we shall not be very ignorant of the dimensions of this most important part. The only pelvimeter we have seen, of easy application, is one designed to measure the pelvis externally. It may be denominated a pair of callipers, one leg of which is fixed on the symphysis pubis, and the other a little below the spine of the last lumbar vertebra, three inches being allowed for the thickness of the sacrum and the symphysis: thus, if the thickness of the whole be seven inches, we deduct three, leaving four inches as the measurement of the brim, in its antro-posterior diameter. Bandelocque expresses himself well pleased with this kind of measurement, and says that he has not found a difference of a line in the examination of five-and-thirty pelves, distorted and contracted in all ways and in all possible degrees. The roundness of the hips, and their equality, the prominence of the mons veneris, the space of eight or nine inches between the anterior superior spines of the ossa ilia, and the moderate depression of the superior and posterior parts of the sacrum, are evidences of a

favorable conformation. The converse of these circumstances, more especially if there be any curvature of the lumbar spine, denotes a faulty construction of the pelvis.

69. *Of the soft parts contained within the pelvis.*—The observations hitherto made on the pelvis have referred to that condition where it is divested of the lining it receives in the recent state, from muscles as well as from ligamentous and membraneous expansions. There can be no doubt, that the structure of parts is much better understood in this way; for, by regarding them at first as they really are in the skeleton, we acquire much clearer notions of the purposes they serve, of the manner in which other parts exert their influence upon them, and of the combined and finished operations of the whole. The necessity of some lining of this kind is sufficiently manifest when we consider the importance and delicacy of the organs situated in the pelvis; among which may be enumerated the uterus, urethra, bladder, and ovaries, fallopian tubes, rectum, &c.

70. The pelvis has been frequently described as connected with the cavity of the abdomen; but, as we shall not meddle either with the structure or diseases of the abdominal organs, it appears desirable to look upon the pelvic cavity as distinct from that of the abdomen. We find two muscles at each side of the pelvis internally, the iliacus and the psoas. The former by its radiated fibres fills up the iliac fossæ; and the psoas, originating from the lateral parts of the lumbar spine, descends to the inner edge of the brim to be inserted with the psoas, into the trochanter minor of the femoral bone. The levator ani is arising from the whole circumference of the brim of the pelvis, and descending, may be traced all the way round to the extremity of the rectum. Under the symphysis it is pierced by the urethra and vagina, and, during the passage of the child's head, it is easy to suppose that these fibres must be considerably stretched and distended.

71. From the membrane that fills up the thyroid hole, and from the inner surface of the ischium, the obturator internus arises, running backwards and downwards, and terminating by a tendon to be inserted into the rest of the trochanter. The pyriformis originates from the under part of the hollow of the sacrum, and passes out at the sacro-sciatic notch to be inserted with the obturator. These muscles sustain pressure and perhaps injury in difficult and protracted labor, which may explain the uneasiness so often felt in moving the thighs. The coccygeus commences from the spine of the ischium, running posteriorly to be inserted into the side of the coccyx, in order to move and support it. We now see how the pelvis is lined with muscular substance, affording a slight compressible support to the gravid uterus and pelvic viscera. On a parallel with the inner margin of the psoas, along the posterior half of the brim of the pelvis, we find the course of the iliac artery and vein, and encroaching a little when distended on the lateral capacity of the brim. They quit the linea-ilio pectinea at between two and three inches from the symphysis, and, passing over the acetabula, they leave the pelvis with the psoas muscle. The iliac vessels escape pressure entirely during labor, but the hypogastric must in certain positions and sizes of the head sustain pressure.

72. The first, second, and third pair of lumbar nerves, furnish some branches, which, passing out through the substance of the muscles lining the iliac fossæ, supply the upper and outer parts of the thigh; and it is to the stretching and tension of these nerves, especially in the latter periods of gestation, that we must attribute the painful uneasiness which is so often experienced about the pubes, groins, and in the small of the back. So likewise we must attribute to the obturator and crural nerves that weakness and uncertainty of gait which characterises some pregnant women. The lymphatics preserve the same course as the iliac vessels, forming a plexus from Poupart's ligament to the lumbar vertebra. The rectum is by no means an unimportant part of the contents of the pelvis; it is situated at the left side of the projection of the sacrum, and is known sometimes to acquire an immense size from the accumulation of feculent matter, giving rise to very uncomfortable feelings.

On Menstruation.

73. A description of the external and internal generative organs of the female having preceded this article, we shall refer the reader to the treatise on Anatomy, for any information he may require, and go on to notice the important function of menstruation. We do not pretend to throw any new light on the causes of this periodical discharge, with which the health and comfort of the sex is so intimately associated; but we shall endeavour to place before our readers a clear narration of the various circumstances which are found to belong to its healthy and morbid conditions. We are not aware of any change which so much affects the whole course of female life as menstruation. Every process of the female economy to the time of puberty is incomplete and defective, if the menses do not appear; and in after years, when the generative faculties are in exercise, and when the most important functions and duties of female life are to be performed, their health and efficiency are most materially dependent on the regularity and natural character of the menstrual fluid:—and it is equally notorious, when women have passed the middle period of life, and have escaped the dangers incident to parturition, that they may be yet placed in jeopardy, by the final cessation of this function. We believe there is now little difference of opinion as to the nature of the menstrual fluid. That it is not blood seems sufficiently evident from its scarcely possessing one property in common with it, excepting the color; and even here there is not perfect agreement; for, while the coloring matter of the menstrual fluid is permanent, that of the blood is not so. In the London Practice of Midwifery, it is stated that Mr. Brande analysed some menstruous discharge, sent to him by Mr. Money of Northampton, which was collected from a woman with prolapsus uteri, and was consequently perfectly free from admixture of other secretions. It had the properties of a very concentrated solution of the

coloring matter of the blood in a diluted serum. It has been observed that artificial solutions of the coloring matter of the blood invariably exhibit a green tint, when viewed by transmitted light. This peculiarity is remarkably distinct in the menstruous discharge. No globules could be discovered in this fluid; and, although a very slight degree of putrefaction had commenced in it, yet the globules observed in the blood would not have been destroyed by so trifling a change. The menstrual fluid does not soon putrefy, even if exposed to summer heat, nor does it coagulate; and we particularly remember that Mr. Mansfield Clarke, in his lecture on this subject, exhibits a specimen of the menstrual discharge, which has remained in a fluid state for many years. Much more might be said on this point; but we conceive we are fully justified, from what has been already advanced, in defining the menstrual fluid to be a secretion from the uterine arteries, and perfectly different from blood.

74. The age at which menstruation begins varies in different individuals, as well as in different climates. In this country its commencement may generally be dated from the fourteenth or fifteenth year, while in Persia the females advance to womanhood at nine or ten years old; but in Lapland, and the north, puberty does not arrive till the age of eighteen or twenty; and, according to some authors, menstruation in these very cold countries only occurs in the summer season. There is a great variety in the quantity of the discharge; for while in this country from four to six ounces are generally lost at each period, in the east, and in the Archipelago more especially according to Hippocrates, eighteen or twenty ounces of this secretion are thrown forth from the uterus. The time during which women continue under the influence of this discharge is not regulated by any very certain rule. The author of this paper has attended two patients, one of whom invariably continues unwell eight or nine, and the other never more than two days, and yet they are both equally healthy. Writers do, however, agree in considering three or four days as the average time. The commencement of menstruation is generally, though not invariably characterised by attendant indisposition. On enquiry, we frequently find that there are uneasy sensations in the stomach and bowels, distressing feelings of languor and pain in the lumbar and pelvic regions, accompanied by anomalous and hysterical symptoms.

75. These affections may not be immediately succeeded by the discharge; for, in the majority of cases, the health is slightly impaired for two or three months. During one of these seasons of indisposition, when these ailments are perhaps more than usually severe, a serous discharge takes place from the vagina, at first only slightly red, and not becoming entirely sanguineous for several periods. The health continues frequently delicate till the full establishment of this new function; after which, if there be no suppression from exposure to cold or general illness, menstruation may continue to be performed for many years, without any other inconvenience than a slight pain in the back, or trifling hysterical complaints.

76. Nor is this period of female life unattended by alterations, both in character and person, which fully denote that the age of puberty has arrived. The complexion of girls is improved, their countenance is more animated, the tone of their voice more harmonious, their mental powers are much stronger, and they have acquired dispositions and feelings of which they were previously unconscious. The uterus and the vagina are increased in size, the mons veneris is developed and covered with hair, the pelvis is augmented in capacity, and the glandular substance of the breasts, as well as the cellular membrane with which it is invested, is gradually unfolded. Nec minus notum est, quanta virginea alteratio contingat, increscente primum et tepefacto utero; pubescit nempe; coloratior evadit, mammæ protuberant, pulchrior vultus renidet, splendent oculi, vox canora, incessus, gestus, sermo, omnia, decora fiunt.—*Harv. Exercitat de partu.*

77. Although the menses are invariably suppressed in pregnancy, and generally during lactation, their appearance in the latter state is by no means an unfrequent occurrence.

78. The cause of menstruation has greatly exercised the ingenuity of professional men; for while some have attributed it to the influence of the moon, others have supposed it to result from a ferment in the blood, or more especially in the uterus. Dr. Cullen thought that this discharge was not dependent on general but local plethora, and that the uterus was thereby fitted for the healthy discharge of its functions. That the moon exerts no influence in menstruation is evident from the fact that women, and even the same woman, menstruates on every day in the month, without any regard to lunar increase or decline. No part of the anatomical structure of the womb seems to favor the opinion that it may be attributed either to general or uterine ferment; nor are we at all more successful when we look for its cause in universal or local plethora. Were this the case, the quantity of menstrual fluid ought to be influenced by the abstraction of blood from the arm, before or during menstruation, which is not the fact. We were lately particularly impressed with the superior relief of pain afforded only by the commencement of the discharge, to that which we procured by the abstraction of blood in a patient, who was supposed to be suffering under peritonæal inflammation, and from whom under that impression sixteen ounces of blood were abstracted. She had long been the subject of dysmenorrhœa, and in twelve hours after the venesection she became unwell, and the cessation of the pain, which was scarcely relieved by the bleeding, was remarkably manifest and decided. Further than this, women in whom no kind of plethora can by possibility be supposed to exist, who, in consequence of dissipation, have impaired their appetites and diminished their strength, yet regularly menstruate.

79. We believe it to be one of the instances in which the researches of able and intelligent men will terminate in their tracing it to the will of the Creator; in other words, they will regard it as a law of nature, that the fleshy uterus of the human female shall, once every month, by a secretory action, produce a certain sanguineous fluid. If there are some women to whom the menses are

denied, and such instances are on authentic record, nature almost invariably attempts to remedy the misfortune by setting up some other evacuation, which in a measure supplies the place of the proper one, as far as concerns their health. In some we find a periodical discharge of blood from the nose, from the anus, from the puncta lachrymalia, from the ears, or the nipples, and Baudelocque knew a woman of seven or eight and forty who, from the age of fifteen, had been regularly attacked every month by a vomiting and purging, which lasted three or four days. She never had the menses.

80. The penal regulations adopted by the Jewish legislator, and promulgated in Leviticus, and which were afterwards carried out by the physicians of the Arabian schools and their successors, originated the belief that some peculiarly noxious properties were inherent in the menstrual discharge. It is certain that in Holy Writ there are the most precise and authoritative directions as to every circumstance connected with this function; and, supposing them to have no other end in view than the simple prevention of intercourse and the disposal of the secreted fluid, it is not to be wondered at that opinions of its baneful influence should have arisen. In our own times these apprehensions are nearly if not entirely extinct, and in this country women are subject to no restraint or separation during this periodical secretion. Peculiar circumstances, as impaired health and diseased states of the uterus, may render this discharge slightly more offensive and acrimonious than the great volume of the circulating fluid;* but with these exceptions we entertain no other notion respecting it than that it is entirely innocuous.

81. Menstruation is generally supposed to serve the important purposes of maintaining the uterus in a state fit for conception, and during pregnancy of affording nourishment to the child. To the former of these opinions we unhesitatingly subscribe, as we believe every fact in physiology demonstrates the impossibility of conception where menstruation from the uterus does not exist, although there may be vicarious discharges from other parts of the body. Thus far we proceed on certain grounds, and if we remain in doubt as to the precise kind of influence which menstruation exerts on the female system, as a whole, we have no hesitation in believing that it is absolutely essential for the healthy performance of the function of the uterus. The œstrum of animals, when they are salacious, may be regarded as equivalent to menstruation; and, although it is most frequently mucous, yet in very hot seasons and climates it has been frequently observed to be sanguineous.

The latter opinion, that the menstruous blood during pregnancy serves for the nourishment of the fœtus, is not very satisfactory. We find all animals, whether menstruating or not, nourishing the embryo contained in their uteri; and if the whole quantity of menstrual fluid which would have been secreted, supposing pregnancy had not occurred, were bestowed on the fœtus, we cannot suppose that it would contribute very materially to the building up of a child whose weight at the birth is, on an average, from eight to ten pounds.

82. Women generally cease to menstruate in this country from the forty-fourth to the forty-eighth year; the precise time a good deal depending upon the early or late appearance of the secretion. Thus when menstruation commences at ten, twelve, or thirteen years of age, it will frequently disappear at forty; whereas if puberty, the consequence and not the cause of menstruation, has not been established till the sixteenth or eighteenth year, the menstrual discharge may continue till fifty-two or fifty-three, and even later than this. Women, however, seldom bear children in this country after forty-five or forty-six years of age; and thus the propagation of the species, and the active duties consequent thereon, are associated with the most vigorous periods of existence. 'Had any other law prevailed, children might have become parents, and old women might have borne children, when they were incapable of affording them proper nourishment.'

83. It is worthy of remark that the final cessation of the menses is frequently a critical time in female life. Tendencies to disease, and that of the organic kind, for years dormant, may now be excited into activity, and the uterus and mammæ demand watchful attention. The irregularity of the catamenia, and their obstruction for several months, sometimes induces swelling of the abdomen, sickness, and loathing of food. These symptoms resemble pregnancy; and there are some women, as La Motte remarks, who would rather persuade themselves that they are again to become mothers, than that they are growing old, and this persuasion they indulge; 'donec tandem spes omnis in flatum et pinguedinem facesseret.'

84. Dr. Marshall Hall, whose Commentaries on some of the more important Diseases of Females we would especially recommend to all who are interested in puerperal and parturient affections, observes that the general treatment, in regard to the final cessation of the catamenia, involves two points; the restoration of the general health, if this be impaired, and especially the daily observation of the state of the bowels, and attention to diet, air, and exercise; and the second to promote, by every gentle means, the flow of the catamenia when they do appear. The head is frequently requiring attention, as sudden flushes, vertigo, and drowsiness, are common affections at this time; nor can we too forcibly enjoin regular evacuations from the bowels, and the occasional abstraction of blood, by cupping, from the

* Penis cum menstruata concumbentis excoriatur: si novella vitis eo tangatur, in perpetuum læditur: steriles fiunt tactæ fruges, moriuntur insita, exuruntur hortorum germina: si mulier prægnans alterius menstrua supergrediatur, aut illis circumlinatur abortum facit; ei autem quæ uterum non gestat, concipiendi spem adimit, purgantis spiritus, et vapor ab ore, specula atque eboris nitorem obscurat: gustatus hic sanguis canes in rabiem agit, homines vero diris cruciatibus affligit, comitialem morbum, pilorum effluvium, aliaque elephanticorum vitia: idcirco à veteribus inter venena relatus; pari malignitate existimatur, atque sanguinis elephantiaci potus.

De Graaf, p. cxxiv.

back of the neck, not only during the exact period of the cessation of the discharge, but for some time afterwards.

85. Sir Astley Cooper and Dr. Farre have mentioned a case, occurring at this period, in which both the uterus and the mammæ became schirrous in the same subject. The period, says Dr. Hall, including several years before the disappearance of the catamenia, the space occupied by this change, and several years afterwards, may with great propriety be termed the first climacteric period of female life.

86. *Of diseased states of the menstrual secretion.*—It is the opinion of many that women suffer more than men at their approach to puberty; and judging from what we see in this country, where girls are luxuriously educated, often living in warm rooms, and lying on soft beds, we incline to this opinion. We believe there is little dispute as to the greater liability of women to cancer than men, especially at the final cessation of the menses. Notwithstanding these facts, we do think that certain advantages accrue to the sex from menstruation; more especially when discharges of blood are required for the relief of peculiar symptoms and conditions of the system, these are made with the utmost facility through the medium of the menstrual discharge, and not as is too often the case in men, when a vicarious secretion is necessary, with injury to the parts which furnish it. It cannot, however, be denied that the circumstances attendant on menstruation are frequently demanding medical relief, and we propose to consider them in the usual order.

87. *Obstruction of the menses.*—Authors have usually included two forms of disease under this denomination, that in which the menses do not appear at the period of life when they may naturally be expected, or emansio mensium; and that in which, having once appeared, they are suppressed or amenorrhœa. It is right to remark that these terms are frequently indiscriminately employed, and for ourselves we do not see any real distinction between them.

88. Amenorrhœa is a disease of such unbounded variety, and involving to so great an extent, if it be of long continuance, the health and energy of the system, as to preclude our entering fully into its details; we must content ourselves with observing, that it appears in some instances to spring from debility of constitution, while in others it is associated with plethora and florid complexion. The latter form of this affection is by far the most manageable; and, as it is generally more easy to remove that which is redundant than to furnish what may be deficient in the system, so we find in amenorrhœa, arising from fulness of circulation, that by the careful, and perhaps repeated abstraction of blood, by persevering attention to the condition of the alimentary canal, and by the observance of a spare diet, we soon induce the salutary flow of the menstrual discharge.

89. In chlorosis, on the contrary, characterised by pallor and slight tumidity of the countenance, by a quick and small pulse, and by a general exsanguineous state of the system; the treatment is by no means so simple or so quickly successful. The disease may be so confirmed and inveterate, and so mixed up with the affection of different organs, as to render the case truly perplexing. We frequently find, in this form of the malady, that the legs and ancles swell at night, and that the face and eyelids are puffy and distended in the morning.

90. The source of these appearances is œdema; and we know that the interstitial fluid lodged in the cellular substance of the face subsides during the day, the erect posture being generally maintained, and that the cells below are gradually filled again towards night, producing swelling of the ancles. It would be difficult, says Dr. Marshall Hall, to trace the series of causes and effects in the pathology of this affection; but I do think the first cause is in the state of the bowels; that a concurrent cause is the peculiarity of constitution already described; and that an exciting cause is the inactive and sedentary mode of life usually obtaining in female youth. The stomach suffers from its continuity with the intestines, the uterus possibly by contiguous, the head and the heart by remote, sympathies; the pain of the side is peculiar, and too common to be a mere accidental complication; and it therefore probably also depends upon the state of the large intestines.

91. To the symptoms already enumerated, we may subjoin those which arise from derangement of the stomach. Flatulence and capricious appetite are very distressing. The patient is annoyed by an uncontrollable desire for chalk, cinders, and other substances equally unnatural. The bowels are very irregular, sometimes very much confined, and at others in a state of diarrhœa. The breathing is hurried, performed with great difficulty on the slightest exertion, and there is often palpitation of the heart. Cullen says, as a certain state of the ovaria in females prepares and disposes them to the exercise of the genital organs, about the very period at which the menses first appear, it is to be presumed that the state of the ovaria and that of the uterine vessels are in some measure connected together; and, as generally symptoms of a change in the state of the former appear before those of the latter, it may be inferred that the state of the ovaria has a great share in exciting the action of the uterine vessels, and producing the menstrual flux. But, analogous to wha happens in the male sex, it may be presumed that in females a certain state of the genitals is necessary to give tone and tension to the whole system; and, therefore, that if the stimulus arising from the genitals be wanting, the whole system may fall into a torpid and flaccid state, and thence chlorosis and retention may arise.

92. The treatment of chlorosis was formerly conducted upon what may be termed the empirical plan. Specific medicines, called emmenagogues, supposed to exert an immediate influence on the uterus, in compelling it to secrete the menstrual fluid, were given; and very frequently with the smallest success. Blood-letting can very seldom be required in these cases; and we allude to it as we have lately witnessed its bad effects. A chlorotic patient was bled from the arm by her

medical attendant for the relief of difficult respiration, and was partially, of course not fully relieved. It was thought advisable to repeat the bleeding, which was again followed by temporary relief; after this period we saw the case, and nothing could be more conspicuous than its bad effects. Her prostration of strength was extreme; the breathing was more laborious, and an anasarcous state of the body was universally apparent. It is needless to remark that many months elapsed before an opposite plan of treatment was successful in the restoration of the health; and we are sure that events, similar to the one now related, have not unfrequently arisen from the too lavish use of purgatives.

93. We believe that venesection will generally aggravate the evils of this condition; for, while it affords only temporary relief, it will permanently augment the weakness, and the disposition to dropsy. Remedies of the tonic kind, although they may not directly induce the flow of the menses, will certainly where there is pallor of the countenance, with the other indications of debility, facilitate the desired result. Previously to their use some mild aperient, and perhaps a gentle emetic, should be administered. We prefer the preparations of iron to any other remedies of this class, and we have seldom experienced any decided difficulty in their exhibition. Either the sulphate or the carbonate may be employed. The diet should be generous, and wine and water may be allowed. Exercise is very important; and dancing, riding on horseback, or swinging, and country air, will exert a most beneficial influence. The chalybeate waters of our own country will be found a useful auxiliary to other means; and tepid bathing or pediluvia, as well as bathing in the sea, will be of use. Dr. Denman observes that the guides to the ladies contrive to go into the water during the time of menstruation, without any inconvenience. We must remember, in the exhibition of medicine for the removal of suppression of the menses, that there are peculiarities in the constitution of some women, which prevent the good effects of the most approved remedies. Here we are not to be discouraged, but we must call into action other means even if of less general efficacy.

94. All the remedies denominated emmenagogues possess a stimulating property, and their employment is of very doubtful tendency where there is exhaustion, or a large share of debility; if the patient, on the contrary, be plethoric, they are not without danger; for, failing to produce the uterine discharge, they may originate hæmorrhage in some other organ or part. Dr. Home has eulogised the powers of madder root, as a deobstruent in one or two large doses, immediately before the expected period, or in doses of half a drachm twice or three times a day during the interval. Friction of the lower extremities, and electricity, may be strongly recommended. As a local stimulant, and not liable to the objections already urged against constitutional remedies of a similar kind, we must not fail to mention the ammoniacal injection. We have used it many times; and in one or two instances, when the amenorrhœa was of several years standing, we have witnessed its decidedly good effects. It may be employed by adding ℨiß or ℨij of the liquor ammoniæ pur. to twelve or sixteen ounces of warm milk, and throwing up six or eight table spoonfuls into the vagina four or five times daily.

95. *Of menorrhagia, or profuse menstruation.*— Menorrhagiæ, Cullen, cxxxvii. dorsi, lumborum, ventris, parturientium instar, dolores; menstruorum copiosior vel sanguinis, è vaginâ præter ordinem fluxus.

96. This condition of the menstrual secretion is exactly the reverse of amenorrhœa; and if it has existed long, or to any considerable extent, the symptoms are similar to those which are produced by hæmorrhages of any other kind, only excepting the peculiar uterine circumstances with which they are associated. Authors generally describe two kinds of menorrhagia: that in which, by the frequency of return of the menses, a debilitating drain is set up; or when the period is not more frequent than natural, but when the quantity of blood lost at each time (for in excessive flow of the menses or menorrhagiæ the secretion is apt to assume the character of blood) is greater than is compatible with the strength of the patient.

97. We believe this disease most commonly arises from the hæmorrhages which accompany early abortions, or that it is symptomatic of some affection of the uterus itself. It may consist with very different states of constitutional power, either in those who are plethoric, robust, and vigorous, or where there is weakness and partial emaciation. In the one case the undue discharge occurs in consequence of distension or over action, in the other from debility. To whatever extent menorrhagia may proceed, it is invariably accompanied by indications of uterine irritation, such as pain in the back and loins, and about the pelvis, nor do the uncomfortable symptoms stop here: if there be frequent returns of the hæmorrhage, the general health suffers, the loss of strength is very manifest, dyspepsia harrasses the patient, leucorrhœa occurs in the intervals, and the foundation is laid of visceral disease, and eventually of dropsy.

98. Burns says that the causes giving rise to menorrhagia may be divided into those which occasion the two predisposing states of plethora and weakness of the vascular system, and those which act more immediately on the vessels of the uterus. Of the first kind, may be mentioned those which on the one hand increase the quantity of blood, as rich diet, indolence, &c.; and, on the other, debilitate the body, as fatigue, abstinence, and profuse discharges.

Amongst the exciting causes, or those more particularly affecting the uterine vessels, may be mentioned the excitement produced by costiveness, or dyspepsia, and that morbid condition of the womb occasioned by abortion, or laborious parturition.

Married women are most liable to menorrhagia; frequent parturition or undue lactation being a powerfully predisposing cause. We are now in attendance on a lady who, in opposition to advice, has persevered in nursing fifteen months with health gradually declining; for the

last half year she has regularly and rather excessively menstruated; but it was not till the weaning was fully accomplished, that any profuse hæmorrhage occurred; immediately on the completion of the process, the uterine vessels, weakened by the drain of long continued lactation, poured forth a large quantity of blood. A repetition of this hæmorrhage has prostrated her little remaining strength, and months will be required to restore her health.

99. The treatment must of course vary with the degree, and the longer or shorter continuance of the disease. The recumbent position, abstinence from stimuli and every kind of exertion, and perhaps, in the very commencement, venesection, will suffice for the removal of menorrhagia, where it is slight and connected with only an occasional feverishness of system. We must prohibit the use of animal food, and preserve an aperient, not a purged state of the bowels, by the infusion of roses and sulphate of magnesia. These measures will generally suffice for the removal of the simplest kind of menorrhagia; but when it is more severe we must resort to local measures, as the application of cold to the pudenda and loins, and, if necessary, the injection of styptic and astringent lotions into the vagina. There are cases, not of very unfrequent occurrence, in which astringent injections, and even cold water, cannot be borne, as they not only produce uncomfortable and painful sensations, and occasionally inflammation of the vagina and uterus, but manifestly increase the discharge. Here we must trust almost entirely to constitutional measures. Digitalis, in an excited state of the circulation, has been productive of great good; but the propriety of not lowering the patient, beyond the point absolutely required for the restraining of the hemorrhage, will be apparent to all.

100. We might enter more at length into the treatment of excessive and consequently highly dangerous cases of menorrhagia; but as some authors think that instances of this latter kind, in which the blood poured out coagulates, ought to be regarded as hæmorrhages from the uterus, rather than menorrhagia; and, as we intend fully to describe the treatment to be observed in uterine hæmorrhage, we shall refer our readers to that part of this treatise for the desired information; and shall conclude the remarks on profuse menstruation by a review of the measures to be adopted, in the intervals of the menstrual periods, to prevent the return of the disease. To effect this purpose a mild and nutritious diet, country or rather the sea air, chalybeate water, and the injection of astringent washes into the vagina, will do much. In addition, all painful exertion, or rather every degree of exercise which exceeds the limits of comfort, by inducing fatigue, should be avoided. We must however bear in mind that in cases where the weakness giving rise to menorrhagia is local, not constitutional, we incur some degree of hazard by the employment of general tonic measures, as we are told that by these means we increase the strength of both parts at the same time. We confess we are not very fearful on this point, if due care be displayed in the treatment of the local debility: let cold astringent injections be perseveringly thrown into the vagina, at the same time allowing the general health every opportunity to recruit, and we feel assured that greater benefit will be obtained than if we had carried forward the treatment by a preponderance in favor of local, to the disregard of constitutional remedies.

101. It is scarcely necessary to remark that long continued menorrhagic discharge gives rise to very complicated affections of the general health, in which almost every organ seems to suffer. Here we may exhibit, having previously regulated the state of the bowels, the sulphate of iron, or the sulphate of quinine, in small repeated doses.

102. *Dysmenorrhœa, or painful menstruation.*—This disease is not of very unfrequent occurrence, especially in cities and large towns, where dissipated and irregular habits so generally prevail. If the menstruation be painful it is generally very sparing, at least for the first two or three days, till by the influence of remedies the cause of obstruction is removed. It is most probably dependent on an imperfect or partially established catamenial action; an opinion supported by the beneficial results of mild emmenagogues; and by a knowledge of the way in which the discharge comes on. The approach to the period is characterised by continued and severe pain in the lumbar, dorsal, and pelvic regions, which is tardily followed by a very slight flow of the secretion; this, as we have just now observed, continues imperfectly for the first few days and, as the discharge increases in quantity, the pain becomes less severe, till at last it is scarcely regarded. We attended a lady three years ago, in dysmenorrhœa, where there was superadded to the disease the most violent spasm of the intestines we ever recollect to have seen; it was not uncommon for her to remain delirious for some hours from the violence of the pain. Opium, sinapisms, and the warm bath, gave slight and temporary relief: but it was not till the employment of the ammoniacal injection with opium, continued through many periods, that she was permanently improved. This patient resides in the West of England, and we have lately heard that her menstruation is performed with very trifling pain, and so abundant in quantity as to free her from congestion about the head, formerly one of her most distressing symptons. The remedies we have now mentioned are to be resorted to during the attack, and the opium is particularly beneficial, if combined with ipecacuanha, and given in such doses in tepid diluents as to produce perspiration.

The interference with the general health must be treated on general principles, ever taking care to prevent any accumulation in the alimentary canal, by the judicious exhibition of laxatives.

103. Having concluded our general remarks, we subjoin the following observations on menstruation.

104. All the common circumstances, as Dr. Denman observes, attending menstruation, have been well and fully described by various authors; but having very often observed a substance expelled with the menstrual discharge, which has hitherto escaped notice, and apprehending the

knowledge of this substance may be of use in practice, he felt it incumbent to describe it.

105. In the examination of that discharge, for the purpose of investigating the state of the uterus, and the discovery of some complaints thereon depending, a membranous substance was often shown me, which was usually considered as the token of an early conception, or as the casual form of coagulated blood. But, on examining this substance with more attention, I constantly found that one surface had a flocky appearance, and the other a smooth one; that it had in all respects the resemblance of that membrane which Ruysch had called the villous, of the formation of which Harvey had given a very curious description, and which the late Dr. Hunter described with his usual precision and called the decidua. To put the matter out of doubt, several years ago I requested the favor of Dr. Baillie to examine some portions of this membrane, and he agreed with me in thinking it an organised membrane, similar in structure to the decidua. As the first cases in which this membrane was discharged were those of women who were married, a doubt arose in my mind whether it was not really a consequence of early conception; but I have lately had the most undoubted proofs that it is sometimes discharged by unmarried women, and may be found previously to and without connubial communication; and that the uterus has occasionally, or constantly in some women, the property of forming it, at, or in the interval between the periods of the menstrual discharges. It seems particularly necessary to establish this fact, as the appearance of the membrane has more than once given rise to erroneous opinions and unjust aspersions. Nor is this the only circumstance in which some women, at each period of menstruation, have symptoms like those which accompany pregnancy or parturition. In every case, in which this membrane has been discharged, the women have menstruated with pain, and the discharge has flowed slowly, and apparently with difficulty, till the membrane was come away, which in some cases has been in small flakes, and in others in pieces equal to the extent of half the cavity of the uterus, or more, of which they retain the shape. I suspect, but my experience does not enable me to decide, that this membrane is expelled in every case of habitually painful menstruation.

106. Morgagni (vide Epist. xlviii. Art. 12) describes this disease very accurately. The membrane, he says, is triangular, corresponding to the shape of the uterine cavity; the inner surface is smooth, and seems as if it contained a fluid; and that it does so I have no doubt, from my own observation; the outer surface is rough and irregular. According to Morgagni, the expulsion is followed by lochial discharge.

107. Dr. Denman supposes that no woman can conceive who is affected with this disease; but some cases, says Mr. Burns, and amongst others that related by Morgagni, are against this opinion. Mercury, bark, chalybeates, myrrh, and injections, have all been tried without much effect. Time in general removes the disease better than medicine, which is only to be advised for the relief of pain, weakness, or any other symptom which may attend or succeed to this state.

PART II.

OF THE GRAVID UTERUS.

108. Having completed the first division of our subject, in which we have endeavoured to present to our readers a practical rather than an elaborate abstract of the obstetric properties of the female pelvis, including the natural and diseased conditions of menstruation:

109. We shall proceed to the description of the gravid uterus, comprising in this section the changes induced in the uterus and its appendages by impregnation, the various uterine products of conception, the doctrine of conception itself, and the diseases of pregnancy, together with its earlier and later signs. Here we shall pursue the same course as in the former part of the treatise, disencumbering the subject as much as possible of all irrelevant and unimportant details, and concentrating the attention of our readers on those facts and symptoms which are independent of controversy, and which lead to useful results in practice.

110. It is scarcely necessary to observe that the whole genital system of the female undergoes most important changes from impregnation; and, in treating of the gravid womb, we shall principally dwell on the alteration in its volume, in its figure, in its structure, in its situation, a d in the action of which it becomes susceptible.

111. The uterus, in its gravid state, contains the ovum, which consists of the fœtus and its appendages, viz. the placenta, the membranes, the funis umbilicalis, and the liquor amnii. It will hence be apparent, on the slightest reflection, that the properties of this viscus, at the close of pregnancy, must differ very widely from those by which it is characterised at its commencement, or during its unimpregnated condition.

Its volume and weight are conspicuously increased; so that the uterus, which before pregnancy attracted no notice from its size, and produced no unpleasant effects from its weight, is now most prominent from its increased volume, and is giving rise to troublesome symptoms solely by its augmented gravidity. Its enlargement is more apparent in the latter than in the earlier months of pregnancy; although this remark is true only with regard to its absolute increase, as in the first month after conception it probably doubles its natural size. It does not go on in this ratio, not being twice as large in the ninth as it is in the eighth month. The uterus increases in every direction during pregnancy, yet all its diameters do not increase in the same proportion in every period, and hence arises its alteration in shape. The longitudinal axis of this viscus increases much more from the third to the sixth than from that to the ninth month; whilst the other dimensions augment much less in the earlier than in the latter periods, when the cavity grows rounder in all parts: not, however, entirely losing that oval figure which is natural to it in the unimpregnated condition.

112. The position of the uterus is much

changed during pregnancy; and it is of great moment to be well informed on this point, as we may be called upon to distinguish between pregnancy and ascites, schirrous or dropsical ovaria, or any other abdominal intumescence; and the right surgical operations for the relief of these morbid conditions will depend on the correctness of our diagnosis.

113. It is not necessary here to enumerate the various marks on a knowledge of which will depend the truth of our opinion. These have been already alluded to, and they will hereafter be dwelt on more fully. The os uteri, at the close of pregnancy, is situated inferiorly and posteriorly, pointing towards the middle of the sacrum; the fundus is anteriorly beyond the point of the ensiform cartilage; having above posteriorly, and at its sides the intestines, and below and in front the bladder when distended. The ascent of the uterus is never directly upwards, but generally inclining a little to one or the other side, and, according to Hamilton, most commonly to the right. Three causes may be adduced as giving rise to conspicuous deviation in the position of the uterus. The relaxed condition of the abdominal parietes, generally if not always increased by child-bearing; the boldness of the lumbar curve, by which the womb is thrown unnaturally forward, and deformity of the pelvis. The accoucheurs of the last century, and especially Deventer, ascribed to the relaxed condition of the abdominal parietes the obliquities, as he termed them, of the uterus, to which he erroneously imputed the interruption of labor; overlooking the two last-mentioned causes, to which he might with propriety have attributed most of the obstacles to parturition.

114. While the uterus is thus altered in its figure, position, and volume, by pregnancy, it does not suffer less change in its composition and development. 'Its fibres not only unfold and lengthen during this state, but they become soft, red, and spongy, till at length we recognise in them all the appearances of muscular organisation.' Blumenbach, and some of the continental anatomists, have denied the muscularity of the uterus, principally from their not being able to discover such structure in its unimpregnated state. We cannot concur in such an opinion. In the mammalia generally the womb is indisputably muscular; and, in the womb of the rabbit, there are two distinct sets of fibres, annular internally, and longitudinal without, the action of which, in a rabbit whose abdomen was opened at the close of pregnancy, we have seen more distinctly than the peristaltic action of the intestines. In the impregnated uterus the muscularity of its structure is obvious, as many preparations in our various museums will testify. Like other structures of the same kind, it is acted on by specific stimuli, the ergot, the distension produced by the child at the full period, the presence of the placenta, and by the accidental remaining behind of a clot of coagulated blood. Allowing these facts their full weight it is, to say the least of it, opposed to the simplicity of nature, so apparent in all her operations, to deny the muscularity of the human uterus, especially when strengthened, as we have already observed, by the established knowledge of its irritability and power of contraction. Anatomists are not agreed as to the regularity of the course of these fibres. Ruysch, and Dr. Hunter in his splendid work on the Gravid Womb, describe them as transverse in the body of the uterus, but forming at the fundus concentric circles around the fallopian tubes.

115. The ligaments of the uterus, the ovaria, and the fallopian tubes, are not, towards the close of gestation, situated as formerly, loose in the pelvis; for the duplicatures of the broad ligament, in which they are contained, are now spread over the womb; and these parts are necessarily confined by the stretched peritonæum. The blood-vessels are much enlarged during pregnancy, especially in the part occupied by the placenta, where some of them are dilated in a surprising degree. The capacity of the veins is so much increased that they have sometimes received the name of sinuses, and, in the part occupied by the placenta, many of them are large enough to receive a goose's quill. Nor is it these vessels alone which are so developed; the lymphatics are much more so when we consider their original diameters. Cruikshank says they become as large as quills, and are so numerous in the latter periods as almost to induce the belief that the uterus is nothing but a composition of these vessels. The nerves participate in this increase of development; and, when we consider the numerous sources of their origin, we cannot wonder at the sympathy of so many parts with the uterus, or at the variety of symptoms produced by the diseases which affect it.

116. There has been much controversy about the increase of thickness in the gravid uterus; some affirming that its thickness was greatly augmented, while others have strenuously denied the fact, and have stated that it is even thinner than in its virgin condition. If its parietes do not preserve all their natural thickness, while it is acquiring a larger capacity, at least they lose so little of it that many authors have thought it remains the same in all periods. We are not aware of any facts which enable us to speak with absolute certainty on this point; as we have seen, in the obstetric museum of Guy's Hospital, four preparations of the pregnant womb, which demonstrate its thickness and thinness in an extraordinary degree.

117. Denman says that, if healthy, it retains its original thickness through the whole period, to whatever degree it may be distended. He also considers this thickness the medium of its strength, by which it is capable of exerting infinitely greater power for the expulsion of its contents than the uterus of any animal. If the womb be increased in thickness there is no practical deduction of importance connected with it; if on the contrary it be extraordinarily attenuated it is evident that especial caution should be employed in the performance of any manual or instrumental operation within its cavity; as rupture and laceration are accidents of not very rare occurrence. The place where the placenta is attached is that where the thickness of the parietes is most considerable, and the vicinity of the orifice is the thinnest part. To

judge as correctly as possible, on this point, our examination should be made when the uterus is in its state of greatest dilatation, or before the waters have passed off; for the thickness will of course increase in proportion to the diminution of its contents.

118. Little need now be said as to the nature of the uterine enlargement; that it is not owing to mere mechanical distension is, we conceive, sufficiently proved by what we have already advanced: we must attribute it to the gradual and increasing development of all the structures entering into the composition of the womb, and also to the very large quantity of blood which is circulating through its vessels. It is accompanied by real growth, and by the accretion of cellular substance.

119. The follicular apparatus about the neck of the womb, as it serves the important purpose of protection to the membranes from any foreign body, is deserving of notice. During the whole period of gestation these glandular follicles secrete a viscid gelatinous fluid, closing the mouth of the uterus, and rendering it impervious after conception. It is from this source that the glairy fluid, at the commencement of labor, denominated show, is principally furnished.

120. Thus pregnancy is not only giving rise to changes in every part of the original structure of the uterus, and which become more apparent as gestation draws towards a close, but at the time of labor we find a new principle superadded, for the purpose of putting a stop or termination to the further ascent and enlargement of this viscus. It is this principle which gives a disposition to the uterus to act upon, and to exclude, whatever is contained in its cavity; and, if any further proof were wanting of its muscularity, the way by which it thus rids itself of its contents would abundantly furnish such testimony. This action has been considered as of two kinds; tonic action, which is equal and constant; and spasmodic contraction, which is sudden and transitory, and is that species of power which is called into exercise by the exigencies of parturition. Perhaps the more simple and correct statement is that which represents both these species of action as the same in their nature, differing only in their degree; this difference being produced by the large volume of contents upon which the womb has to act, and which oppose such various degrees of difficulty and resistance to the completion of its purposes, as to render necessary such contractile efforts as must be attended by spasmodic and painful sensations.

121. Various opinions have been entertained by physiologists as to the precise nature of the uterine action, but we are not aware of their having arrived at any satisfactory result. The original or genuine cause of its action may exist in its structure, form, or properties, or perhaps in some inexplicable impression produced on the uterus by the child. The circumstances of the constitution, as its strength and disposition to act, and more especially the blood, appear to exert an important influence as to the manner in which the effects of uterine action are produced.

122. The prevailing opinion is that which we have already stated, that the action of the muscular fibres of the uterus very nearly resembles that of other parts, and that the pain peculiarly attendant on its exercise arises principally, if not solely, from the obstacles it has to surmount, and which are inseparably connected with human parturition. Amongst the most conspicuous of these obstacles may be enumerated spasm, the firmness of the os uteri, and the resistance of the perineum and vagina. Having now presented a brief, but we hope a sufficiently explicit view of the womb and its contents generally, at the termination of pregnancy, we shall pass on to notice in the same manner the principal circumstances connected with the expulsion of these contents. Immediately after the rupture of the membranes, and the passing off of the waters, a new series of action is commencing in the womb, and the very reverse of that power, which during the period of gestation has been incessantly employed in building up the uterine structure, is now called into exercise to carry back the uterus, as far and as quickly as is consistent with the uniform perfection of nature's operations to its original unimpregnated condition. The same contractile effort which ruptured the membranes, having acquired fresh force by the removal thus far of the obstacles which opposed its exercise, acts with increased power upon the remaining portion of the uterine contents, and soon completes the work of their entire expulsion. It is natural to suppose, what is really the case, that after such extraordinary efforts the whole system, but more especially the uterus, remains for some little time torpid and exhausted; this condition, if the labor has been favorable, as to its severity and continuance, is but of short duration; and on examination of the uterine region, very soon after entire delivery, we are surprised at the collapse which the uterus has undergone: for instead of a womb considerably larger than the adult head, occupying the greater part of the abdominal region, we find a hard, round, firm body, scarcely as large as the fœtal cranium, occupying a situation a little above the ossa pubis. This, although the most prominent and desirable event, and that which is most frequently occurring after a well managed labor, is not the only one which demands our strict and anxious attention. The vagina, whose parietes have been greatly distended by the passage of the child, is longer in recovering so much of its original dimensions as places it beyond the reach of any untoward accident. Its laxity is such as to admit very easily of insertion, more especially, if any injudicious attempts have been made to extract the placenta, by pulling at the funis. Inversion of the uterus may be produced by the same cause, and, whenever any degree either of instrumental or manual force has been employed in the labor, it is highly important that we should satisfactorily assure ourselves that all is right. This is best effected by laying the hand above the symphysis pubis, not removing it till we have grasped and distinctly felt the uterus.

123. Another method may be practised with extreme caution, which consists in passing up two or three fingers into the vagina; when, if there be any great degree of inversion, either

of the vagina or uterus, it will easily be ascertained. We would here deprecate the indiscriminate practice of thrusting the whole hand into the uterus, on slight occasions, as replete with danger of the worst kind; nothing justifies the introduction of the hand, excepting cases of extreme hazard and difficulty. It will be sufficiently evident, after what has been already stated, as to the great enlargement or development of all the structures of the uterus, that, even where nature's intentions with regard to the contraction of this viscus shall have been fully answered, its blood-vessels must necessarily remain for some time of large capacity. The vessels which during pregnancy have been shooting from the uterus into the placenta, are, as we have already said, of very large size, and it is only by the contraction of the muscular fibre of the uterus around them, which ties them up, as by a ligature, that they are rendered secure. Hence the increasingly great importance of procuring this contracted state of uterus, which is without doubt the only permanent safeguard against hæmorrhage. External pressure, carried to the extent of griping the uterus, with the administration of cold, either externally or internally, or both, are amongst the most efficient measures. We need scarcely add that any circumstance calculated to give impulse to the circulation, whether of a mental or physical kind, ought most sedulously to be avoided.

124. The next object of our enquiry will be the womb during gestation; and here we shall dwell a little more in detail on those circumstances which by their gradual development have produced the results already described. Though we do not perceive very clearly what passes in the uterus at the instant of conception, and although we are not very sensible of its enlargement in the first months of pregnancy, it may be assumed, as a fact beyond all controversy, that the womb does possess this principle of gradual growth; and so large does it become, in the latter periods, that our greatest difficulty is in conceiving how its vast increase of size has been accomplished. For the first two or three months the uterus suffers little alteration in its shape, its cavity remaining, as before impregnation, pretty much of a triangular figure. Its weight, however, is increased after conception; and one of the first effects produced is its subsidence rather lower into the vagina, the shortness of which has been considered one of the equivocal signs of pregnancy. The uterus, thus confined within the bony cavity of the pelvis, has a natural tendency from its increasing bulk to gravitate downwards, which satisfactorily accounts for many of the distressing and troublesome symptoms of which women at that period complain. The fundus uteri is the part first distended; and, notwithstanding the increased weight, after a certain time begins to ascend. About the fourth month the uterus may be manifestly felt above the brim by applying the hand to the hypogastric region. In the fifth it is midway between the pubes and navel; in the sixth it is a little below, and in the seventh a little above the navel. In the eighth it is half way between the scrobiculus cordis and umbilicus; at the ninth it has reached the ensiform cartilage or scrobiculus cordis; and, at the commencement of labor, it is frequently not much higher than during the seventh month. In the second month the uterus is enlarged in every part, without much change of shape; at the end of the third month it generally measures from the mouth to the fundus above five inches, one of which belongs to the cervix; in the fourth it measures five inches from the fundus to the beginning of the neck; in the fifth about six inches from the cervix to the fundus. In two months more it measures eight inches; and in the ninth month it generally measures ten or twelve inches, and is oviform in its shape.

125. In the fifth month the cervix uteri begins to stretch, and one quarter of its length has become distended. In another month one half of the cervix is suffering this change; and in the eighth the neck is completely effaced, and its orifice is as high as the brim of the pelvis.

126. The changes of the os uteri are principally effected during the ninth month, when its lips shorten, and sometimes disappear, although more generally they continue to project a little until labor commences. The mucous follicles too become more developed, and they pour out a fluid which serves the purpose of lubricating the parts and giving the first pretty certain indication of labor.

127. The *umbilical cord* is the channel of communication between the mother and the child, and is passing from the abdomen of the latter to the placenta, into which it is generally inserted about one-third from its edge. It consists of two arteries, continuations of the arteriæ hypogastricæ, and one vein protected by a membranous coat, the space between the vessels being filled up by a glutinous nucleus. It is worthy of remark that neither absorbents nor nerves enter into the composition either of the funis or placenta, and that the funis under various modifications is found not only in oviparous and viviparous animals, but also in plants. The course of these vessels is not always straight; they run sometimes in a spiral direction, the arteries coiling round the vein, both chorion and amnion entering into the composition of the sheath, 'the chorion adhering firmly to the cord every where, but the amnion not adhering to the chorion; it is not even in contact with it at the placental extremity, but forms there a slight expansion, which from its shape has been called by Albinus the processus infundibuliformis.' *Burns*, p. 143.

128. For some weeks after conception, if the embryo be examined, no trace of the umbilical cord can be perceived, the abdomen of the child firmly adhering to that which afterwards becomes the placenta. This bond of union, by its subsequent extension, is converted into the funis umbilicalis, the length and thickness of which are not always in proportion to the size of the fœtus. The length of the cord varies greatly in some cases, being double the length it is in others; and, in a twin labor we once attended, it was so preternaturally short as scarcely to allow sufficient space for the application of the ligatures. Its average length is two feet, although the range of variation is from six inches to four feet.

129. The funis is sometimes knotted, and in a case we lately attended we counted five distinct knots, but there was no diminution in the size or vital powers of the child. The varicose state of these vessels is said sometimes to interfere with the circulation and growth of the child, and even to destroy it altogether: this we do not doubt, but we have frequently met with this varicose state of the cord entirely unaccompanied by these circumstances. Sometimes by the rupture of the vessels blood is poured into the uterus, exciting pain and a sense of distension.

130. This, however, is only known when the membranes are ruptured by the discharge of coagula. If the fœtal and maternal portions should communicate, the mother is weakened and may even faint, and in every instance the child suffers but does not always die. *Vide Bandelocque l'Art.*, note to section 1084.

131. In a case which occurred to us some time since, where the cord was very much twisted round the neck, body, and thighs of the child, we divided it in preference to any attempt at untwisting. The latter measure we feel convinced, had it been ever so carefully performed, would have ruptured the funis. The shoulders of the child had here been delayed twenty minutes after the expulsion of the head, and we are persuaded the birth could not have occurred, unless the placenta had accompanied or immediately followed the child; or that such pressure, prior to its expulsion, would have been made on the cord as to have destroyed its life, if the funis had not been divided; of course the fœtal portion of the funis was instantly secured by ligature, and the shoulders were seen in the world. Burns, in a quotation from M. Anel, says the cord may, by a fall or violent concussion of the body, be torn at a very early period of gestation. In this case the child dies, but is not always immediately expelled. It may be retained for several weeks; afterwards the ovum is thrown off, like a confused mass, enclosing a fœtus, corresponding in size to the period when the accident happened. The cord may be filled with hydatids.

132. Mauriceau proposed, where the cord was unusually thick, that two ligatures instead of one should be applied on the portion which remains attached to the child, as it may so happen that by the shrinking of the cord a fatal hæmorrhage may ensue.

133. *Placenta.*—There can be no doubt, notwithstanding our ignorance of the precise manner in which the functions of the placenta are performed, that it exerts a most important influence on the vitality of the fœtus. Changes, analogous in some degree to respiration, are required by the fœtal blood, and these it receives by its circulation through the placenta; and, although we cannot trace the connexion between its maternal and fœtal portions, yet we know, if the placenta be injured by the rupture of the vessels passing between its inner surface and the womb, the child being deprived of its proper blood would perish, while the mother might experience no very serious injury.

134. The human placenta is a circular flat body, about six inches in diameter, and one in thickness. In quibusdam placenta reperitur crassior, amplior, et sanguine abundantior.—Harv. The centre is generally its thickest part, from which to its circumference it is gradually attenuated, so as to lose itself in the involucra or membranes.

135. The shape of the placenta varies, being sometimes oblong, and at others curiously lobulated; and we lately met with an example of the termination of the umbilical cord in the membranes at a very short distance from the placenta. The human placenta appears to consist of blood vessels and a cellular web (placentæ substantia non constat glandulis sed mirè vasculosa est.—Ruysch), but possessing neither absorbents nor nerves. Dr. Haighton used to consider it as made up of three systems, the maternal or cellular, in which the arteries terminate, and the veins commence; the fœtal or vascular; and the intermediate, consisting of pulpy or cellular substance, and in which, if they exist, are to be found the communicating vessels between the maternal and fœtal portions. If we throw ever so fine an injection into the umbilical arteries of the fœtus, we shall thereby distend a considerable part of the placenta, but we shall find that the vessels of the maternal portion receive no part of the injection. On the contrary, if we inject from the uterine arteries, we shall again distend the placenta, but we shall find the umbilical vessels and their ramifications perfectly uninfluenced. Hence we may infer the separation of the two portions of this viscus. It is also admitted that the blood of the fœtus, with regard to its formation, increase, and circulation, is totally unconnected with, and independent of the parent, except that the matter by which the blood of the fœtus is formed must be derived from the parent. Abundè me demonstraturum arbitror, viviparorum quoque fœtum, dum adhuc in utero continetur, non matris sanguine nutriri spirituque ejus vegetari, sed animo viribusque suis frui, ut pullus in ovo solet proprioque sanguine gaudere. *Harv. Exercitat.* xxxiv.

136. Thus in all probability, analogous to the adult circulation through the lungs, the blood fitted for the fœtal circulation is deposited by the uterine arteries in minute vessels or cells, situated in the intermediate portion of the placenta, where the ramifications of the umbilical vein, either by a secretory process or by actual absorption of some of its finer parts, take up that which is necessary to the well-being of the fœtus, and convey it along the funis to its ultimate destination. In like manner, when the circulating fluid of the fœtus requires any change, it is returned by the umbilical arteries of the funis to the cells of the placenta, whence the placental veins reconvey it to the general circulation of the parent. From all this it appears that Harvey was not far from the truth when he promulgated the opinion of the placenta performing the office of a gland, and secreting from the blood brought by the maternal arteries that which is necessary for the nourishment of the fœtus, much after the manner of the breasts and the liver. Ego itaque placentæ et caruncularum tale munus existimo, quale hepati atque mammis vulgo tribuitur: hepar nempe chylum ex intestinis haustum cor-

pori alendo ulterius præparat: et placentæ similiter succum alibilem à matre provenientem nutriendo fœtui porro concoquit.—*Harvey de Placentâ.*

137. *The membranes.*—Great diversity of opinion has obtained in relation to the number and structure of the membranes, which, together with the placenta, contain the fœtus, the navel string, and the liquor amnii. This has principally arisen from the different periods of gestation when they were examined; and from the confusion of terms and the variety of descriptions which have been annexed to them. It does not appear very important, for practical purposes, to enter into a lengthened examination of the time when the membranes become consolidated or adherent one to the other; and we shall, therefore, describe them as they are found in the latter months of pregnancy; consisting of the amnion, and true chorion, and the decidua or spongy chorion; which last is furnished entirely by the uterus, and serves for its connexion with the vessels of the fœtus.

138. The ovum, says Mr. Burns, when it descends into the uterus, consists of two membranes, one within the other, having very transparent jelly interposed between them; but in process of time the innermost, which is called the amnion, grows so much faster than the outermost, called the chorion, that it comes in contact with it, or at least has only a thin layer of jelly interposed. The amnion is transparent, and thinner than either of the two other membranes, although, at the termination of pregnancy, it is stronger than either; it adheres to the internal surface of the chorion and placenta, and, being reflected over the funis, it terminates at the umbilicus.

The decidua, as we have already observed, is provided entirely by the uterus; it is not a covering of the fœtus, but the lining of the womb falling off after delivery, and generally discharged with the lochia. Ruysch remarks that these membranes, in the advanced state of pregnancy, cohere slightly to each other; though, in some ova, there is a considerable quantity of fluid collected between them, which, being discharged when one of the outer membranes is broken, forms one of the circumstances which have been distinguished by the name of by or false waters. Haller supposed that the decidua was formed by the uterine vessels. Dr. Hunter thought the decidua originated in coagulable lymph. John Hunter attributed its formation to coagulated blood, forming a pulpy substance on the inner surface of the uterus.

139. Burns says that the decidua consists of two layers, one is highly vascular, proceeding directly from the uterus; the other, which is most probably formed by these vessels, is more fibrous and gelatinous; and, when this is removed, the primary vessels or outer layer may be seen like a fine efflorescence covering the surface of the uterus. In some cases the decidua extends a little into the fallopian tubes; in other instances it does not. In no case does the cervix form decidua. It is only produced by the fundus and body of the womb, and immediately above the cervix the decidua stretches across so as to form a circumscribed bag within the uterus. In some instances we have observed this continuation to be wanting, although the parts were opened with ease. In all other circumstances these uteri resembled those where the decidua was continued across; but perhaps, notwithstanding this, there may have been a difference of two or three days in the period of impregnation occasioning this variation. In every case the decidua, consisting of two layers, is completely formed before the ovum descends. When the embryo passes down through the tube it is stopped, when it reaches the uterus, by the inner layer, which goes across the aperture of the tube, and thus would be prevented from falling into the cavity of the uterus, even were it quite loose and unattached. By the growth of the embryo, and the enlargement of the membranes, this layer is distended, and made to encroach upon the cavity of the uterus, or, more correctly speaking, it grows with the ovum. This distension or growth gradually increases, until at last the whole of the cavity of the uterus is filled up, and the protruded portion of the inner layer of the decidua comes in contact with that portion of itself which remains attached to the outer layer. We find, then, that the inner layer is turned down and covers the chorion, from which circumstance it has been called the reflected decidua. Thus we see that wherever the ovum descends it is encircled by a vascular covering from the uterus, which unites in every point with those shaggy vessels which sprouted from the chorion, and which made what was called the spongy chorion. One part of these vessels forms the placenta, and the rest gradually disappear, leaving the chorion covered by the decidua. The liquor amnii, or the waters, as they are denominated in labor, are generally transparent, though they are sometimes of a dusky brown color. They are contained, as the name implies, within the bag of the amnion, and, when analysed, they yield principally water, with a small proportion of mucus, saline matter, and earth. This fluid serves several important purposes in pregnancy; it furnishes a yielding and easy support for the fœtus in utero in the early months; it protects the fœtus from any mechanical or spasmodic contractions of the womb; and in the latter months it equally preserves the uterus from the plunging and kicking of the child. It allows of easy motion within the uterine cavity, gently distending it, and preventing any morbid adhesion of its parts. In the time of parturition every practical accoucheur is aware how much more quickly the os uteri is dilated by the membranes forced down in the form of a cone than by any part of the child's body.

On Conception.

140. We do not intend to lay before our readers even a small part of what has been said and written on this wonderful and difficult subject; but, as a treatise on obstetric science would be incomplete without a slight view of the different opinions respecting generation, we shall, as briefly as possible, detail some of the theories which have prevailed in the different ages of the world, premising our obligation to Dr. Denman for the materials of th

sketch. With him we believe that the first part of the process by which primordial existence is established, from the minuteness and complication of the objects to be described, and, from the retirement of the attending circumstances, is probably involved in too much obscurity to be discovered.

141. In reference to this subject we cannot deny ourselves the pleasure of quoting literally the following passage from Denman's Introduction to the Practice of Midwifery, p. 105:—'Through all nature there is not found a single body which consists of materials lying in confusion. However small, and apparently insignificant, every particle exhibits proof of the majesty and wisdom of God; and it may be presumed that the minutest elementary parts of every substance are originally composed and wrought up in the most regular order into what is called form; yet, in mineral substances, it is a form so immerged in matter, that it is ever restrained from the acquisition of the excellence of a living body, unless there be a previous destruction of its present form; but the more refined the matter the more perfect is the form, and the more perfect the form the more exquisite are the properties. Hence the common observation seems to have been made of the encroachment, as it may be called, of one order of natural bodies upon another; of the near accession of the finest minerals to the lowest vegetables, and of the first vegetables to the lowest animals, in such a manner that they can scarcely be distinguished.'

142. Impregnation may be defined that function whereby the seminal fluid, applied to the female genital organs, excites the various generative actions, thus ultimately producing the fœtus. Pythagoras supposed that, from the brain and nerves of the male, a moist vapor descended in the act of coition, from which similar parts of the embryo were formed; the grosser parts were composed of the blood and humors contained in the uterus, and, according to the laws of harmony, seven, nine, or ten months were required for the perfection of the fœtus.

143. Empedocles thought that some parts of an embryo were contained in the semen of the male and others in that of the female, and that, by the mixture, the embryo was formed. He was likewise of opinion that the desire of procreation originated in the natural tendency of the separated parts to be united.

144. Hippocrates approached very nearly to this view of the subject, maintaining that conception took place in the cavity of the uterus by the admixture of the male and female semen; both of which contained the organic principles of the embryo.

145. Aristotle, forgetting that menstruation is not common to all animals, who nevertheless propagate themselves, denied the existence of semen in the female, imagining that the material parts of the embryo were formed by the menstruous secretion, and that the semen of the male impressed upon them, when formed, the principle of life, by which the embryo was brought to perfection.

146. Galen believed that the embryo was produced from the male, but that it obtained nourishment from the female.

147. The illustrious Harvey, whose researches on generation occupied a considerable part of his life, seems to have been fully aware of the almost impenetrable mystery in which the process was involved; for after detailing many observations, the results of his sagacious and persevering enquiry, he explains his opinion on conception, by an allusion to the almost incomprehensible properties of the magnet; he tells us that as iron, by friction with a magnet, becomes possessed of magnetic properties, so the uterus, by the act of coition, acquires a plastic power of conceiving an embryo, in a manner similar to that by which the brain is capable of apprehending and thinking. Videtur sanè fæmina, post tactum in coitu spermaticum, eodem modo affici, nulloque sensibili corporeo agente prolifica fieri, quò ferrum a magnete tactum, hujus statim vi dotatur, aliaque ferramenta ad se allicit.—*Harv. Exercitat. de Concept.*

148. The opinion of Hamme, adopted by Leuwenhoeck, obtained great celebrity and applause, as the facts on which it rested were supposed to be demonstrated by the microscope. He asserted that in the semen of all male animals there was an infinite number of animalculæ, in each of which were contained the perfect rudiments of a future animal of the same kind; and that these required no other assistance from the female but a proper bed for their habitation, and nutriment for their expansion. This opinion was soon met by the observation of mixed generation, as in the case of a hybrid or mule, which, being procreated by two animals of different species, partakes in an equal degree of the nature and likeness of the male and female parent. This seems an unanswerable refutation of the doctrine, and it is now universally believed that Leuwenhoeck's animalculæ are nothing more than parts fitted for organisation.

149. At length the aid of chemistry was brought to bear upon the subject. The chemists presumed that the male semen was of an acid and the female of an alkaline quality, from the mixture of which an effervescence arose. From some particles which subsided, on the conclusion of the effervescence, they fancied that the embryo was formed, the fluid parts becoming the waters of the ovum.

150. Dr. Blundell, in some published 'experiments on a few controverted points respecting the physiology of generation,' says that among the various questions which have been raised, respecting the generation of animals, there is one as yet undecided; which has not, perhaps, been hitherto investigated with all the care it deserves. It may be demonstrated that, in this curious process, the male furnishes the semen, and the female the rudiments; but whether these two substances must have access to each other, in order that the young animal may be formed, is a question which still admits of dispute. Notwithstanding the labors of physiologists, we are not as yet in possession of any regular system of experiments, proving that the semen must have access to the rudiments in those forms of brute generation which most nearly resemble our own. In the present state of our knowledge the result of this position seems, at least, not improbable, as the experiments of Dr. Haighton have shewn that

evidences of generation may be produced in the ovaries, although the semen has been excluded previously to sexual intercourse by the closure of the fallopian tube.

151. On a review of the results of his experiments, Dr. Blundell thinks it not improbable that, for the completion of generation, the semen must have access to the rudiments, and yet that, notwithstanding the necessity of these approaches for its completion, the process to a certain extent may be accomplished without them. These are the two leading propositions it has been his endeavour to establish: at the same time he has further attempted to show that the corpus luteum is not a proof of genuine impregnation; that the semen, at least occasionally, penetrates as far as the ovaries; and that, however copiously this fluid may be absorbed into the vessels, it is incapable of giving rise, by any impression there, to the complete circle of the generative actions.

152. *Sterility.*—Sterility may depend upon many causes; but the chief are, we think, too early marriage, ill health, too frequent sexual intercourse and dysmenorrhœa. We have frequently observed that very young married females have not had children, and that a deranged state of the female health has prevented conception, which has taken place where the health has been restored. The effect of frequent intercourse in inducing sterility is obvious from the case of prostitutes, in whom it is said, the fallopian tubes frequently contract adhesions with the contiguous parts of the peritonæum; and the influence of an opposite state of things is deducible from the fact of the prolific results of the marriages of old men with young wives. Dysmenorrhœa, menorrhagia, and the formation and evolution of a false membrane from the internal surface of the uterus, are frequently attended by sterility. In one lady there was dysmenorrhœa, with a profuse flow of the catamenia and of coagula for ten years of marriage, and then conception took place; but at this very time the uterus itself was diseased, with morbid growths and partial suppurations formed in its substance, of which the patient died a few days after delivery. This subject is altogether a very interesting one; but it requires fresh investigation. To restore the general health—to limit the frequency of intercourse—and, in cases of dysmenorrhœa, a mercurial course, offer the greatest chances of success in the removal of this evil.

Of the Signs and Diseases of Pregnancy.

153. It is to be expected that so important an organ as the uterus, on the occurrence of any great change in its condition, should evidence such change by indications in other parts of the body. The law of sympathy is one of universal prevalence, and the uterus may fairly be considered the great centre of this influence in the female system. We have already seen that the perfect development of the uterus, or the establishment of that function which capacitates it for conception, is attended by many remarkable consequences, and in pregnancy these effects are not less astonishing: there is scarcely any part or viscus, there is scarcely any action throughout the whole system, which is not influenced in a greater or less degree by impregnation.

154. These changes have naturally excited much attention, not only from their furnishing proof that conception had occurred, but also from their originating symptoms which, if not controlled, would in many instances induce an abortive result of the generative action. Hence it is that medical writers have elaborately investigated these circumstances, and with the signs of pregnancy have generally dwelt at length on these changes, which they have denominated its diseases.

155. It is evident that the term disease, in this use of it, requires some qualification. We do not attach the same meaning to it as in affections independent of pregnancy; but, as some of the disordered actions of this state are so trivial as to be regarded merely as signs of its existence, so there are others, especially in the more advanced periods, which require judicious medical aid. We shall here adopt the common division, and shall class the affections of this state under two heads, the symptoms of early, and the symptoms and diseases of more advanced pregnancy: regarding the quickening as the point of separation between the two By this arrangement we follow out our own view of the subject, that the changes immediately consequent on conception rarely demand the appellation of disease; while those of the latter class, however naturally connected with the gravid state, do sometimes require the most decided and prompt treatment. It must, however, be remarked that, as in fever there are scarcely two cases which exactly resemble each other, so in pregnancy there is the utmost diversity; some women, if they suffer at all, complain only of the slightest inconvenience; while others regard the time of gestation as replete with indisposition and miserable sensations. In some instances there is so little sympathy or consent of parts that pregnancy seems to proceed independently of any other organ; while in others every function of the body partakes of the irritability which impregnation has induced. And, although the division we have adopted is generally correct, we do find that some women are so affected, by the least increase in the weight of the uterus, that the symptoms arising from pressure on the neighbouring parts appear in the early months. On the whole the gravid state is not necessarily one of disease; it is an altered condition, productive of less or greater inconvenience in proportion to the observance or neglect of a simple and natural course of life. If, because of conception, healthy exercise be abandoned, and the ordinary occupations of life be laid aside, while the same quantity of nutritive and perhaps stimulant food continues to be taken, we have here a cause of disease which, independently of pregnancy, would induce the most injurious effects. And, while we are aware of the necessity which sometimes exists in certain periods of this state for quietude and repose, we cannot forbear the expression of our opinion, that a moderate degree of activity will conduce not only to less inconvenience during gestation itself, but to an easier labor. The example of women of the lower classes, who follow laborious occupations in the open air, without scarcely any regard to pregnancy, is decidedly in favor of this conclusion. Nor can we divest ourselves of the

belief, that the favorable or unfavorable circumstances of the mother, during pregnancy, more especially as it regards her active or sedentary and luxurious mode of life, do very often materially influence the health and vigor of her offspring? We do not assert this as an established fact, but we have been led to a conclusion of the kind from observing, in a few instances, where we knew the mother to have been remarkably inactive and indolent during her pregnancy, that the children were torpid and sluggish in the performance of all their functions; more especially in the healthy evacuations of the contents of the intestines. In two instances, occurring in the same family, we thought we could perceive great tendency to hydrocephalus from this cause.

156. *Signs of the early months.*—The suppression of the menses is generally the first circumstance which leads women to suspect pregnancy. It is undoubtedly true that amenorrhœa may, and frequently does, arise from other causes; but, as a single sign, we think it of great value. Dr. Denman affirms that he has never known a pregnant woman menstruate; and in this opinion we agree, although instances have occurred to us where there have been, in the early months, several returns of a sanguineous discharge, thrown off in clots and coagulating, similar to the menses in color, and arising, perhaps, from the upper part of the vagina and about the cervix uteri.

157. These discharges have not observed any regular intervals; they were not ushered in by any symptoms characteristic of approaching menstruation; nor did they continue beyond the third or fourth month. The discharges of a later period may, we conceive, be explained on other grounds.

158. We have lately been called upon for an opinion in some cases of doubtful pregnancy; and though there was in all of them abdominal and mammary enlargement, and in others more or less of the various symptoms of this state, in none was there suppression of the menses. For ourselves we should feel more confident of the existence of pregnancy from an entire suppression of the menses, all other signs, with the exception of abdominal increase, being absent, than we should from the united assemblage of all the other indications, if the menstrual secretion continued with its accustomed regularity.

159. Cardialgia, nausea, and vomiting, are almost constantly attendant on conception; there are instances, and we have known several, where there is scarcely a sensation of sickness throughout the whole period; these are, however, very rare, as it much more constantly happens that during the whole of the early months, immediately on getting out of bed, there is a vomiting of a glairy, and sometimes of a bilious, fluid. Puzos considered vomiting as very salutary; and Denman says, if it should not be very violent, and if it occur only in the early part of the day, it is generally found to be serviceable by exerting a more vigorous action of the uterus, and by bringing the stomach into a better state; for the vomiting of pregnant women is not always a mere effort of straining, or a discharge of the food and common humors of the stomach. The matter evacuated sometimes shows a very disturbed state of the stomach, or a morbid secretion of such a kind as to be offensive to the stomach itself; and besides correcting or evacuating the offending humors, it is necessary that we use our endeavours to change or to appease the present action before the indication to vomit be suppressed. We know not how far vomiting may be beneficial in this state; it certainly does occasionally relieve the stomach from an accumulation of disordered secretion, and thus far is of service; if, however, it should continue to the later months, when the abdomen is large, and its parietes distended, we shall hear very frequent complaints of the straining and spasm to which it gives rise. At this time, as well as earlier, it will be right to attempt its mitigation by the various remedies usually employed for this purpose. The application of leeches to the pit of the stomach, of a small blister, or of an opiate plaster, with an additional quantity of this substance in its composition, or of brandy and opium in a liquid form, all being externally employed, will frequently produce great relief. One grain, or a half, of solid opium, we have frequently given with most decided advantage; and in the latter periods, when the head sympathises in the disturbance, it may be necessary to take away blood from the arm or from the back of the neck; mild aperients and laxatives must be exhibited. It is deserving of notice that the vomiting generally comes on when the patient changes from the lying to the erect position; and it is frequently useful to maintain for some little time the recumbent posture. We lately attended a lady who was much distressed by heart-burn; and, after going through the whole round of remedies, she commenced taking prepared chalk, and through several pregnancies consumed an ounce of it every two or three days. It had this additional advantage, that it not only relieved the heart-burn, but preserved the bowels in an invariably aperient and comfortable state. It is manifest that these affections are only important as signs of pregnancy when they concur with the whole series of indications appertaining to this state; for no one would presume a woman to be pregnant, in the absence of other proofs, merely because she was sick and vomited. Loss of appetite accompanies pregnancy, but it is a sign on which evidently no dependence can be placed. Pregnancy is often accompanied by a continual tendency to febrile excitement, the pulse is increased, the palms of the hands and the cheeks are not unfrequently flushed, and emaciation and irritability of manner are the result. If any inflammatory disease should occur in pregnancy, and even independently of such circumstance, the blood, when drawn, will have a sizy appearance: its constituent principles being slightly altered.

160. Great stress has been laid on the enlargement of the mammæ, and, if it be accompanied with tenderness, flying pains, and a secretion of milk, it is a very satisfactory sign. It must, indeed, be recollected, that the increased enlargement of the breasts may arise from adeps as well as pregnancy.

161. If it be merely an accretion of cellular substance, or fat, it will have a soft cushiony feel; if it be originating from pregnancy it will

have a glandular, rather knotted, and uneven character.

162. The areola has been regarded almost as an infallible sign in first pregnancies. We have known three instances where it was increased in breadth, decidedly darkened in color, and where there was slight secretion from its surface, without the existence of pregnancy. If it concur with the other indications, it is a valuable auxiliary corroboration.

163. Having now described those changes which almost invariably attend early pregnancy, we shall briefly notice some anomalous and occasional affections, arising from peculiarity of constitution, such peculiarity being excited into activity by gestation.

164. Frightful dreams are, in some individuals, a very good diagnostic sign; and Dr. Haighton used to relate the case of a lady, under Dr. Lowder's care, who was compelled to hire a nurse to awake her when she was very much discomposed in countenance. We occasionally attend a lady, who invariably knows herself to be pregnant, by pain in the teeth; and many women unerringly arrive at the same conclusion, from the existence of painful sensations in unusual parts, as the toes, fingers, ears, &c.

165. We may remark here that the anomalous signs are not very valuable in first cases, and for this reason, that, not having been previously pregnant, a patient cannot tell whence they arise, or with what state of system they are connected. We have before observed that pregnancy is not a morbid, but an altered state, and plethora or increase of the circulating fluid may be enumerated amongst the causes giving rise to some of the diseases of pregnancy. There is one affection, probably arising from this cause, which is very distressing, although happily not very common, we mean the prurigo pudendorum muliebrium. We are aware that women are subject to this disease independently of impregnation; and we mention this fact the more willingly, from having seen two cases, where conception seemed to have been prevented by its continuance; at all events, it occurred immediately on its cure.

166. The most interesting case occurred in a lady of twenty-six, who had been married five years, and had menstruated regularly during that time. For the last three years she had suffered so acutely from prurigo as to render connubial intercourse impossible. She had followed almost every professional opinion, and every remedy seemed to have been tried unsuccessfully. We put her on a gentle mercurial course, there not being the slightest reason for suspecting any venereal taint; and the affection of the gums was kept up in a slight degree for two months. At the end of this period she was so much improved as to disregard the prurigo, and in another month she became pregnant. The child when born was healthy and strong.

167. Irritability of a nervous and hysterical kind is frequently appearing in pregnancy; it will not be relieved by the abstraction of blood; mild aperients may be given; but when it occurs, as is generally the case, with women of spare and delicate habits, calumba bark and valerian, or any stomachic, given in the form of infusion, will do good. Women, when but little advanced in pregnancy, often complain of inability to walk, accompanied by pain in making water, and a discharge from the vagina, which last, as it may be satisfactorily attributed to pregnancy, ought not hastily to be considered venereal. In cases of suppression of urine Dr. Haighton used to recommend that females should be instructed to relieve themselves, by passing up the finger to the os uteri, raising it up, and thus taking off the mechanical pressure from the womb; and if, in addition to this, they hold their breath, and force down, the urine will often be discharged.

168. *Retroversion of the uterus* used to be regarded with extreme apprehension, and, were we to judge from what has been written respecting it, we should think it an occurrence of the most dangerous kind. The fears which were formerly indulged are considerably modified; it being now well known, that in many instances the timely and continued introduction of the catheter will suffice for its removal; and even where this is not the case, if other circumstances are favorable, it may be allowed to continue for some time without fear of injury. We do not urge these remarks as an apology for ignorance and inattention, but rather to allay any undue excitement either in the practitioner or the patient, and to prevent any unnecessary and meddlesome interference, which might, by producing abortion, originate a mischief worse than the original affection. Retroversion consists in an alteration of the position of the womb; and, for the first accurate description of the change which the uterus suffers, we are in this country indebted to Dr. Hunter, in 1759, Gregoire and Levret having previously written upon it.

169. If the pelvis be of the usual size, it may occur in the third or fourth month, and, if rather more capacious than common, as late as the fifth. The attention of the patient is first excited by difficulty in passing the urine; and by tenesmic sensations in emptying the rectum. If the retroversion be complete we shall, on examination, discover a tumor formed by the fundus uteri, between the vagina and the rectum; and the os uteri, if felt at all, will be found turned upwards and forwards towards the pubes. If an examination be made, per anum, the fundus uteri will be ascertained forcing the rectum into the hollow of the sacrum; and, if the finger of the other hand be in the vagina at the same time, it is not difficult to determine that the uterine tumor is confined between the rectum and the vagina.

170. Retention of urine is the most common cause of retroversion (Dr. Denman's Introduction to Midwifery, p. 78); and women who live in an humble situation of life, or in an unrefined state of society, are scarcely ever liable to this complaint, because they are free from the restraint of company, and can evacuate the contents of the bladder whenever it is necessary. Those in the highest ranks, not being ashamed to withdraw from company, are nearly in the same situation.

171. But those, who, in a middle state of life, with decent yet not over refined manners, have

not cast off the bashfulness of the former, nor acquired the freedom of the latter, are most subject to the retroversion of the uterus. The great danger in this case arises from not ascertaining the precise character of the disease; although even here, if the bladder be emptied, alarming consequences are not likely to ensue. Our first object then is to evacuate the urine, and the catheter may be slightly curved, the concavity being directed to the sacrum, or we may use a flexible male catheter, although in general the common instrument succeeds. The catheter must be very slowly and delicately introduced, and should not be pushed further into the bladder than is necessary to relieve the distension. We may, perhaps facilitate its passage, where there is difficulty, by introducing the finger into the vagina, and depressing the os uteri, at the same time relieving the bladder from the vaginal tumor. Pressure on the abdomen will enable us more completely to empty the bladder. As soon as we have completed this operation, a clyster or some aperient medicine should be exhibited.

172. Instances are recorded where the retroversion has been immediately removed on the evacuation of the contents of the bladder; but it may continue, and Denman seems to think that, if the symptoms are not urgent, the uterus may remain in a retroverted state for many days or weeks, without any other detriment than what may be occasioned by the temporary interruption of the discharges by stool or urine: and, contrary to all expectation, it has been proved that the uterus, when retroverted, will often be gradually and sometimes suddenly restored to its position, without any assistance, provided the cause be removed by the occasional use of the catheter. It appears that the enlargement of the uterus, from the increase of the ovum, is so far from obstructing the ascent of the fundus that it contributes to promote the effect; the distension of the cervix becoming a balance to counteract the depression of the fundus; for no cases of the retroverted uterus admit of reposition with such difficulty as in women who were not pregnant, in whom the uterus underwent not any or no material change.

173. In the practice to which these statements would give rise we accord to a great extent, but if, in the course of a short time, a reposition of the uterus did not spontaneously occur, we should feel disposed, by manual assistance, to attempt the replacement. Having put the patient in such a position that the hips shall be more elevated than the shoulders, and the thighs brought to right angles with the body, we may pass one or two fingers into the rectum; and then, by the aid of a piece of sponge, fastened to the end of a small bit of cane, according to Dr. Haighton's suggestion, gently pushed up the gut, until it comes in contact with the promontory of the sacrum, we may act on the retroverted womb; and now two fingers may be advantageously introduced into the vagina, so as to depress the cervix uteri, thus influencing the womb from two points. If we fail, after a judicious repetition of these measures, Dr. Hunter advises that the ovum should be tapped, so that, by letting off the water, its bulk should be diminished Even if we succeed the bladder will require sedulous attention; and, at least till quickening is fully established, we must prevent any extensive accumulation of urine in this viscus: of course, when the uterus has fairly emerged from the pelvis into the abdominal cavity, it cannot again be retroverted.

Of Quickening.

174. The quickening of the child, so termed because, at this period, it was erroneously supposed to be endowed with the principle of life, is an important event. The earlier affections of pregnancy, or those which may be supposed more especially to depend on the irritability connected with this state, are now yielding to a new class of affections, which result in a great measure from the increased weight of the womb, and from its consequent pressure on surrounding parts. We must allude, before we proceed further, to the erroneous opinion, so long entertained, and on which the English law is founded, that when the child quickens it first acquires vitality. From the moment of impregnation the fœtus is in possession of this principle; and it is only at this time, from circumstances we are about to explain, that it affords increased manifestations of this power. It is to be expected, when the uterus is confined within the cavity of the pelvis, and when the proportion of the liquor amnii is large compared with the size of the child, that its movements should be indistinct; but when the relative quantity of water is smaller, when the womb has fully emerged from the pelvis cavity, into a situation where it is less restrained, and where the sensibility is perhaps greater, the motion is stronger and more decidedly felt. It is possible for women to be deceived by the intestinal movements of wind, fancying that they are the motions of the child.

175. This deception most frequently occurs where there is a disposition to favor the idea of pregnancy. If this feeling did not exist it would be easy to convince such patients that genuine uterine sensations, produced by a child in the cavity of the womb, can only be felt in certain parts of the abdomen. We are now in attendance on a lady who, from irregularity in the menstrual discharge, supposed herself in a state of pregnancy; she is twenty-six years old, and has been married five years without having been once pregnant. Several of the early signs of pregnancy, as slight nausea, darkening of the ariola, and capricious appetite have existed. The breasts are much enlarged, and the abdominal intumescence is considerable. We have always entertained doubts as to this lady's state; for during the eight months of supposed gestation she has very sparingly menstruated six or seven times. On examining the abdomen we perceived the fundus uteri behind the ossa pubis, and we felt convinced, on further pressure by the hand, that the abdominal enlargement was principally attributable to adeps and air. On examination, per vaginam, the cervix uteri was not at all developed; it was of its original length, and we were able distinctly to ascertain that the uterus was not at all increased in size. We think

these are the cases of supposed pregnancy most commonly occurring; a lady is desirous of having a family, never having perhaps been a mother, or having advanced to that age when it is improbable she shall again bear children. From some accidental circumstance the menses become irregular, or they are suppressed for a few weeks beyond the usual period. Expectations are cherished; rest is enjoined; and capricious appetite, in conjunction with some other of the early signs, leads the patient to believe that she is most probably pregnant. When menstruation again occurs it is thought rather unnatural; but as every effort is employed to diminish its quantity, and to shorten the time of its flow, it may not continue more than a day and a half, or two days. Indolence and indulgence succeed to activity; the same quantity of nutritious food continues to be taken; the bowels become torpid from want of exercise, and from the accumulation of the ingesta. If we add to these circumstances the secretion of air in the intestinal canal, the deposition of adipose matter in the abdominal integuments, and the fatty enlargement of the mammæ, we have no difficulty in comprehending how patients may deceive, not only themselves, but, by strong statements of their symptoms, even their medical attendants.

176. We could enumerate several such cases as these, and one in particular, where the abdomen was never exceeded in size, in the ninth month of pregnancy, except perhaps in the case of twins; and where there was every concurrent indication, excepting the suppression of the menstrual secretion. It is needless to add, that even here there was no pregnancy. We wish to observe that the practitioner ought never absolutely to commit himself, as to the existence of pregnancy, without an examination of the uterus itself; and, as much as possible to simplify and illustrate this important and practical part of our subject, we shall recapitulate a few particulars. The fundus uteri, when it ascends from the cavity of the pelvis, is situated forwards, and its mouth and cervix posteriorly; it is manifest, therefore, that the intestines cannot lie before it (an important circumstance in external enquiry); but they must be situated posteriorly and at its sides.

177. The fundus again, previously to its ascent, and in proportion to its increasing development, will afford a large surface for the pressure of the superincumbent intestines; and the mouth and cervix uteri, will necessarily be forced lower down in the vagina. The mouth of the uterus is always sufficiently open, in the unimpregnated state, to admit easily the tip of the finger. Soon after conception it is closed, and is only to be penetrated, if gentle efforts are employed first within its edge. As pregnancy advances it becomes gradually softer, although it is not till the fifth month that the cervix is decidedly developing itself. In the seventh month this process is so far advanced that we may, by a well conducted examination, feel the head of the child; in the eighth month the neck is completely destroyed for the purpose of enlarging the uterine cavity; and it is situated as high as the brim of the pelvis.

178. These facts should always be impressed on the mind, whenever we make an examination; and if we conduct it slowly, remembering that the indications furnished by disease resemble to some extent those of the gravid state, we shall not be liable to error. If we examine in the second month, which is seldom required, and still more rarely necessary, we shall perceive the gravitation of the uterus downwards, and the cervix will be closed. When elevated by the finger it will to an experienced examiner feel heavier, and rather more resisting than in the unimpregnated state. We should not, however, express a decided opinion from the indications of this early period. In the third and fourth months, we may arrive at greater certainty, from the increased size and weight of the womb. During the fifth month an examination may be conducted with confidence, the uterus having risen above the brim, and by pressing its fundus we may impart to the fingers in the vagina a distinct sensation of resistance and rolling. Under these circumstances we can at any rate pronounce the womb to be enlarged; and, if we hesitate as to the precise nature of its contents, we have at least obtained some positive information. After this period the alterations of the cervix, the increasing development of the uterus, and the movements of the child, will generally conduct us to a certain and well grounded opinion. If there be any doubt, after examining by the vagina alone, we advise the practitioner to introduce one or two fingers into the rectum, thus placing the uterus between the action of both hands, in which case he can scarcely fail to ascertain with precision the extent of the enlargement. He may also introduce a catheter into the bladder, and, by gently moving about its rounded extremity in the cavity of this viscus, he may press the uterus backward against his fingers in the rectum, and thus acquire additional information as to its size and condition.

179. We shall now treat of the class of complaints incident to the *advanced stages* of utero-gestation, of which it is scarcely necessary to observe that they are more painful and dangerous than those we have already enumerated. For, while the death and premature expulsion of the fœtus is the worst result of the one, the safety of the mother, as well as the destruction of the child may be involved in the other.

180. Nausea and vomiting may still continue to render it necessary to maintain an almost entirely empty state of stomach, nourishment being acquired by clysters of beef-tea and jelly. The occasional exhibition of solid opium will prove highly advantageous, notwithstanding which the vomiting may go on to harass and debilitate the patient, and may reduce her to a state of extreme danger. In these circumstances it is very justifiable to induce premature labor; and we regret that an attempt of the kind was not made in the subjoined case. Dr. Marshall Hall mentioned to us the case of a lady, in whom vomiting continued in spite of every remedy which a most experienced practitioner could suggest, and induced a fatal termination in the seventh month.

181. Jaundice sometimes occurs in the latter stage of utero-gestation, more as the consequence

of the state than from any schirrosity of the liver or disease of the biliary ducts. The treatment is generally confined to palliatives, although there is perhaps no sufficient reason why pregnant women should not bear the operation of the proper remedies for its cure. For ourselves we should especially recommend an early regard to affections of the liver during pregnancy, if they be conjoined with inflammation. A lady, the wife of a very able practitioner in the country, was attacked with symptoms of jaundice in the latter months; they were not disregarded, but inflammation of the liver succeeded, and in spite of the most vigorous treatment it terminated fatally in a few days.

182. *Costiveness* is often a very troublesome attendant of the later periods of gestation, arising from the pressure of the enlarged uterus on the rectum. We do not advocate the continued exhibition of purgatives, much less those of an aloetic or drastic kind; still, as torpor of the bowels is naturally incident to pregnancy, we are always desirous of preventing any such accumulation of feculent matter as may give rise to what has been vulgarly denominated the 'ball stool.' Not to dwell on the distressing sensations produced by excessive and almost continual constipation previously to labor, we have known during the act of parturition itself very serious delay arising from this cause, and more than once we have been compelled to empty the rectum before the head could be propelled into the world. Denman says 'that he was at one time very assiduous in preventing costiveness; but that afterwards he became much less so, observing that all women who went on properly, especially in the early part of pregnancy, were liable to this state of the bowels, which may have some relation to the strong action of the uterus at that time. Costiveness may, therefore, be considered as a state of the bowels corresponding with that of the uterus; and we never can believe that to be injurious which occurs so frequently as to be esteemed a common consequence.' We may further observe, in corroboration of this statement of Dr. Denman's, that not only is abortion most frequent in those patients who are habitually prone to too relaxed a state of the bowels, but that it is frequently produced by the relaxation which succeeds the exhibition of aperients or purgatives.

183. Women during pregnancy must resort to opening medicine, and we should enjoin the use of that which is most simple and mild. A teaspoonful of castor oil taken three or four times a week on going to bed, aided on the following morning by the injection of a pint of warm water into the rectum, will frequently preserve a comfortable aperient state of the bowels throughout the whole period of gestation. Magnesia in small doses, perseveringly taken, is sometimes productive of equal benefit; although from its chemical properties it is often uncertain, and sometimes violent in its operations.

184. *Hæmorrhoids* are occasionally requiring treatment, and gentle aperients or some of the preparations of sulphur are productive of good. If they are very numerous and much tumefied, leeches may be employed; but pressure on each individual pile, till its cavity be emptied of the blood it contains, will impart much relief.

185. *Affections of the brain*, of the slighter kind, are not very unusual in utero-gestation, and from whatever cause they may arise, whether from a fulness in the vessels of the brain, induced by compression of the vessels of the lower parts of the body, or from an unusual degree of the irritation which to a greater or less extent almost invariably characterises pregnancy, they demand the most careful, and, in some instances, the most prompt treatment. We cannot divest ourselves of anxiety, lest vertigo and head-ache in the latter months should precede convulsions, immediately before or during labor: nor can we expect a complete removal of their effects, if they have been severe, till after parturition. We were a few months since called to a patient in the fifth month, who had suddenly lost the power of distinct articulation, and the perfect command of the left side of the body. The abstraction of sixteen ounces of blood slightly restored her speech, but it was not until blisters, leeches, cupping, and purgatives had been employed, that she spoke at all distinctly. This lady was confined prematurely, without any disposition to convulsion, and the child was born alive. Two months elapsed after delivery before she fully regained her usual articulation.

186. *Syphilis* is occasionally complicated with pregnancy, and there is no doubt of the perfect safety of submitting a patient, under such circumstances, to a judicious and mild mercurial course. By this treatment the mother will be cured, but we are not always so successful with the child; for, although it may be born free from any appearance of disease, yet in the course of a few weeks symptoms of syphilis are not unfrequently occurring. In a lady we lately treated for this disease, and who became pregnant during its continuance, the child was born with copper-colored spots all over its body, although the mother had been perfectly cured for at least five months previously to delivery. This infant was subsequently affected by thrush, and ulcers soon appeared on the arms and labia pudendi. At this time we were not in attendance, but we were informed by the gentleman who had charge of the case that these sores resisted all the simple methods of treatment, and did not heal, till a mercurial plan was pursued. Mr. Hey, whose reputation has scarcely been excelled by any surgeon in this country, states 'that syphilis in its secondary form may be communicated by the mother to the fœtus in utero.' 'That the fœtus may be contaminated when the mother has never been previously affected with lues venerea in the organs of generation, and when no apparent disease existed in the father at the time of impregnation.' 'That the mother remaining in health shall produce several children each of which shall in succession become affected with syphilis a few weeks after its birth and that the disease shall assume a milder form, in each child comparatively, until it be finally worn out.' Mr. Hey confirms these separate statements by a reference to clearly defined cases, in the treatment of which he completely succeeded by the mercurial plan

187. When dropsy or a true ascites is connected with pregnancy, the treatment will require very serious consideration. If the degree of the abdominal distension is not incompatible with delivery, we shall remain satisfied to palliate the symptoms, and as much as possible to restrain the increase of the fluid. This procedure is of course to be pursued independently of any consequences occurring after delivery, these remaining to be treated according to the circumstances which may then arise. If, however, the distension occasions great pain, and endangers the life of the woman, we cannot then wait for natural delivery, we must either bring on premature labor, or the operation of tapping must be performed. Dr. Denman's views on this subject display a timidity not in accordance with the general tenor of his opinions: he says, 'if any active remedies are used for the cure of the dropsy, the child will of necessity be often destroyed, and an abortion or premature labor occasioned; and, when the operation of paracentesis has been performed, it has been known to prove fatal to mother and child, always reflecting great discredit, both upon the operator and the profession.'

188. It therefore seems necessary to establish this general rule, that no woman at a time of life, or under any circumstances which in the most distant manner subject her to a suspicion of pregnancy, should ever be tapped or otherwise treated for dropsy, till by examination per vaginam, or by waiting a due time, we are convinced she is not pregnant, even though she may have before undergone the operation.

189. Burns says, 'when dropsy is arising from the ordinary causes, or from disease of the liver, medicine has seldom much effect in palliating or removing the disease, and the woman usually dies within a week or two after delivery, whether the labor has been premature or delayed till the full time.' Burns is of opinion that if the distension be very great, especially at an early stage, a great part of the fluid may be safely drawn off after quickening, if during the operation, and afterwards, the abdomen be carefully and uniformly supported by a bandage. He thinks the operation is more likely to be succeeded by labor, if performed in the last month, than earlier. A case of ascites, connected with utero-gestation, most ably treated by Mr. Langstaff, is recorded in the twelfth volume of the Medico Chirurgical Transactions. In this case Drs. Farre and Davis, having seriously considered the important nature of the disease, were of opinion that the bringing on of premature labor was preferable to drawing off the water. The unwieldly state of the abdomen, the inability to recline in the horizontal posture, and the immense size of the legs and thighs, rendered the patient indescribably miserable. The liquor amnii, in accordance with these opinions, was discharged; but on the following day as there were no signs of labor commencing, and as dissolution appeared rapidly approaching, Mr. Langstaff cut down to the peritonæum, about two inches below the umbilicus, carefully perforating that membrane, with a moderate sized instrument such as is commonly employed in performing the operation paracentesis abdominis. The fluid, which flowed very freely, was transparent, and, when about ten pints of it had passed off, a moderately large, smooth, and soft elastic gum catheter was introduced through the opening, which, passing downwards for several inches between the anterior part of the peritonæum and uterus, drew off the remainder of the fluid, amounting in the whole to twenty-five pints. Three days after this operation labor occurred, attended by no remarkable circumstance, excepting the detention of the placenta. In the interval between the tapping and the delivery it was found necessary to abstract fifty ounces of blood twenty ounces being taken at one time, and thirty afterwards. In nineteen days after the labor this lady was considered out of danger, and without any dread of re-accumulation of fluid in the peritonæal sac. In conclusion Mr. Langstaff remarks that, from the favorable result of this and Scarpa's case (page 249 of the Quarterly Journal of Foreign Medicine and Surgery), he should be induced to recommend tapping before the hydropic symptoms became so distressing; and from what he has seen of dropsy, occasioned by plethora, or an inflammatory state of the arteries, he should expect that the further effusion of fluid into the peritonæal sac, during pregnancy, might, if detected before the accumulation was considerable, be prevented by blood-letting, and ultimately the absorbents might be induced by proper treatment to carry off the fluid. But this fortunate termination could only be expected where effusion was merely the result of simple inflammatory action, unconnected with visceral disease.

PART III.

LABOR IN ALL ITS VARIETIES.

190. Having now completed the preliminary divisions of our subject, and trusting that although concisely they have been clearly and comprehensively treated, we shall at once proceed to the practical part of the science, by which the truth and value of all its principles must ultimately be tried. If hitherto we have endeavoured to select, from the general store of obstetric knowledge, what appeared necessary to be fully known; so in this part, by far the most important and responsible in midwifery, we shall aim to present the rules of the art in as simple and efficient a form as possible. Here we discover the improvement of midwifery, and we shall feel surprised, if we retrace its progress for the last 150 years, at the perfection it has attained. We think there are few if any cases, excepting anomalous ones, which a practitioner may not be prepared to encounter; and if, with the information to be thus attained, he combines judicious promptitude, tact, and delicacy, there is no difficulty in believing that he may practise midwifery with comfort and success. Let it however be remembered, that if, in the case of an important artery being wounded, it may be necessary for the surgeon instantly to exercise his anatomical knowledge and surgical skill; so in sudden hæmorrhage, occurring in parturition, if the man-

ner of procedure have not been previously arranged the patient may die in the few minutes required for deliberation. The term of utero-gestation in the human species has been much controverted; a variety of causes has contributed to this difference of opinion; females on such subjects do not give correct and precise information; practitioners commence their calculations at different periods, some immediately before, others directly after, the last appearance of catamenia, while it is by far the most common to commence the reckoning from a fortnight subsequent to the last menstruation. We believe that few cases of pregnancy will be found to exceed forty clear weeks from the time of conception; although we are not disposed to acquiesce in the opinion recently delivered in the house of lords, that the term of pregnancy cannot exceed 280 days, or ten lunar months. We find in other points relative to conception, gestation, and parturition, an almost infinite variety; nor can we yet discover any facts irrefragably proving that the general term of human pregnancy cannot be exceeded. We are fully aware that this question will not admit of arguments from analogy, or these would favor the opinion to which we incline. We trust that future and more correct observation will determine this litigated point, not merely for the purpose of demonstrating who are right, but that in cases where it is necessary to induce premature labor, we may do it with the utmost probability of preserving the life of the child. A few years since we attended a lady who gave us the following particulars, and on their accuracy we can rely. She ceased to be regular on the 25th of January; a few days afterwards her husband set out on a journey, and remained absent about six weeks; there was no return of the catamenial discharge, and she was not confined till November the 27th of the same year, a period probably of 304, but at all events of 300 days, from the last menstruation. This lady was unusually large, and her child much finer than any she had previously borne. Hippocrates extends the term of utero-gestation to ten months; and the Roman law, founded probably on the opinion of Hippocrates, allows ten months to ensue between the death of the husband and the legitimate birth of the offspring. France, we believe, has adopted this term; and Haller has furnished examples of pregnancy extending to eleven and even twelve months. Our own law has not prescribed any imperative rule on this subject, preferring rather to be guided in its decisions by facts, which, in the opinion of those most capable of estimating their value, may influence individual cases.

191. Dr. Merriman, the author of a valuable work on difficult parturition, has bestowed considerable attention on this subject. He informs us, 'that he is very exact in ascertaining the last day on which any appearance of catamenia was distinguishable, and has reckoned forty weeks from this day, assuming that the 280th was to be considered as the legitimate day of parturition. Of the births of 114 mature children, calculated from, but not including the day on which the catamenia were last distinguishable,

3 occurred	in the	37th week.
13	. .	38th.
14	. .	39th.
33	. .	40th.
22	. .	41st.
15	. .	42nd.
10	. .	43rd.
4	. .	44th.'

The position of the child in utero has been variously described; it used formerly to be thought that it sat or rested with the breech on the brim of the pelvis, the foreparts of the child being turned towards the abdomen of the mother. Before the different stages of labor were correctly understood and described it was believed that at the time of parturition, principally by its own weight, the head descended into the cavity of the pelvis, in such a direction that its vertex was turned towards the ossa pubis, and its face into the hollow of the sacrum.

192. Harvey has investigated the position of the fœtus in utero with great care, and we shall present his account to our readers, premising that the arrangement of its parts is such as to occupy the least possible space, affording the utmost facility to its own movements, and as little inconvenience as possible to its parent. We may also remark that it is highly probable its situation remains the same during the whole term of gestation, so that, if the head lie over the centre of the pelvis in the commencement, it will generally be so situated at the termination of pregnancy, unless there have been any violent actions or movements on the part of the mother.

193. The general position is as follows:—the knees are drawn up to the belly, the legs are reflected backwards, the feet crossed, and lying close to the breech; the elbows are in contact with its sides, and the hands turned up to its head, one of which is often placed upon the cheek or ear. The spine is incurvated, and, the neck being bowed, the chin rests upon its knees. There is that inflexion of the body into which we spontaneously fall, when we seek repose; and, as it is our position before we are born, it is that also to which we have an inclination in the decrepitude of old age. Adductis ad abdomen genibus, flexis retrorsum cruribus, pedibus decussatis, manibusque sursum ad caput sublatis, quarum alteram, circa tempora vel auriculas, alteram ad genam detinet, spina in orbem flectitur, caput ad genua incurvato collo propendet; tali membrorum situ, qualem in somno quietem quærimus.—Harv. Exercitat de partu. The bulk of the body of the child is not placed against the spine, but on one side, most commonly on the right, and the limbs are turned towards the left, so that the abdomen of a woman with child is in general evidently distended more on one side than the other. No suspicion need in consequence be entertained that the presentation at the time of birth will be unnatural.

194. Before we commence the history of labors, in order to simplify and facilitate the comprehension of them, they may be divided into classes and orders, bringing together those which agree in some essential particulars, and

which require nearly the same treatment. By this method we shall be able to convey the practical precepts of the art with perspicuity and force. The term labor is not solely applicable to human parturition, as it may express any act performed with difficulty and pain; we cannot, however, controvert the peculiar propriety of its employment to characterise the whole of this momentous process, the circumstances of which it is well suited to describe.

195. We shall divide labors into three classes:

I. Natural.

II. Difficult.

III. Complex, or anomalous.

Class I. *Natural labor* may be defined that which is occurring at the full time, the head of the child presenting, and the process being completed within twenty-four, or twelve, or frequently within six hours, without artificial aid, or the occurrence of any morbid affection. This comprises three orders.

Order 1. Quick labor, in which the process is easily completed within the prescribed time.

Order 2. Lingering labor, the head of the child still presenting, but continuing beyond twenty-four hours, instrumental aid not being required.

Order 3. Twin labor.

Class II. *Difficult labors*, or those in which the child may or may not present the head, and where the natural powers are generally insufficient to accomplish the delivery. This comprises three orders.

Order 1. Presentations of the breech, of the superior or inferior extremities, or any combinations of these presentations, and which require manual aid.

Order 2. Labors which cannot be completed without the aid of extracting instruments, of which some are designed to save the lives both of the mother and the child; while others are intended to preserve the life of the mother, at the expense of the life of the child.

Order 3. Impracticable labor, or that in which the child, even when as much as possible reduced in size, cannot pass through the pelvis, and where the Cæsarean operation becomes necessary.

Class III. *Labors of a complex or anomalous character*, comprising three orders.

Order 1. Labor complicated with uterine hæmorrhage, including those labors where the placenta fully or only partially presents.

Order 2. Labor complicated with convulsions and syncope.

Order 3. Labor complicated with rupture of the uterus, suppression of urine, or rupture of the bladder.

196. It is very important to obtain clear and precise ideas of the progress and circumstances of natural labor; for if we have a standard pelvis and a standard head, of which all other pelves and crania may be considered only as varieties; so natural labor may form a standard, to which all others, in a greater or less degree, must approximate, their safety or danger being correctly estimated by their likeness or dissimilarity to natural parturition.

197. Thus, if any of the marks in the definition of natural labor be wanting, it must come under some other class. If, for instance, the head is not the presenting part, it must be placed in the class of difficult labors; and, if manual aid be required, it will form part of the first order of this class. Again, if the head should present, and convulsions should occur, it will not be a natural labor, but must be considered as belonging to the class of complex parturition. A natural labor, says Denman, was the last thing well understood in the practice of midwifery; because scientific men, not being formerly employed in the management of common labors, had no opportunity of making observations upon them. Practitioners were then engaged in qualifying themselves for the manual exercise of their art, whenever they might be called on to give assistance; and not in making nice distinctions, or investigating the particular cases in which only it might be necessary to exercise it.

198. Dr. Smellie supposes that, out of 1000 women in labor, eight shall be found to require instruments, or to have the child turned in order to avoid them; two children shall present the superior extremities; five the breech; two or three the face; one or two the ear; and ten shall present with the forehead turned to the acetabulum.

199. Dr. Bland says that, out of 1897 women, 1792 had natural labor. Sixty-three, or one out of thirty, had unnatural labor; in eighteen of these the child presented the feet; in thirty-six the breech; in eight the arm; and in one the funis. Seventeen, or one out of 111, had laborious labor; in eight of these the head of the child required to be lessened; in four the forceps was employed; and in the other five the face was directed toward the pubes. Nine, or one in 210, had uterine hæmorrhage before or during labor. It is evident that this register cannot form a ground for general calculation; and we perceive that the number of crotchet cases exceeds those requiring the forceps, which is not observed in the usual cases of practice.

200. We cannot form any correct opinion from the practice of individuals, as some may, from peculiar circumstances, encounter more of difficult midwifery than is fairly proportioned to the number of their patients. Thus Dr. Hagen of Berlin says that, out of 350 patients, he employed the forceps ninety-three times, and the crotchet in twenty-eight cases; twenty of his patients died. Dr. Dewees, of Philadelphia, says that in more than 3000 cases he has not met with one requiring the use of the crotchet.

201. *On the changes immediately previous to parturition.*—At the expiration of forty weeks changes occur, which intimate pretty clearly that some important process is about to be commenced, and these changes have been denominated the predisposing signs of labor. There is at this period a partial subsidence of the abdominal enlargement; and many women are able correctly to foretell, from this circumstance alone, the early occurrence of labor. Whenever the fundus of the uterus is thus descending, it indicates a favorable disposition to parturient action: for, it is well known, if, after the commencement of labor, the patient complains that the child is

very high, it is unfavorable, proving that the fundus is either inactive, or disposed to act irregularly.

202. The follicular apparatus about the neck of the womb is now pouring out a glairy and viscid secretion; which, when it immediately precedes labor, and from the rupture of some small vessels, is of a sanguineous color, we denominate show.

203. Some women, from their manner of walking at this period, and from the statement of their feelings about the pelvis, would induce the belief that there was some relaxation of ligaments, and that the popular expression of falling in pieces is not altogether unjustifiable. These changes are often accompanied by irritation of the bladder, and by griping tenesmic sensations in the intestines and rectum. These are the principal circumstances inducing the belief that the expulsatory action of the uterus is about to commence; and, in the language of old Avicenna, that the 'appointed time having arrived, labor comes on by the command of God.'

204. *Delivery*.—It is scarcely necessary to remark that in the term delivery we include the complete expulsion of the fœtus and the secundines; but as there are certain parts of the process which are distinct, and as protracted intervals may occur between them, we shall consider parturition as divided into three stages; the first stage terminating with the complete expansion or dilatation of the os uteri, the rupture of the membranes, and the discharge of the waters; the second stage including the complete expulsion of the child; and the third, which we regard as the most important, terminating with the detachment and expulsion of the secundines. In the first stage of this process our interference is not very frequently necessary; in the second we may have to put in practice the difficult, yet almost certainly efficient, rules of the art; but in the last stage of parturition, when danger from flooding arises, the life of the mother will almost entirely depend on the knowledge and promptitude of the medical attendant. It is a rule in midwifery to see a patient about to be confined as early as possible; for there may be a preternatural presentation; and from the rupture of the membranes, and the escape of the water, the favorable moment for turning may be lost previously to the arrival of the accoucheur. Flooding may endanger the life of the patient; and, in presentations of the feet, the expulsion of the child may have been so far accomplished, as that its head and body, being retained within the uterus, pressure on the umbilical cord may destroy the life of the child, when prompt obstetric aid might have preserved it. We should advise every accoucheur to carry about him the tincture of opium, a catheter, a tracheal pipe, and of course a lancet. It is scarcely necessary to illustrate this advice, by pointing out the various circumstances in which their employment may be required. Opium is invaluable in allaying the irritability produced by false or spasmodic pains; and every one is aware of the relief it affords in those necessary contractions of the womb occurring after almost every labor, with the exception of the first.

205. No one would employ obstetric instruments without previously ascertaining the state of the bladder, and this viscus is generally loaded with urine in difficult parturition. Where the os uteri is rigid, and the patient robust and plethoric, the abstraction of sixteen ounces of blood, at the commencement of labor, is frequently attended with marked benefit. The tracheal pipe is of great value in resuscitating the child, all other means being decidedly less efficient for this important purpose.

206. We have already alluded to certain changes indicative of approaching parturition; on these presumptive signs, however, we cannot give an opinion that the process has commenced; to do this with certainty we must examine per vaginam, which at the time of labor is denominated 'taking or trying a pain.' Women will scarcely ever allow this examination till they are convinced that labor has actually commenced, and then they are solicitous to be informed of its progress, and the probable period of its termination. The position in which this enquiry, and indeed the delivery, is to be conducted, varies amongst different nations, and in different districts of the same country. The German ladies are delivered while sitting, so that the full effect of the pains is exerted on the child's head over the centre of the os uteri. In Ireland they are frequently placed on the knees and elbows. But, in our own country, women generally repose on the bed upon their left side, with their knees bent, and drawn towards the abdomen; and this is sufficiently convenient for all common purposes.

207. This examination is to be conducted with the utmost delicacy and tenderness, as an unfavorable opinion of the accoucheur's skill and kindness may retard the progress of the labor. It may be needful to ascertain, per vaginam, even when labor is thought to have commenced, whether there be any disease of the uterus or of the parts in its immediate neighbourhood, whether a woman be really pregnant, to determine whether she be really in labor, what progress has been made, the character of the presentation, and whether the pelvis be well formed or distorted.

208. The author of this paper was once sent for to a case where the accoucheur had been up two nights expecting the birth of the child, and, on examination per vaginam, the uterus was found in its unimpregnated condition, the abdominal intumescence having arisen partly from adeps and partly from air. Dr. Blundell relates a case of this kind attended by a most unfortunate result, which we shall present in his own words:—'A gentleman called at my house and told me, not without earnestness, that he had under his care a case of labor about which he was very anxious. 'The mouth of the womb,' said he, 'is beginning to open, and I can feel the child; but the patient is somewhat weak, and labor makes but little progress.' On enquiring how long delivery had been protracted, a few hours was the reply, and he added that there was no very pressing symptom.

209. 'A meddlesome midwifery is bad' I rejoined; 'therefore it is better to wait, and not

unwisely and rashly distrust the best of accoucheurs, Nature, the mother of us all.' A day or two passed away, after which he called on me again, observing that his patient, still undelivered, was getting weaker and weaker, and that he wished me to give her a visit. On entering the appartment I saw the woman lying in state, with nurses, accoucheur, and all the formalities attending a delivery; one small point only wanting to complete the labor, which was, that she should be pregnant; for, although the practitioner had distinguished the head of the child in the uterus, there was in reality no fœtus there. A few hours afterwards the patient died; and, on examining the abdomen, we found the peritonæum full of water, but the womb, clearly unimpregnated, was no bigger than a pear; and thus it sometimes happens that we are called to reputed deliveries when, in truth, the patients are not even pregnant; and it is, therefore, one office, which, in natural labor, devolves on the the accoucheur to decide, in dubious cases, whether pregnancy exist or not.

210. The first stage of labor is generally the most tedious: it is attended by frequent, short pains, which are generally characterised as cutting and grinding. There is seldom much difficulty, when these have existed some little time (and we are not often called in before), to determine whether labor has really commenced; the greater difficulty is, to give a correct opinion as to the time which may be required for its completion. For this latter purpose great judgment and experience are required, and, even when these are fully possessed, it will be better, while we are careful not to discourage the patient, to lean to the side of doubt rather than of confidence. We may observe here, without attempting any explanation of the facts, that labors do really seem to proceed in regular periods of time, so that a labor which commenced at twelve o'clock at night, if not terminating at noon the next day, will frequently continue till twelve o'clock the next night. The remark is almost proverbial that uterine operation is suspended through the day, more especially in summer, to be again resumed during the night.

211. If it be really important to say precisely whether labor has begun, and to afford encouragement as to its progress, we must not form our opinion from the mere openness or relaxation of the os uteri during the absence of pain, but from the degree of dilatation which the accession and continuance of pain really produces. In cases where labor has been suspected, and where we have been allowed to examine, we have frequently found a considerable degree of relaxation, even where labor did not occur for some days or even weeks afterwards. Supposing the pains to continue, we may easily ascertain the extent to which the os uteri is affected; for if, from a degree of dilatation scarcely sufficient to admit the tip of the finger, the pain induces such uterine contraction as shall enlarge its disc to the size of a shilling, and by a few succeeding efforts to that of a dollar, we can entertain no doubt that the labor is really begun. If additional certainty be desired, the state of the membranes, during pain, will afford some criterion. If, from being flaccid, they become tense, and are protruded downwards, we may feel certain of the commencement of labor. If the membranes are ruptured, the same observations may be made on the head, which will advance and retreat during the pressure and inactivity of the uterine effort.

212. It is worth while to remark that women, especially if they have once gone through a difficult labor, will anxiously enquire 'if it be all right,' in other words, if the head is the presenting part; now, although this knowledge cannot always be obtained in so early a stage as that we are now describing, we may sometimes succeed in passing one or two fingers into the mouth of the womb, and, through the membranes, distinguish the presenting part. If we fail in this we may insinuate the fingers between the os uteri and the symphysis pubis, and if the vertex be presenting we shall easily feel it behind and above the ossa pubis.

213. A diversity of practice has obtained in the management of the membranes; some practitioners invariably leaving their rupture to the natural efforts, while others as invariably break them by artificial means so soon as they are within reach, and before the dilatation of the os uteri is accomplished. Of the latter practice we do not approve; the rule should be to leave their rupture to the natural efforts; the exception to produce it by artificial means. There are two instances in which the rupture of the cyst is fully justifiable; first, when, at the sixth or seventh month, there is an attempt to throw off the ovum entire and unbroken, in which case there may be most alarming hæmorrhage from the placental vessels, and the fœtus may probably be drowned in its own waters. And again, when the membranes are unusually tough and unyielding. Here we have known labor delayed several hours from an unwillingness to interfere with its natural progress. If, however, we find the membranes pushed down along the vagina, and protruding beyond the vulva, we may feel assured the os uteri is fully expanded; and we cannot err if, during the height of a pain, we force a stilette through the cyst, after which the child will sometimes be immediately expelled. Supposing the membranes to have been ruptured, and the liquor amnii to have escaped, the first stage of parturition is completed, and the very important duty of ascertaining the presentation devolves upon the accoucheur. It may be true in labors generally, and the remark is not rare in relation to the whole of obstetric practice, that it is of very little importance whether we know the presentation or not, as it is most commonly a natural one, and the child will be safely born independently of our assistance. But this does not always happen; the child may lie unfavorably; the aid of a skilful practitioner may be required, and complete success will very much depend on the bestowment of that aid before the uterus has fairly contracted itself round the body of the child. We cannot, therefore, be too particular in promptly ascertaining the presentation. When the head has passed through the os uteri, and the pains continue forcing and powerful, we must carefully watch its progress, lest, by the

suddenness of its protusion, the perinæum may be lacerated.

214. In first labors, and where there is a rigid unyielding condition of the softer parts, the protection of the perinæum is of great moment. It is not perhaps possible, and if it were so, it is not desirable, forcibly to prevent the descent and expulsion of the head; as rupture of the uterus may occur if the birth be too long delayed. To protect the perinæum we always employ the right hand, without the interposition of any napkin; kneeling by the side of the bed, the patient being in the usual position, we apply the naked hand over the perinæum, the fingers, supposing it to be a vertex presentation, reaching as far forward as the occiput. If the pains are not very vehement we merely request the patient not to force down during their continuance; if, however, there is a great degree of tension, laceration of the perinæum may occur, and then we resist the violent propulsion of the head, as much as we dare, by forcible pressure on all the parts of it within our influence. Lard and pomatum may be largely employed, as they not only lubricate the parts, but diminish the sensations of heat. The child generally comes into the world with the occiput forwards and the face posteriorly; and, when it has fully emerged, there is no necessity to hasten, by any efforts of ours, the expulsion of the shoulders. We ought ever to bear in mind that the less we interfere in natural labor the better. The ordinary efforts, in eight cases out of ten, will expel the shoulders, and the uterus will contract itself more regularly and effectively, and the placenta will be much more safely and quickly detached, where no attempts at extraction have been made. In the little interval which thus occurs we may examine whether the navel-string be round the neck of the child; and, where it is so, we may generally succeed in disentangling it, by gently drawing down another portion of it, and then passing it over the chin and face, thus setting it at liberty. If, as in an instance which lately occurred to us, the cord be coiled round the neck five or six times, although the birth may be a little delayed, we had better defer any attempt to disentangle it till the child is born, when it may be untwisted with the utmost facility.

215. In bringing away the child its abdomen should be kept, as nearly as possible, to the external generative organs of the mother. The reasons for this procedure are obvious. The cord, although usually two feet in length, may be preternaturally short; and, were the child to be suddenly removed to some distance from the mother, the womb might be inverted or the placenta partially detached. Both these events are obviated by an observance of the above rule. When the child has cried the first thing to be done is to tie the cord. This may be accomplished by a broad ligature, composed of coarse thread, or silk, several times doubled; for if the 'navel-strings,' as they are termed, be made up of only a few threads, they may cut the cord, giving rise to a fatal hæmorrhage. It is usual to apply the first ligature at a distance of three or four fingers' breadth from the navel; first making a single knot, and, having passed it round the cord in the same crease twice more, we may conclude by a double knot, firmly and tightly made. The second ligature is one of minor importance, and on the continent is seldom used; it may be applied at two or three inches, distance from the former, nearer to the placenta, and a single knot will suffice. In afterwards dividing the cord, by a pair of scissors, between the two ligatures, we must be careful not to cut it too near the first, as the ligature may afterwards slip, and endanger the life of the child. We wish to observe that when the child has cried vigorously, and moves about powerfully, we need not hesitate immediately to apply the ligature; if, on the contrary, its breathing is imperfect, and scarcely perceptible, from whatever cause it may proceed, we should defer the application of the ligature, and afford it the advantage of the placental circulation, till, by the warm bath and artificial respiration, we have fully established its independent vitality.

216. Before we attempt the delivery of the placenta, which constitutes the principal duty of the third and last stage of labor, we should ascertain whether there are any more children. This may be done by laying the hand upon the belly, and gently grasping its contents; if there be no other child, we shall find the abdominal parietes soft and flaccid, while the uterus, now become a circumscribed hard body, like a child's head, will be felt in the centre. Under this state of the uterus we need not hesitate to deliver the placenta, more especially as it will generally be found lying in the vagina. We may lay hold of the funis by the left hand, and passing up one or two fingers of the right, to the insertion of the cord, we may gently draw down, and we shall soon find the placenta passing through the os externum. Some practitioners are very particular in their directions about the membranes, and for ourselves we invariably attempt, by a very gentle withdrawal of the placenta, to insure the complete extraction of the secundines; thus obviating the painful contractile efforts which are subsequently made to expel them from the uterine cavity, and at the same time removing a source of annoyance, in the offensive smell to which, by their putridity, they may give rise. The bandage contrived by Mr. Gaitskell of Rotherhithe, which we have used, or a long towel, may be applied round the abdomen so firmly as to give a feeling of support, and, if there be any faintness or exhaustion, a few spoonfuls of brandy and water, flavored with spice, may be given. These, then, are the principal circumstances occurring in natural delivery, which, as it serves for the standard of all others, we shall briefly recapitulate. Let it be remembered that we have rarely to determine whether the woman be in a state of pregnancy, and that, from the existence of the grinding and sawing pains, we are still more rarely called upon to ascertain whether labor has or has not commenced. The rule is, not to rupture the membranes; the exceptions arising from their unusual toughness, or from a disposition prematurely to throw off the whole ovum. In every labor the presentation is to be made out as early as possible: if not previously at least

when the waters have passed off. In the first stage of labor little interference is necessary; but, when the head approaches the outlet, the perinæum should be carefully guarded. When the head has emerged, ascertain whether the cord be coiled round the child's neck, and, if it can be easily effected, disentangle it. The shoulders are not to be extracted by force, as the womb contracts more perfectly when allowed to expel the child by its natural efforts.

217. The fœtus is to be kept near the genitals of the mother till the cord is divided; and when this division of the funis has occurred ascertain that the ligature appertaining to the child is secure; and lastly, by care, and the application of the abdominal bandage, guard against uterine hæmorrhage.

218. *Observations on natural labor.*—We believe, in a state of nature, there is very little solicitude entertained, and very little preparation made for delivery. We find, from the accounts of various authors, that a seclusion of a few hours in some retired spot, or in a rudely constructed hut, is all which women living in a state of natural simplicity require for the completion of their labors; and after some slight ablutions, if religious custom does not demand their separation, they almost immediately return to their usual mode of life.

In countries where a high degree of civilisation prevails, and especially in Europe, parturition excites much attention, and is conducted with great care. Some patients prefer being delivered on a couch or bed distinct from that on which they are afterwards to sleep, a manifestly undesirable arrangement, as their removal after labor, especially if it has been severe, may be attended with syncope and alarming hæmorrhage. The bed is to be guarded; and this will be best effected by laying a large skin of red leather on that part of it where the hips are placed, and over this one or two blankets, or two or three sheets, so folded as to form a mass, which may absorb any fluid discharged during the labor; over these spread out another sheet, which, if fastened to the bed-posts, will keep the whole apparatus in its proper place.

219. The guarding of the bed is the office of the nurse, and with it the accoucheur has little concern; but it is necessary to touch on this familiar topic as, when the accoucheur is of puerile appearance, nurses will sometimes enquire, ex insidiis, in what manner he wishes the bed to be guarded. Now if he were at a loss here: if he were ignorant of the apparatus; if, surprised, he were to ask what the woman meant, adding perhaps surlily that the only guard necessary was himself, she would infer that he had seldom been at the bedside before, and presume that he was ignorant of more important matters. 'Parva leves capiunt animos.' The lying-in room should be kept cool, and the nurse and one or two female friends are sufficient for every purpose. Whispering, and indeed every circumstance calculated to excite alarm and apprehension, of which parturient women are extraordinarily susceptible, should be avoided. There is no reason why simple and nutritious food should be forbidden: stimulants and spice are injurious, excepting when the labor is tedious, and when exhaustion is delaying the delivery, in which case wine alone, or wine and water according to previous habits, may be allowed. Sleep should be encouraged in the intervals of pain; and cheerful lively conversation is productive of good.

220. The practitioner is occasionally to leave the room, to afford an opportunity for evacuating the bladder and rectum. In the first stage of labor, which is usually attended with frequent, sharp, cutting, and grinding pains, the woman need not be confined to the bed, she may walk about the room, and place herself in any posture which is most easy. In this stage there is no necessity to examine frequently, as the head cannot be expelled till the os uteri is dilated. Afterwards however, when the head is advancing towards the outlet, we must frequently inform ourselves of its progress, and prevent as much as possible that restlessness and irritability of the patient, which, even under Dr. Denman's management, was once the cause of laceration of the perinæum. Cramps, which are occasionally arising from pressure on the obturator and sciatic nerves, are favorable, inasmuch as they indicate the rapid descent of the child through the pelvis. Vomitings, shiverings, and rigors, are often occurring during the dilatation of the os uteri; and, as they are proofs of the sympathy of the system with the uterine action, they need not excite alarm. It is seldom necessary to employ any remedies for their removal: if the vomiting be very severe, you may give the saline effervescent mixture; and if symptoms of pyrexia, with affection of the head, follow the rigors, more especially if the pulse be high and the arteries about the head throb, the abstraction of sixteen, twenty, or even five-and-twenty, ounces of blood from the arm will be very desirable.

221. Children, though not dead, are sometimes still born, or they are incapable of crying, and of manifesting other indications of vitality. This effect is generally produced by pressure on the umbilical cord, or, where the head has been long jammed in the pelvis, it may arise from compression of the brain. Three modes of resuscitating the child, when still born, have been proposed: pressure on the ribs, blowing into its mouth, and the performance of artificial respiration by the tracheal pipe. The first is to be effected by pressing down the ribs, which are very elastic, so as alternately to enlarge and diminish the capacity of the chest, thus keeping up an imperfect artificial respiration. This mode of procedure we have adopted several times, but in vain, as it is not probable that much air enters the lungs. The second method, or that of blowing into the mouth is very inefficient, as, with the utmost care, it is doubtful whether you can inflate the pulmonary cells. The tracheal pipe is the only instrument by which we can so effectually fill the lungs as to afford any satisfactory prospect of resuscitating the child. The warm bath may ever be regarded as a most powerful auxiliary. Le Gallois removed the head of a rabbit and secured the vessels of the neck; the animal seemed dead, but, when artificial respiration was commenced, signs of vitality were soon

apparent. The heart acted; the circulation was again carried on; and muscular irritability was renewed throughout the whole system. Thus in a decapitated animal, by means of artificial breathing, he maintained for one, two, and three hours active vitality. No stronger proof can be adduced of the efficacy of pulmonary inflation, in renewing and supporting the action of the heart and arteries. In performing this artificial function for new-born children, it has been frequently observed, that, while the respiration was continued, the cord pulsated, ceasing to beat in a few seconds when the operation was suspended. The tracheal pipe, is a little tube of silver, designed to pass into the trachea, its end closed like a catheter, with a long broad fissure on either side, to give free vent to air and mucus. In order to introduce this instrument, pass the forefinger of the left hand down upon the root of the tongue, and into the rima glottidis; and then, taking the tube with the right hand, slide it along the surface of the finger, till reaching the rima, when the tube is to be inserted into the trachea, immediately the finger is withdrawn, afterwards feeling on the front of the neck, whether the instrument is lying in the trachea or œsophagus. This done, the child may be taken into the hands of the accoucheur, and from his lungs the lungs of the child may be inflated. Operating in this manner the artificial respiration may be executed with the best success. A woman, whose case we recollect, having been run over by a coach, was carried into St. Thomas's Hospital, and died in a few minutes after admission. She was at the end of pregnancy, and the Cæsarean operation was performed by Mr. Green in thirteen minutes from the last respiration of the mother; the child was taken out, and, in fifteen minutes from the last respiration, Dr. Blundell began the artificial respiration. During fifteen minutes longer it was continued, ultimately completely resuscitating the child. Mr. Tomkins of Yeovil once used resuscitants for an hour and five minutes by the watch, before obvious signs of life appeared, the child recovering at last and living for some time.

222. *On hæmorrhage occurring immediately before or immediately after the birth of the child.*—We have already remarked that the third stage of parturition is the most important, and involves the most momentous consequences. The birth of the child, in natural labor, is generally accomplished by the natural efforts; and, if we except the protection of the perinæum, no exertion is demanded from the practitioner, beyond what sound discretion will readily enable him to bestow. This, however, is far less frequently the case in relation to the placenta; for, without any error on the part of the accoucheur, partial detachment of this viscus, giving rise to alarming hæmorrhage and irregular contraction of the uterus, detaining the placenta in its cavity, may occur. After a well conducted natural labor we generally find, in fifteen or twenty minutes from the birth of the child, that uterine pain is again returning; and, if we pass the finger along the course of the funis, we shall probably discover the placenta lying either low down in the vagina, or at the os uteri. In these circumstances, the slightest bearing on the funis secures the birth of the placenta; and, as its situation in this case presupposes the complete contraction of the uterus, we need only remark that its extraction is to be conducted with delicacy and care. The contraction of the womb is the basis on which we must found all rules for the extraction of the placenta, as well as all pleasing expectations of the future safety of the patient. By this process the womb not only diminishes its internal surface, but, in a greater or less degree, it acts upon and expels its contents, and subsequently secures itself from the risk of hæmorrhage and inversion. The various conditions in which the uterus is found, after parturition, are dependent on the more or less powerful exertions of this principle. Where we find the uterus circumscribed, round, and hard, we know that contraction has taken place; and that neither flooding nor inversion is likely to occur. Where, on the contrary, the uterus is large, lax, and soft to the feel, its parietes being so ill defined as scarcely to enable us to ascertain its precise dimensions, we must proceed with the utmost caution. There are other conditions, varieties of these, in which the womb may after delivery be found, but as they will only require a modified treatment we shall not particularly describe them. A diversity of management in these different states has been instituted; and, observing the fatal consequences which followed the artificial separation and delivery of the placenta, Buysch, Hunter, and Denman recommended in all cases after the birth of the child, that the expulsion of the placenta, like that of the fœtus, should be committed to the natural powers; believing 'that the same natural powers which were adequate to expel the child, were also adequate to expel the placenta.' And we can easily conceive where women live in a savage and barbarous state, that little danger will ensue. Experience has however proved that, if the expulsion of this important viscus be left to the unaided powers of uterine contraction, patients frequently die. The practice has been tried both in Holland and in this country, and is now we believe entirely laid aside. Different rules have been prescribed as to the precise time when artificial assistance is to be rendered. Hunter and Denman regulated their interference according to time; and, if the placenta did not come away within four hours after the birth of the child, they conceived themselves fully warranted in the employment of manual assistance.

223. Other practitioners have formed their criterion of interference from the degree of pain, and the situation of the placenta in the uterine cavity. These rules are all individually good, but if a determinate one is to be formed, or as near an approach as possible to a fixed law of procedure is to be attempted, much freedom must be allowed to the exertion of individual judgment and discretion. In the slighter cases of hæmorrhage after labor we should not enjoin a hasty delivery of the placenta; if we wait twenty or thirty minutes, the uterus will in some degree have recovered its tone, the circulation of the mother will be less hurried, and the removal of this viscus will be accomplished with less subsequent risk. We need scarcely say that, before commencing any attempt at removal,

we must ascertain distinctly whether there be another child. If there be twins, there may be a common placenta, and its abstraction before the birth of the other child might be productive of suffocation to the unborn fœtus. Having determined to extract the placenta, and having placed the woman on her left side, we may lay hold of the umbilical cord with the right hand, passing two or three fingers of the left into the vagina, so as to secure a bearing on the body of the placenta; and, if the pains are occurring at intervals, it is better to wait for and cooperate with these than to extract without them. If, however, they are wanting, we must draw down steadily in a direction from the umbilicus to the coccyx, securing each advance by a firmer hold of the funis: and, if the circumstances are such as to justify its removal, we shall seldom find much difficulty. We have now described the most simple case of extraction of the placenta, where there can exist little difference of opinion as to the propriety of the measure. And we would here again remark, that the placenta is much more readily and speedily separated from its uterine attachment, and that the uterus itself is much more likely to be found low in the abdomen, firm, circumscribed, and well contracted, if the latter part of the labor has been deliberately performed, than when, from an anxiety to terminate the process, the body and lower extremities of the child have been manually extracted, during the absence of uterine pain. It will occasionally happen, after the expiration of an hour or longer from the birth of the child, and when by external pressure, and the exhibition of some slight stimulant, we have endeavoured to excite the contractile efforts of the uterus, that it still continues high in the abdominal cavity, flaccid, ill-contracted and of large size. This condition may exist under two states of the uterus in relation to the placenta. The placenta may either be separated from its uterine attachment, and, remaining loose, cannot be excluded out of the cavity of the womb from a deficiency of contractile effort; or it may be morbidly or schirrously adherent to its internal surface, in which case we shall wait in vain for its natural expulsion.

224. We have already remarked that the placenta cannot safely be left for an indefinite period in the womb; and when we remember the solicitude of the patient and her friends, and the painful suspense which a retained placenta must ever excite in the mind of the accoucheur, and that it may be morbidly or schirrously adherent, we cannot entertain any doubt as to the propriety of its safe and timely removal. Dr. Ramsbotham, whose Practical Observations on Midwifery deserve a place in the library of every obstetric practitioner, says, that 'the introduction of the hand into the uterus, after the birth of the child, is, to use the mildest language, a harsh and severe measure: it always gives considerable pain, and it cannot be practised with impunity without some risk, present or future.' It must be acknowledged that this opinion is well-founded, that a meddlesome midwifery is bad, and yet, if any circumstances justify this measure, the retention of the placenta with loss of blood especially does so. An accoucheur cannot commence this most serious proceeding with too powerful an impression of the delicacy of the parts on which he is about to operate; and yet, if he conduct the extraction slowly and skilfully, he will not often have to regret its performance. We are somewhat disposed to believe that a share of the difficulty and danger, consequent on this operation, may depend on the length of time which is so often, through timidity or dread of the consequences, allowed to elapse before the commencement of the manual extraction; the womb having had time firmly to contract itself around those contents which are now to be considered as extraneous bodies, and as obstacles to its natural diminution of size. 'It will rarely be necessary to exceed two hours, before recourse be had to this proceeding; more frequently its necessity will be obvious before the expiration of this time; indeed, on an average of cases, it will be found that, if the placenta be not thrown off within one hour after the birth of the child, it is detained by some unusual cause. If hæmorrhage, or other pressing symptoms, suddenly intervene, an earlier removal will be required, otherwise every thing like hurry or haste ought carefully to be avoided.' Vide Dr. Ramsbotham's Observations, p. 57.

225. If then the placenta be retained after labor, by that irregular action of the uterus which has been denominated the hour-glass contraction, and hæmorrhage supervene, or if we have reason to suspect its morbid adhesion to the internal surface of the uterus, from the continuance of this latter organ in the state we have already described, and, from our inability to trace the progress of the end to its termination in the placenta, there is no other alternative than by the introduction of the hand to overcome in the one instance the contraction, when the placenta will generally be immediately expelled; and in the other, by the same means, carefully to separate its morbid adhesions. In order to effect this purpose the left arm should be bared, and well smeared with lard, the woman having been previously placed on her left side, with her knees drawn up towards the abdomen, and her nates at the edge of the bed. The accoucheur may sit on a low chair; or, which is much more convenient, he may kneel at the side of the bed. Having accomplished the introduction of the hand into the uterus, he will soon discover the cause of retention; if it arise from irregular contraction, whether it be of the longitudinal kind, or globe-like, he may advantageously apply the right hand over the uterine tumor externally, thus aiding his operations by steadying the womb, and preventing any rolling motion; the contracted part is to be slowly and cautiously dilated, till the hand can obtain admittance so far as to include within its grasp the whole or greater part of the placenta, when it may be gradually withdrawn. If the placenta be found partially or generally adherent to the inner surface of the uterus, the fingers must be cautiously insinuated between its edge and the womb, and carried forward till the whole mass is separated, when it may be removed as in the former case. It will not unfrequently happen that the contractile

efforts will be so violent as to impair the sensibility of the fingers, and indeed of the whole hand; in this case we may allow it to remain for a short time at rest in the uterine cavity, but we should, if possible, avoid its retraction, as its reintroduction will give great pain, and be attended with renewed risk. If the placenta be retained merely from torpor of the uterus, which often happens after laborious and protracted delivery, the stimulus of the hand within its cavity will generally induce a sufficient return of contractile effort for its entire expulsion.

226. We have now dwelt at length on those floodings and their treatment which are occurring between the birth of the child and the expulsion of the placenta; and we are from experience disposed to believe that they generally arise from its greater or less adhesion to the uterine surface; nor are we aware of any measure to which we can look for safety, but to the introduction of the hand, inducing thereby contraction of the uterus, and the consequent expulsion of the placenta. We are not always so fortunate as to secure contraction, even where we have succeeded in bringing away this adherent viscus; for, a little time ago, we were compelled to watch a patient four hours in these circumstances, and during the whole time to maintain a griping, grasping action on the uterine parietes, thus preventing hæmorrhage.

227. *Flooding after the birth of the placenta.*—The first circumstance requiring attention after the expulsion of the placenta, supposing we are satisfied that there is not another child, is to insure firm and permanent contraction of the uterus. The patient is now to be kept remarkably quiet; and it is important, if she be prone to hæmorrhage, that stimulants should not be given. The condition of the uterus should be frequently examined, and even the slight grasping of its parietes by the hand will often be sufficient to maintain it in a state of firm and satisfactory contraction. The bandage is to be applied round the region of the uterus, tightened so much as to afford an agreeable feeling of support. It may so happen, however, that notwithstanding every precaution the uterus may become suddenly relaxed, and even under a very slight degree of relaxation, if the force of the circulation is extrordinarily great, it may, according to some cases published by Dr. Gooch, in the Medico-Chirurgical Transactions, be able to overcome the ordinary closure of the orifices, and thus a profuse hæmorrhage may arise, although the uterus be contracted.

228. Dr. Gooch has also noticed the fact of the alternate contractions and relaxations of the uterus in hæmorrhage, which every practitioner in midwifery must frequently have met with. Supposing the hæmorrhage to have been considerable, and the patient in a state of alarming exhaustion, with bleached face, and scarcely a perceptible pulse, it is evident there is no time to be lost, if the uterus does not contract, the flooding may recur, and the patient may soon be placed beyond the reach of remedies. In these cases, if the uterus is large and flaccid, we must not hesitate, after the exhibition of some powerful stimulant, as brandy or rum to apply cold vinegar and water to the pudenda and loins, and pounded ice to the abdomen. We have indeed seen cases where these remedies were not efficient in restraining the hæmorrhage; and we have in several instances, and with the best effect, dashed cold water from a considerable height on the naked abdomen. We shall subjoin the following cases as illustrative of the vigorous treatment which these floodings demand; we could add many more of the same kind, but here, and in subsequent parts of this treatise, we shall generally be satisfied with the insertion of one good example, illustrative of the practice recommended, as we feel assured where the cases are genuine, and the treatment correct, practitioners will verify and apply the rules by a reference to their own experience. Our great aim is to afford information which will be available at the bedside of the patient, and to render our observations essentially practical.

229. On the 4th of November, 1823, Mrs. ——, aged twenty-three, after a lingering labor of twenty-eight hours, was confined of a girl, her first child. The head was large, and from extreme rigidity of the parts, and the severity of the expulsatory pains, she had suffered greatly before its birth; previously to the extraction of the placenta the abdominal bandage was applied, and she expressed much pleasure at the support it afforded. After fanning her, and giving a little simple gruel, the pains recurred, and the placenta was low down in the vagina before its extraction was attempted. Immediately after its removal she lost perhaps a pint of blood; but the uterus contracted well, and she remained tolerably tranquil for twenty minutes. The uterine parietes were now most suddenly relaxed, and an alarming quantity of blood was impetuously pumped out. Cloths, wetted with the coldest water, were thrown rather forcibly on the abdomen, pudenda, and thighs; a draught of the coldest spring water was swallowed, the bandage was tightened, and the uterus griped by the hand. These measures restored her from a state of collapse and syncope, and induced firm contraction of the womb, which might now be felt as large as a child's head, and almost as hard. She progressed very satisfactorily for a full hour, when, having left the room for a few minutes, we were hastily summoned to the patient, whose appearance was very alarming. The eyes were closed, the lips colorless, her extremities cold and thrown out, as in the last act of life, and the action of the heart was scarcely perceptible. Several pints more blood had been lost, and, without waiting a moment, we dashed from a considerable height a large ewer full of cold water on the naked abdomen; poured several wine-glasses full of nearly pure brandy down the throat, and determined to trust no longer to the continuance of uterine contraction. The uterus was once again small, and both the hands of the accoucheur were now applied to its parietes, keeping up such griping pressure as was necessary to insure a continuance of its contractile action. By the aid of the nurse, and two female relatives of the lady, we maintained this manual pressure for six hours, after which no further hæmorrhage

ensued. This patient had a very protracted and painful recovery.

230. It is worthy of remark, in this case, that the hand was not introduced into the uterus, and, where coagula are not preventing the contraction of this organ, we think the means now described will generally put a stop to the hæmorrhage without resorting to this objectionable and hazardous proceeding.

231. Mrs. ——, aged twenty-seven, was confined on the 4th of July, 1824, of her first child, after a labor of only a few hours duration. The practitioner in attendance, before we saw the patient, stated that the uterus contracted well after the expulsion of the placenta. Four hours after labor the nurse discovered she was flooding, and requested the attendance of her accoucheur, who applied cold cloths, and, supposing the flooding to have stopped, took his leave. On examination of the abdomen we were astonished at the bulk of the uterus, and from the exhausted and powerless state of the system, we were convinced that the internal hæmorrhage was large and alarming. The hand was passed into the uterine cavity, and at least three or four pints of coagula were removed, after which the uterus powerfully contracted. This did not continue long; relaxation again occurred, and more blood was lost. Brandy, and the griping of the uterus for two hours, permanently restrained all further hæmorrhage; of course the abdominal bandage was applied. This lady continued in a precarious state for some days, and was very long in regaining her strength.

232. For patients predisposed to hæmorrhage during labor we have been for some years in the habit of prescribing a less nutritious diet for one or two months preceding confinement; and in one case, which it is not important fully to detail, we have, before two successive confinements, taken away sixteen ounces of blood with decided advantage.

233. Some able remarks of Dr. Gooch in the paper to which we have already referred, so entirely coincide with circumstances of daily occurrence, that we shall present them in his own words. 'I could easily understand that a contraction of the uterus, which would preclude hæmorrhage in the ordinary state of the circulation, might be insufficient to prevent it, during violent action of the blood-vessels; and the inference I drew was, that in cases of hæmorrhage dependent not on want of contraction of the uterus, but on the want of tranquillity of the circulation, a mode of treatment which would produce a cool skin and a quiet pulse would be the best for presenting a recurrence of these floodings. How often a disturbance of circulation plays an important part in uterine hæmorrhage it is difficult for an individual to know; but I suspect sufficiently often to deserve the especial attention of practitioners. I advise them, when they meet with patients subject to hæmorrhage after delivery, to notice the state of the circulation before labor, and, if disturbed, to employ means for tranquillising it before labor comes on. I advise them during labor to use cordials cautiously, lest the placenta should separate during an excited state of circulation. I advise them, after delivery, though the uterus may feel contracted, to be slow to leave their patient if the circulation be greatly disturbed.'

234. In the concluding part of this paper Dr. Gooch recommends a practice, in which, without greater qualification than he has annexed, we cannot coincide. We refer to his opinion 'that when hæmorrhage occurs after the removal of the placenta, the quickest way to stop it is to introduce the left hand closed within the uterus, applying the right hand open to the outside of the abdomen, and then between the two to compress the part where the placenta was attached, and from which chiefly the blood is flowing.' We are aware that, in alarming and desperate floodings, any measure, however severe, is justifiable; the intention is to save a life which appears on the very point of extinction, and after consequences must yield to this momentous purpose. We do not deny that as a 'dernier resort' the carrying of the hand into the uterus may be absolutely necessary; but we are equally convinced that the griping or grasping pressure of the womb commenced immediately after the birth of the placenta, when there is an habitual proneness to flooding, or when the contraction of the uterus is unsatisfactory, will generally supersede its employment. The introduction of the hand into the uterine cavity is always attended with risk, and it cannot be less so when, owing to the exhausted and powerless state of the system, the uterus and vagina may easily suffer rupture or laceration. It may too be urged against this practice, when it is performed during syncope or approaching collapse, that it must of necessity destroy coagula or clots which are forming about the mouths of the bleeding vessels, and may thus originate fresh hæmorrhage. Briefly then to recapitulate what we have advanced, on this deeply interesting subject, we remark that, immediately on the birth of the child, flooding may arise; that it may depend on torpor of the uterus, rendering it incapable of expelling the placenta, or on the schirrous or otherwise morbid adhesion of this viscus to the internal uterine surface; that a variety of circumstances as to the time and manner of interference are demanding consideration; and that, while the bestowment of hasty and unnecessary assistance is to be deprecated, it should not be withheld for more than two hours, and when the hæmorrhage is alarming immediate extraction is necessary.

235. After the birth of the placenta, dangerous floodings, and these are by far the most numerous, may also arise; notwithstanding every effort to tranquillise the circulation, and to induce uterine contraction. In these cases we are to apply the abdominal bandage, and cold washes to the pudenda, thighs, and loins, to maintain a constant griping pressure externally on the uterine parietes, and to support the vital powers by stimulants, if necessary, in large quantities; if these fail, we may inject cold water into the uterus, and as a last expedient, by the introduction of the hand into its cavity, excite contraction; in addition to all measures, we must strictly enjoin wherever there is serious flooding the most entire and absolute rest, not even allowing a change of posture if it can by any means be avoided.

236. *On transfusion.*—The subjoined remarks are copied from the lecture of Dr. Blundell on this subject, as published in the Lancet.

237. If transfusion, with all its defects and excellencies about it, should be found hereafter to be as safe as other received operations of surgery (venesection for example), it may then, I conceive be performed in those cases where there have been large discharges of blood from the uterus, although the danger arising from the inanition may not be very imminent. In the present state of knowledge, however, and until we have further proofs of its efficacy and safety, in cases which are not desperate to appearance, I should not recommend the operation of transfusion; but if you have under care a patient in whom the flooding has been copious, in whom further the womb has been emptied, and the hæmorrhages stopped; should this woman, as I have myself on several occasions seen, be sinking gradually into the grave, so that, even to those who have seen much of floodings, the case appears to be without hope: under such circumstances, I affirm, that it is highly proper to have recourse to the operation of transfusion, provided we are competent to perform it.

238. In performing this operation, which I shall presently explain to you more at large, it is not necessary you should inject any very copious quantity of blood; for, in the present state of our knowledge, it would be unwise to endeavour by large injections to raise the patient at once from a moribund condition to a state of vigor. What is the ordinary average measure of blood required, in order to turn the trembling balance in our favor, has not as yet been clearly ascertained by facts and observations. From what little I have observed, however, I should suppose that from half a pint to a pint may be considered as a very ample supply; and I feel persuaded that, of those women who have sunk under floodings, the greater number would not have been lost, could they but have retained the last ten or sixteen ounces of the blood which they have lost.

239. Although I have said an operation of this sort is not to be rashly prescribed, and although in the present state of knowledge it ought to be confined to those cases only which, according to our honest judgment, must be considered as desperate without it; yet let me add further, in the way of caution, that where there is need of the operation it is obvious the sooner it is performed the better. I have myself seen two women die, whose lives, I feel persuaded, might have been preserved to society, had transfusion been more promptly begun. Anxious to refrain from the operation, while there remained a hope of life without it, I delayed the use of the syringe so long that, before transfusion could be commenced, the patient in each instance was breathing her last.

240. To give you a summary then of what appears to me to be important on this point, I conceive that under the large eruptions of blood from the uterus, if well managed, in general (say in nineteen cases in twenty) your patients, though they may alarm and shake your nerves, will nevertheless ultimately do well, and transfusion will not be required. I maintain, however, notwithstanding what is asserted to the contrary, and I boldly maintain, for I am irresistibly borne out by facts, that under the best and most judicious treatment, and certainly under treatment of average excellence, dissolutions may occur, sometimes so suddenly that you have not time to act; more frequently in a gradual manner, so that you see the patient sinking slowly, by little and little, into the grave. Now, in cases of this kind, when the patient is sinking gradually, I am not sure that transfusion might not be proper, even though the ovum were still in the uterus; but certainly such cases are not adapted to the splendid success of the operation, for, so long as the womb is unemptied, the bleeding may return, and the blood may be lost again as soon as it is injected; but when the uterus has been emptied, and the hæmorrhage has been stopped (and of all the cases these are the most common); then under the conditions stated the syringe should be tried, provided the case be obviously desperate without it; provided too you feel conscious that lying in the situation of the patient you would wish the essay to be made on your own person. The operation once obviously necessary, beware of delaying it too long; beware of subjecting yourselves to the painful mortification of seeing your patient perish at the entrance of the port; sink at the very moment when you are at length prepared with the very operation that might have saved them. From six to ten ounces of blood will probably be sufficient to turn the wavering balance in our favor. From one or two friends, males in preference to women, this supply may be obtained; a large injection is not desirable; reaction of a lively kind will sometimes come forward on the subsequent day. Adhere to these rules, and you cannot wander far from the line of duty; and let me ask now where is the folly, where the enthusiasm of all this?

Class I. Order 2.—*Lingering labor.*

Dystocia diutina: Merriman.—Lingering labor: Smellie.—Slow and painful labor: Watts.—Lingering and perplexing labor: Cooper.—Tedious labor: Burns. Class IV.—Difficult (but natural) labor: Hogben.—Dystocia protracta: Young's Nosology, Class V.

241. When we consider the circumstances attendant on human parturition, that certain expulsory powers are required to bring about the birth of a child, which of necessity implies a principle at least of passive resistance, we can easily understand that on the degree of harmony or want of accordance existing between the two will depend, in a great measure, the natural or difficult character of labor. We accordingly find that lingering labor, so called from being protracted beyond twenty-four hours, and yet ultimately terminating with safety to the mother and without instrumental aid, is mainly dependent on two causes: defect of pains, or in other words deficiency of the expulsory power, and increased resistance to the passage of the child.

242. Defect of pains or expulsory power may arise from original or acquired weakness of system, and in labor it will be characterised by unsa-

ficient, irregular, or partial action of the uterus. Increased resistance to the passage of the child is principally produced by the rigid and undilatable condition of the os uteri and external parts, the large size of the fœtal head, and the want of conformability in its bones, or on the small size of the pelvis, associated with an unyielding condition of the os coccygis. Monstrous formations of the fœtus do not admit of the application of regular rules; for, when these unfortunate deviations do occur, they are not constructed on any established principles, and their management must of course be left to the skill and judgment of the practitioner. Extreme distension of the uterus by the liquor amnii, and extraordinary thickness of membranes enclosing it, admit of such easy remedy, by the measures already alluded to, that we shall not bestow upon them a distinct consideration.

243. In the treatment of lingering labor, where there is deficiency of pain from original or acquired weakness of system, great scope is afforded for the exercise of the patience and passive firmness of the accoucheur. The natural powers are often distrusted, where they ultimately prove themselves capable to accomplish the delivery; and where, if they have not been interfered with, the subsequent recovery will be very satisfactory. We cannot form a correct opinion of the degree of pain required in different cases of labor to complete the delivery. In some women the most powerful and continued efforts are necessary for the birth of the child; while in lingering cases, where there seems to have been scarcely any really good pains for twenty-four hours, we nevertheless find the head protruding at the external parts; and one or two rather severe efforts are sufficient for its expulsion. We are always unwilling to hasten the progress of lingering parturition, if symptoms of debility, of cerebral affection, or of pressure on the parts themselves, do not indicate the necessity for interference. In some patients there is so little irritability, so little anxiety about the protraction of the labor, if the circumstances of delay are candidly and judiciously stated, that we are not at all induced to employ any stimulant remedies. In other women, the converse of this statement is true, and they will more quickly require assistance.

244. The patient's strength must be supported by mild nourishment, such as beef-tea, veal-broth, &c. These, however, so often produce flatulence and uncomfortable distension of the stomach, that small quantities of solid food, as sandwiches, at proper intervals, are sometimes preferable. Dr. Hunter used to say in his lectures, that he had attended a patient three days and nights and one whole fourth day, the woman crooked and the child large. She lived all the time on tea and gruel only. Dr. Merriman appends the following remark, 'had the doctor allowed this patient cordials and stimulants, with a view of keeping up her strength, is it probable that the labor would have terminated so favorable?' We think that it would not; still there are cases where stimulants may be exhibited, and for this simple reason, that instrumental aid will be required if some safe impulse cannot be given to the uterine system. We are decidedly opposed to wine, or stimulants in any form at the commencement of labor, or to their injudicious exhibition during its continuance; but we have seen the happiest effects result from this treatment, in the protracted stages of lingering labor. We were lately called to a case, and requested to use instruments, where the patient had been forty-eight hours in labor of her first child; the parts had been rigid, and sixteen ounces of blood had been early abstracted; the head had rested many hours in its present situation below the brim, and pressing on the perinæum, and the pains were ineffective and at distant intervals. Here we encouraged the patient to hope for a safe delivery, ordered some solid nourishment, and port-wine negus; and in three hours the labor was safely completed, although the child was dead. The bowels should be cleared of feculent or other accumulations by mild aperients and clysters; the patient is not to be fatigued, and if the pains merely harass, and do not benefit her, she may take ♏xv. vel ♏xx. of the tincture of opium. Much larger doses than these have been recommended, and we have seen their bad effect in an entire suspension of uterine action.

245. In those cases where the os uteri is nearly or fully dilated, and where the head has remained in one position some hours, with ineffective pains, we may consider the action of the uterus arrested; and, if the means already pointed out are not successful in restoring its contractile energy, we may have recourse to the ergot of rye, which is universally allowed to increase the uterine pains, and consequently to hasten the delivery of the child. It is given in infusion; a dram, infused in a teacupful of boiling water for fifteen minutes, is the usual dose, and, if it should not produce any effect within an hour, it may be repeated. It has been considered very destructive to the life of the child; but from what we have seen of its effects, and from the extensive enquiries we have made, we are inclined to think that the death of the child in many of the instances ought in fairness to have been attributed to other causes, as the long continuance of the labor, pressure on the umbilical cord, &c. It does sometimes fail to produce any good effect; but this is common to all remedies; and when given before the head is in the cavity of the pelvis during rigidity of the softer parts, or where there is any deformity, we can easily conceive that the powerful contractive efforts to which it gives rise may induce serious injury both to the mother and the child. A most extraordinary circumstance, in relation to the ergot, is noted by Dr. Bibby of New York, that where the fœtus has been some time dead, and putrefaction to any extent has taken place, the remedy is altogether inert. In no case where it has been used has hæmorrhage occurred, and in natural labor when hæmorrhage does occur, it has been employed with great advantage.

246. Increased resistance to the passage of the child, which we have already enumerated as one of the principal causes of lingering labor, may be produced by the rigid and undilatable condition of the os uteri and external parts. These

are very trying cases, for the pains are sometimes so frequent and powerful as to render it necessary, for the satisfaction of the patient, that the accoucheur should be in attendance for hours before his assistance is really required. We are fully aware how constantly rigidity is the cause of tedious labor, and we believe that its treatment has not obtained perhaps all the consideration to which it is entitled; yet we cannot concur in the following opinion of Dr. Dewees, a distinguished American practitioner. See a valuable Practical Treatise on Midwifery, by Dr. Dewees, 1825. 'Writers have but very imperfectly considered the rigidity of the soft parts as a cause of difficult or tedious labor; some, indeed, do not mention it, and others do so merely en-passant. It is so common a case that every practitioner must have met with it; but it has failed to make a proper impression, because time and severe suffering have eventually overcome it, though not always with safety either to mother or child.' We cannot perceive that Dr. Dewees has thrown any new light on this subject; he has certainly recommended larger abstractions of blood (a practice previously enjoined by Mauriceau to a moderate extent), than we should feel disposed to adopt, unless the rigidity was extreme, the pulse very full and frequent, and the general tendency to inflammation and fever marked and decided. We trust we shall never hesitate to adopt the boldest and most vigorous treatment, when absolutely required; but as partial fatuity, in our opinion, has often resulted from the unnecessarily large abstractions of blood in apoplectic disease, so a painful and protracted recovery, with its attendant evils, will, we think, often occur, from bleedings to the extent of thirty forty, or even fifty ounces in these cases.

247. Were we called to a patient with rigidity of the softer parts, whose previous labors had been protracted from the same cause, we should consider venesection as the first in the series of remedies. In rigidity of a moderate kind, or during a first labor, we should first of all empty the rectum, whose feculent accumulations we have frequently known to obstruct labor. The bladder should not be distended, and the erect posture, short of fatigue, may be maintained; every thing is to be avoided at all likely to produce fever. Tea, toast and water, barley-water, milk and water, or veal-broth, may be taken; and the apartment should be airy and cool. We have twice rubbed in the belladonna, as advised by Dr. Conquest, but without any benefit: we have many times been much gratified with the effect of opiate clysters, or suppositories introduced into the rectum, even after opium has been taken internally, without any apparently good effect. Opium should not be given until the bowels have been relieved, and of course, if bleeding has been previously employed, it will be exhibited under the most advantageous circumstances.

248. The author of this paper some time since attended Mrs. ——, aged twenty-two, in her first confinement, the edges of the os uteri being much attenuated, very hot, not at all moist, nor disposed to dilatation. There was neither fulness of pulse nor heat of surface, beyond what is commonly occurring in the commencement of labor. The bowels were fully relieved by castor-oil, and the pains had been tranquillised by thirty minims of the tincture of opium. After an hour's sleep, she awoke refreshed, and the pains recurred. Eighteen hours had now elapsed since the commencement of the labor, and there was no alteration in the os uteri. A drachm of the extract of belladonna was rubbed about the cervix and os uteri, but, after waiting for two or three hours, there was no perceptible effect. The pains were very vehement and forcing, but the attenuated edges and heated condition of the os uteri still continued, and it was not dilated more than enough to admit the tip of the finger. A clyster composed of linseed tea and sixty minims of the tincture of opium was thrown into the rectum: it remained nearly an hour, and immediately on its expulsion two grains of solid opium, softened by mucilage, were insinuated into the bowel, just beyond the sphincter ani; very shortly afterwards the condition of the os uteri began to change, and, before the expiration of three hours from the giving of the injection, the head was protruding at the outlet. We have frequently since this period adopted the practice of giving opiate clysters and suppositories, and always with decided advantage.

249. Some practitioners, says Dr. Merriman, are fond of introducing lard or pomatum, in order to induce relaxation, but this never does good, unless the rigidity is confined to the vagina, or external parts, it may then be frequently used with advantage. The best method of using greasy applications in such cases is to have very good tallow, scraped and rolled up into a ball, about the size of a nutmeg; this should be carried by the finger as high as possible into the vagina; here it gradually dissolves, and is dispersed over the whole surface. It answers best in those cases where the natural mucus of the parts is either not duly secreted, or has been accidentally or incautiously separated.

250. The large size of the fœtal head, and the diminished capacity of the pelvis, oppose nearly the same obstacles to the full effect of the expulsatory powers of the uterus. It is manifestly impossible exactly to predetermine in what proportion the diminution of capacity of the pelvis may consist with the passage of the child's head, reduced as much as possible in bulk by the overlapping of the cranial bones; but we have seen the fœtal head so altered in shape, and so diminished in bulk, by the operation of this principle of conformability, as to induce us to wait for many days, provided no alarming symptoms arise, before we should class it amongst the difficult labors, and avail ourselves of instrumental aid. The elongated, squeezed, and sugar-loaf heads, which we so often see, and where although much compressed the child is yet born alive, must induce great confidence in the natural powers. It is a common remark, and without entirely assenting to its truth, we may repeat it here, that, after the most severe labors, women frequently have the best recoveries. Let the patient avoid stimuli, except by the permission of her medical attendant; let

her mind be tranquillised by an assurance of the probability of her welfare, and labor will very often terminate safely and well.

251. We wish, in concluding our remarks on lingering labor, to renew the cautions already expressed relative to rupturing the membranes. We have said that, to allow the membranes to be ruptured by the natural efforts is the rule; their artificial rupture the exception. We may now add, that the progress of labor may be sometimes accelerated by this procedure—

If the os uteri is fully dilated;

If the head, or a large portion of it, has fairly descended into the cavity of the pelvis; and

If the perinæum is thin and dilatable.

251.* The premature evacuation of the waters, occurring either spontaneously, or from the effort of the accoucheur, renders the woman extremely uncomfortable, as they may continue dribbling away for some days, attended by occasional harassing but unprofitable pains, the patient being kept in constant anxiety about the coming on of parturition. It is worthy of observation that laboı seldom occurs, in these cases, till the whole of the liquor amnii has passed off; but, when the contractile efforts of the uterus do supervene, the process is generally quickly terminated, and quite as safely as in other cases.

252. The funis may pass down with the waters, and descend below the head, and the protraction of the labor, which it was intended to avoid by the artificial rupture of the membranes, is frequently produced thereby, as the comparatively hard and unaccommodating head of the child is substituted for the soft and elastic bag containing the waters, in the process of dilating the os uteri and upper part of the vagina.

253. It is, therefore, very evident that the interruption of the natural progress of delivery, and the injudicious management of the attendant, may convert that which was natural into lingering, and perhaps difficult labor.

254. The indiscriminate exhibition of cordials, the inactivity of the woman herself, and the excitement of friends, is prejudicial. We must dissuade her from bearing down or forcing the pain, as it is termed, till the parts are prepared for the expulsion of the child; we must not irritate and inflame the parts by too frequent examinations; and we must not allow the bladder to become unduly distended.

Chapman, in his fortieth case, gives an account of a poor woman who died undelivered, in consequence of an over-distended bladder

Class I. Order 3.—*Twin labor*

Anomalous Labor, order 3:—Denman. Preternatural Labor, order 7:—Burns. Distokia Gemina:—Merriman. Plural Birth:—Aitken.

255. As it is universally allowed that no infallible criterion exists by which we can discover a plurality of children in utero before their birth, so it is a matter of congratulation that in their delivery we need not greatly deviate from those rules which govern the labors of single children. No difference of opinion can exist as to the birth of the first child; if it present naturally, it will of course be managed as a natural labor; if preternaturally it will require treatment suited to its individual case. It does sometimes happen that a part of the second child is combined with the presentation of the first, and thus the case is rendered clear, before the completion of the first birth. After this it is proper in every case, previously to any attempts for the extraction of the placenta, and more especially where we suspect a plurality of children, carefully to examine the abdomen, and, if we are not satisfied by such an examination, to pass two fingers to the os uteri, when we can scarcely fail to discover the precise case. Practitioners of midwifery have differed in several points relative to the birth of the second child, as to whether it should be entirely committed to the natural powers, or, if assistance be necessary, at what time it shall be afforded. These questions may be satisfactorily answered by an observance of facts, and the simplest deductions therefrom.

256. Obstetric science admits of great certainty in its practical details; occurrences of a general or of a peculiar kind may arise, and they may be met by general or peculiar laws; still, however, much must depend on the judgment of the accoucheur in individual cases. If the birth of the first child has been preternatural, or if it has required instrumental aid; if it has been succeeded by hæmorrhage, or complicated with convulsions; we see every reason why the expulsion of the second child should be accomplished with as little delay as possible; and if the converse of this statement were true as to the first child, and if the second presentation were natural, we should not hesitate, after recruiting the patient's strength, to rupture the membranes, the parts having been already dilated by the passage of the first child; and, if the presentation of the second child were preternatural, we should with equal solicitude make the earliest attempt to bring it into the world.

257. When both the children present naturally, and the labor of the first terminates without artificial assistance, we may properly wait for the occurrence of the next pains; if these, however, are deferred beyond an hour, we rupture the second set of membranes, provided the patient be sufficiently recovered from the first labor, and the second birth is seldom protracted, as all the softer parts have been previously dilated.

258. We have found great advantage from the application of the abdominal bandage immediately after the first birth, as, by gentle pressure of the uterine parietes, we induce a speedier return of the contractile efforts and more effectually prevent any subsequent flooding. A very singular case of complicated labor, from locking of the heads of twins, is related by Mr. Allan in the second part of the twelfth volume of the Medico-Chirurgical Transactions. Dr. Clough also published a curious instance of twins in the Medical and Physical Journal, both of which were discovered by the midwife, one presenting with the feet, and the other with the head. The labor advanced very slowly, on which account Dr. Clough

was called in. He found the feet and body of one child, with the arms down on each side, protruded through the external orifice, and assisted to extract the shoulders. Still finding a difficulty he examined again, and ascertained that the head of the second child and that of the first were in the pelvis together. By the efforts of the uterus, the head of the second child was expelled, and then that of the first: both had been long dead; the mother recovered. A greater number of twin than of single children die during infancy, and of quadruplets very few reach maturity.

The following statements and observations are extracted from appendix, No. 20, to Dr. Merriman's Synopsis of Difficult Parturition.

259. 'There seems to be a very extraordinary variety in the averages of twin and triplet births in different countries, and under different circumstances. Thus the average of twin births has been stated,

By Dr. Clarke, at the Dublin lying-in-hospital, as	1 in 56½
By Dr. Bland, at the Westminster Dispensary, ...	1 in 80
By professor Boer, in the Vienna lying-in-hospital, ...	1 in 80
By Dr. Denman, at the British hospital, ...	1 in 91
By Dr. Denman, at the Middlesex hospital, ...	1 in 93
By Mr. Burns in his own practice .	1 in 95
By Madame Boioin, at the Hospice de la Matenrité, ...	1 in 132
By Mons. Tenon, surgeon to the Salpêtrière Paris, ...	1 in 96

'Respecting triplets the averages are still more various: many accoucheurs, of very extensive practice, have passed through a long life without once witnessing three children at a birth.

260. 'Dr. Bland kept a very exact register of 1897 women delivered at the expense of the Westminster General Dispensary, among whom there was one case of triplets; while I held the office of physician accoucheur to that charity, about 3500 women were delivered, among whom I was twice called to triplet labors.'

261. In the first 18,300 women delivered at the British lying-in-hospital not a single instance of triplets had occurred; but there were three such cases among 20,357 women delivered at the Hospice de la Maternité, at Paris, and nineteen among 59,354 women at the Dublin lying-in-hospital, or one in 3124. The averages of four children at a birth can scarcely be ascertained, yet several such instances are known to have happened; and there are a few authentic histories of five at a birth. Dr. Osborn is said to have once witnessed an expulsion of six abortive ova; and Borellus asserts that, about three years before he published his second Century of Observations, the wife of a nobleman in Languedoc was delivered of eight at a birth. Borellus, it must be acknowledged, tells many other marvellous stories. Haller says upon the subject 'Non raró fœmina geminos fœtus parit; rarius paulo tres, neque unquam supra quinque.' *Physiologia*, 929.

Class II.—Difficult Labor.

Definition.—See page 547.

Order 1.—Labors requiring manual assistance; when the nates, the superior and the inferior extremities present.

262. In this order of labors the early knowledge of the presentation is of great importance, and we are not aware of any other method by which it can be ascertained than by examination per vaginam. If, when the finger is at the os uteri, we cannot feel any part of the child, we presume there is something unusual in the presentation, and this opinion is strengthened, when during pain the membranes are thrust down into the vagina in the shape of a cone, there being still no distinct presentation. Under these circumstances a patient requires great attention from her accoucheur, as much of the facility of delivery will depend on the period when assistance is afforded.

263. The os uteri being deprived, except in the case of the presentation of the nates, of early dilatation, the first stage of preternatural labor will generally require a long time for its completion. It is evident that, in this order of labor, presentations of the arm alone, or perhaps when complicated with some other parts of the child, absolutely require turning. Presentations of the breech, and of any part of the inferior extremities, will pass through the pelvis, demanding little if any more assistance than some of the presentations of the head: indeed we are inclined to believe, with the exception of the greater risk to the child, that face cases are more difficult and painful than presentations of the breech. The operation of turning, the first great improvement in obstetric science, is one oftentimes of considerable difficulty, and always of some degree of risk. The precise time and circumstances under which it is to be attempted have excited much controversy, although the opinions of practitioners are now pretty unanimous on certain important points.

264. Where the os uteri is undilated, and the genital organs rigid, turning ought never to be attempted. Where however the os uteri is dilated, even if the vagina and the perinæum are only beginning to expand, turning may be attempted; as, under any circumstances, the vagina and the parts about the outlet cannot receive their full dilatation till the nates are making pressure upon them. Supposing the os uteri to be expanded, to the size of a dollar, turning with great care may if necessary be commenced. If the membranes are ruptured, and the liquor amnii has escaped, the contractile efforts of the uterus are more powerful, and, from its closer approximation about every part of the child, the difficulties of the operation are much increased. Our own practice, in these cases, is to make out as early as possible the presenting part, and, if the pains are at all powerful and frequent, not again to leave the patient, so that we may seize

the most favorable opportunity for the introduction of the hand. If the os uteri is not dilated, of course, we wait; and, if it continue rigid, we employ the means already prescribed to induce a contrary state. If, however, the mouth of the uterus is sufficiently expanded, and the other genital parts are at all in a favorable condition, proceed to the delivery, much preferring that the waters shall not have passed off.

265. For the following observations on spontaneous evolution, and the exvisceration of the fœtus, the author of this paper is indebted to his friend Dr. Francis Ramsbotham.

266. Since the time when Ambrose Parey adopted the comparatively safe and easy operation of turning the child, and delivering by the feet in arm and shoulder presentations, the superiority of that mode of terminating the labor over others previously followed has been so generally acknowledged that it may be said to have become a universal practice. Few men in the present day will rely on the unassisted powers of nature for accomplishing the patient's release, and fewer still will attempt the dangerous and often impracticable expedient of returning the shoulder into the uterus and bringing the head to the pelvic brim.

267. Although the merit of having first suggested this improvement in practical midwifery be not conceded to Parey, still it must be allowed that he is entitled to our warmest praise for having by his recommendation made it generally known, and by his personal example proved its safety and its efficacy. So evident indeed are the advantages of Parey's operation that its revival and adoption may be considered almost an era in the history of midwifery.

268. It is not denied, however, that in some cases of shoulder presentation, the labor has been concluded by the natural efforts alone, unaided by manual interference. Dr. Denman was well aware of this fact, and has described the case as being a 'spontaneous evolution.' This talented and observant practitioner considered that a true evolution actually took place; he thought that the fœtus was too large to pass through the pelvis doubled; that the breech, being acted on by the continued uterine contractions, was gradually forced lower into the pelvis; and that at the same time the shoulder retreated into the womb, occupying the space which had been evacuated by the breech.

269. Dr. Denman's explanation was considered perfectly correct, and generally received by the profession, until Dr. Douglas of Dublin, in a pamphlet first published in 1811, proved that the description was inaccurate; he observes that it is incompatible with the received ideas of uterine action to suppose that the uterus, when contracting so powerfully as to force down that part of the child which was at its fundus, could at the same moment form a vacuum into which another portion already low down in the pelvis should recede.' The uterus indeed embraces and closely surrounds the fœtal body; the shoulder cannot recede either into the uterine or vaginal cavities, since the space evacuated by the breech no longer remains, but is destroyed by the continued uterine contractions.

270. To Dr. Douglas, therefore, we are indebted for a true history of the process. He has clearly demonstrated that the fœtus does pass the pelvis in a doubled position, describing a partial evolution indeed, and turning on the lowest point of the symphysis pubis as its centre.

271. He has given to the profession the following observations. 'In all the cases related by various practitioners, on the subject of the evolution, it is acknowledged that shortly before its occurrence the shoulder of the child had been forced very low into the pelvis; and that the thorax had occupied so much of its cavity as to preclude the practicability of the hand of the accoucheur being passed up into the uterus for the purpose of turning, as is usually done in such presentations. The shoulder and thorax, thus low and impacted, instead of receding into the uterus, are at each successive pain forced still lower, until the ribs of that side corresponding with the protruded arm press on the perinæum. At this period not only the entire arm, but the shoulder also can be perceived externally, with the clavicle lying under the arch of the pelvis. By further uterine contractions the ribs are forced more forward, appearing at the os externum, as the vertex would in a natural labor, the clavicle having been by degrees forced round on the anterior part of the pubes with the acromion looking towards the mons veneris.' The body of the fœtus then is bent into a curve; the head rests above the pubes internally; the clavicle presses against the lowest point of the symphysis pubis partly externally; the arm and shoulder are entirely protruded; the acromion is turned up towards the mons veneris; and a part of the side of the thorax closes the genital fissure. The abdomen and loins at the same time occupy the lower part of the pelvis, and the breech has either entered the pelvic cavity or lies at the brim ready to descend into it. By a continuance of uterine action the breech is expelled, sweeping the hollow of the sacrum, and distending the perinæum to a vast extent. It will be evident that, during this expulsion of the fœtus in this doubled form, the perinæum must be placed much more on the stretch than happens in a natural labor or a case of original breech presentation.

272. The spontaneous evolution is not to be expected where there exists a contracted pelvis; it can only take place when that cavity bears a large proportion to the size of the fœtus, and is most likely to happen under premature labor. From the pressure which the fœtal body must necessarily suffer it is not likely that the child will be born with life. Some cases, however, noticed by Dr. Denman sufficiently prove that the compression is not necessarily fatal to the infant. The longer the time occupied in the completion of the evolution, the more powerful the uterine exertions which are required to perfect it, and the smaller the mother's pelvis, the less probability will there be of the child's being preserved.

273. The knowledge that the delivery may possibly take place under the circumstances detailed above must be considered a great point gained in practical midwifery, since, in a few of those cases where the attendant is unable to in-

troduce his hand into the uterus in consequence of its firm contraction, he may trust with safety to the natural powers; especially if together with a small or premature fœtus there be a large pelvic cavity, strong uterine action, and an apparent disposition in the child to pass doubled. But, should these fortunate occurrences be wanting, he may have recourse to another mode much less likely to injure the mother than the forcible passage of the hand into the uterus under a state of strong and permanent contraction; namely, that of lessening the bulk of the fœtus, by taking away the viscera of the chest and abdomen, and afterwards imitating the 'spontaneous evolution,' or in other words extracting the body in a collapsed state.

274. Let it not be supposed that we should recommend this operation to supersede the common practice of turning under ordinary cases of shoulder presentation, but that it should only be resorted to by the practitioner in those rare instances when being called upon to deliver, perhaps many hours after the rupture of the membranes, he finds any continued attempts at turning would be attended with the danger of uterine laceration.

275. The operation is in itself easily performed; and the appalling feeling which every man must experience on perforating the head of a fœtus while ignorant of its life or death here can have no place; because the pressure on the child's body must have deprived it of vitality before the operation can have become necessary. The powerful objections, therefore, which obtain against the use of the perforator in general are not applicable in these cases.

276. No other instruments will be found necessary than the perforating scissors and the crotchet; the scissors are much preferable to the perforators in common use, as they possess a cutting edge both externally and within; with them, therefore, the separation of the viscera from their attachment is more easily effected.

277. The woman having been placed on her left side, the position most suitable for the performance of all obstetrical operations, as large an aperture as possible must be made into the chest at the most convenient part, by the division of one or more ribs; and through this opening the heart and lungs must be extracted, the diaphragm must then be perforated, and the liver may be easily removed; the intestines also may be drawn out without difficulty. The bulk of the fœtus being thus reduced, the body will collapse; and, if the uterine efforts continue, the evolution as described above will most probably speedily occur. Should the pains, however, have ceased, and the breech not descend after the removal of the viscera, the crotchet may be introduced through the aperture, and fixed within on some point of the fœtal pelvis; sufficient force may then be applied to extract, and the breech will be protruded, sweeping the sacrum and perinæum.

278. This operation Dr. Francis Ramsbotham thought it right to perform three times, and he has been present on two other occasions when it was had recourse to; nor has he found any particular difficulty attending it.

279. The separation of the head from the body at the neck is another mode by which delivery may be effected in cases of shoulder presentation, when the contracted state of uterus prevents the child being turned. In the case requiring this, as well as the preceding operation, the death of the child must have already taken place, and the objections against it are the difficulty of its performance, and the unsuitableness of the instruments which have until lately been proposed for the purpose. The scissors invented by the late Dr. Coombe have not been found to answer. The best instrument with which I am acquainted is a cutting hook made some years since by Dr. Ramsbotham Senior, of which a correct representation is given in Dr. D. Davis's excellent work on Instrumental Midwifery. This instrument possesses the curve of a large sized blunt hook; its cutting edge extends throughout the inner side of the whole curve to within half an inch of the extremity; and it is intended to be introduced over the neck, being carefully directed by the finger. When applied it is to be used as a saw, and by a gradual pressure downwards, the vertebræ and soft parts are divided.

280. On the separation of the head being effected, the body may be extracted by means of one or other of the arms, and should the pains have subsided the head may afterwards be extracted by a blunt hook or crotchet introduced either into the foramen magnum or the mouth. The possibility of any injury being inflicted on the soft parts of the mother may be prevented by the index finger of the left hand being kept against the blunt extremity of the instrument during its action.

281. Should the pelvis be filled by the fœtal chest, or abdomen, exvisceration will be most expedient; if, on the contrary, the neck originally presented over the centre of the brim, which must very rarely occur, the best mode of proceeding will be to decapitate the child. In one instance, in consequence of the narrowness of the pelvis, even after the child had been completely exviscerated, the body would not pass; we were therefore obliged to separate the head before extraction could be effected.

282. *Of the presentation of the nates.*—Many causes have been assigned for transverse or cross labors, such as the obliquity of the uterus, the shortness or the circumvolutions of the funis round the body of the child, and shocks affecting the mother during pregnancy. It is, however, very doubtful whether any of these circumstances influence the precise situation of the fœtus, as we have frequently met with every one of these occurrences, and still the head has been the presenting part. We are more disposed to attribute them to some peculiarity in the manner of descent of the ovum into the womb, or to some disproportion existing in the earliest months between its various parts.

283. An early examination will generally enable us to discover the presentation before the rupture of the membranes, and when the superior extremities lie over the centre of the pelvis, this is of no small importance. The breech may be distinguished by the pulpy softness of its feel, by the cleft between the buttocks, by the parts of generation, and sometimes by the dis-

charge of the meconium with the liquor amnii. The head, and more especially the face, is sometimes confounded with the breech. The roundness and hardness of the head, together with its sutures and fontanelles, and the inequalities of the face, will enable us to form a correct diagnosis between the two parts.

284. Labors, where the head of the child did not present, were as we have already seen in the history of obstetric science, much dreaded; and till a very much later period than the time of Celsus, thrusting up the part, and endeavouring to bring down the head, was the common practice. Celsus gives the following recommendation:—'Et si clunes os uteri urgere cæperunt, iterum retro repellendæ sunt, conquisitusque. pes ejus adducendus.' Portal, who practised with great celebrity in Paris, about 1668, entertained correct notions and gave very judicious directions for the management of presentations of the feet and nates. He says (chap. iv. p. 211), 'If the feet of the child come foremost, search the inward orifice of the womb, which if you find thick and not open as yet, you must not be too hasty, nor hazard any violent delivery of the child, but stay till the womb is sufficiently open to afford a passage for the birth. When the buttocks come foremost you must not be impatient; for, though the labor proceeds very slowly, yet it is not much more difficult than a natural birth: whence it is that our midwives say, by way of proverb, that where the buttocks can pass the head will follow of course. The position of the child in this case is doubled, with the thighs upon the belly; and the passage being once opened for the buttocks, by the reiterated pains, the head follows without much trouble; you must take hold of the feet as soon as they come out, and afterwards the head and shoulders.'

285. The erroneous and generally fatal practice, as to the child, of pushing up the nates, still continued: so difficult is it to shake off prejudices handed down from antiquity. Smellie was evidently doubtful both of the natural powers and of the standard capacity of the pelvis; in relation to breech cases we find him giving directions about stretching the external parts, dilating the os uteri, pulling down the legs, and raising and pushing up the nates. Dr. Hunter says, 'When I first began practice, I followed the old doctrines in breech presentations, although I did not like them, but yet dared not broach new ones till I got myself a little settled in life; at this time I lost the child in almost all the breech cases, but since I have left these cases to nature I always succeed.'

286. There is now no difference of opinion as to the propriety of leaving these cases to the natural efforts; for although the nates do not accomodate themselves so completely to the shape of the pelvis, yet they do not require so much room as the head; and if the labor, especially in its first stage, be allowed to proceed uninterruptedly, the nates will ultimately be protruded through the external parts; when the case must be managed as a footling presentation. We have seen many presentations of the nates; and although the protracted birth of the head, even when every measure had been employed to facilitate its expulsion, has rendered us less successful in the preservation of the child's life than Dr. Hunter, we are quite convinced that the preservation of the child will greatly depend on our little interference in the early part of the process.

287. *Of presentations of the inferior extremities.*—These have generally been regarded as the simplest and probably the safest of all the preternatural presentations, so far as regards the mother. The child, however, is in jeopardy, more particularly if it be a first labor, and the mother be rather advanced in life, and of rigid fibre. The foot may be distinguished from the hand, by the weight and resistance it gives to the touch, by the shortness and evenness of the toes, except the prominent great toe, and by the projection of the heel.

288. The early delivery of the head in these presentations is of vast importance, as, between it and the pelvis, the umbilical cord may suffer fatal compression. We are not to hasten the delivery of the child's body under the presumption that, by so doing, we diminish the risk of pressure on the cord; for on the contrary its slow passage dilates the parts of the mother, and affords greater space for the passage of the head, The rule therefore is, not to interfere till the nates are born; not to rupture the membranes; and supposing we are not called till the waters are evacuated, and the feet in the vagina, not even then by pulling them down to anticipate the effects of the natural pains. If, when the umbilicus passes beyond the os uteri, the funis descends further, a portion of it should be drawn out of the uterine cavity, that it may be stretched and compressed as little as possible when the head emerges from under the pubis.

289. If the nates are fairly in the world, the period to render assistance has arrived; and the rules for its bestowment are equally applicable to breech as to footling cases. A warm napkin, or flannel, is to be wrapped round the lower extremities of the child, and by swaying it a little backwards and forwards, or from side to side, its descent is facilitated. We have already explained the importance of the turn which the head makes in descending from the brim into the cavity of the pelvis in natural labor. In presentations of the breech and feet this turn is equally desirable; and if, when the nates have reached the external parts, we find the toes pointing towards the symphysis pubis, we know the head is unfavorably situated. Grasping the parts firmly, having previously covered them with a napkin, we wait for the next pain, and then we give such an inclination to the body of the child as shall direct its abdomen towards its mother's spine. Some practitioners have thought the arms ought not to be brought down, alleging that, while extended by the sides of the head, they prevent the os uteri from contracting round the neck of the child, and that by extracting them we endanger their dislocation or fracture. In these opinions we do not concur; for, if the early part of the labor has been deliberately conducted, the os uteri will generally be too fully dilated to allow of its contraction round either the neck or

the upper part of the child's head. It may so happen, if the pelvis be large and the head small, that the arms and cranium of the fœtus may with difficulty be brought away together; but as thus situated they occupy much room, producing delay and a compression of the softer parts, we prefer the previous extrication of the upper extremities. When, therefore, the axillæ of the child are on a level with the external genitals of the mother, the body of the fœtus must be placed completely out of the way, and two or more fingers may be passed to the bend of the elbow, when the arm may generally, with some little management, be brought down over the face. Having accomplished the birth of one arm, there is seldom much difficulty in getting away the other, and thus the passage of the head is facilitated. If, however, there are any obstacles to the birth of the cranium, and the uterine efforts alone are seldom sufficient for its expulsion, it is important that assistance should be speedily afforded, as compression on the cord will quickly destroy the life of the child.

290. For this purpose, we pass two or three fingers of the right hand over the nape of the neck, and insinuate a finger of the left hand into the child's mouth; by these means we depress the chin, alter the position of the head, and better adapt it to the pelvis; and, by a moderate extracting force, we bring forward the head, taking care lest by violence we injure the fœtus.

291. In cases of extreme difficulty the blunt hook is required; or a silk handkerchief passed over the bend of each thigh, giving us a complete command of the parts, may be employed; by either of these means we may, co-operating with the pains, draw down the nates to the outlet. We were lately called to a breech case by one of Dr. Blundell's pupils, in the management of which we had extreme difficulty. The woman was forty years of age, having a pelvis greatly deformed in its antro-posterior diameter. The waters had been evacuated many hours—the os uteri was fully dilated—the womb was contracting powerfully—and the breech might perhaps be considered as having just entered the cavity of the pelvis. She had three times previously been delivered by instruments. Hoping, however, that, as the breech occupies less space than the head, as she was a strong woman, and as no unpleasant symptoms had occurred, the breech might be thrust into the world by the natural efforts, we determined to give a few more hours for their full exertion. The bladder was emptied by the catheter, and the rectum was unloaded by a clyster. Six hours elapsed without any further advance of the presenting part, and we determined to use the blunt hook. Having fixed it successively in the fold of each thigh; and, having drawn down with the greatest caution for upwards of three quarters of an hour, very little progress had been made; nor was it till the point of the instrument was hitched over the sacro-iliac symhondroses that we could extract the breech. It ought to be stated that during the process there were intervals of rest, and the efforts at extraction were temporarily intermitted when the pulse was getting above 120 or 130: the child had been dead some days.

293. *Of presentations of the superior extremities.*—There are no cases in obstetric practice requiring a union of firmness and skill in a higher degree than presentations of the superior extremities. If they are discovered early, and their treatment be commenced under the most favorable circumstances, great tact and delicacy are necessary to avoid injury to the uterus and softer parts. And whether the hands, the elbow, or the shoulders present, they cannot pass through the pelvis without some alteration in their position. We have already noticed, as an era in obstetric science, the partial approximation to the present plan of treatment in the turning of a dead child by Celsus, although the principal merit of its revival and complete establishment, as an invariable rule, must be given to Ambrose Paré; who enjoins in all these presentations to turn the child and to bring it into the world by the feet; Dr. W. Hunter, believing that the parts would be much more dilated for the subsequent passage of the head if the breech was brought away first, instead of the feet, recommended to his pupils 'to introduce their hands into the uterus and gently to put up the arm and to turn the child to a breech presentation. Reduce it, if possible, to a perfect breech case, that it may come more gradually, on account of the head and navel string, lest you strangle the child. If, however, you find this impracticable, let it come footling, but sustain the child at the hips as long as you can, they being, next to the head, the largest and most unyielding part.'

294. If perfect agreement exist as to the way in which this operation is to be performed, there is great diversity of opinion as to the precise time when it shall be undertaken. Supposing we find the arm protruding through the os uteri, the membranes unbroken, and the os uteri fully dilated, there need be no hesitation. The arm of the operator is to be bared and smeared with some unctuous substance; and having, if they require it, gently dilated the external parts, the hand may be slowly carried to the os uteri, taking care to insinuate it through this part during the absence of pain. The membranes are now to be ruptured, and the hand will come in immediate contact with some part of the child. Having reached the feet, the operator must be careful so to draw down as that the abdomen of the child shall be placed towards the mother's spine. Continuing the extraction, the presenting arm will be gradually drawn into the uterus; and when the feet have cleared the external parts it becomes precisely similar to a presentation of the feet; and the rules already prescribed are applicable to its management.

295. Where the waters have been long evacuated before the practitioner sees his patient, the os uteri not fully dilated, and the pains vehement and quick, turning must not be attempted. We are aware that some practitioners do not concur in this opinion, urging that the uterus will most probably be ruptured by the continuance of the pains, the child remaining in this untoward position. The danger of rupture from delay, in this case, cannot exceed the risk of laceration, were the hand, for the purpose of turning, to be introduced into a uterus so powerfully contracting. In these cases, and we have seen

several, we bleed the patient if at all plethoric, to fourteen or twenty ounces, and follow up the abstraction, by sixty or eighty drops of the tinct. opii; by these means the uterine action will most probably be much diminished, and then the turning may be safely attempted. It may be urged that, although the uterus be not ruptured, yet the continuance of the pain will force the arm, the shoulder, or perhaps the head of the child so firmly into the uterus as to render it impossible to turn, even when its inordinate action has ceased. We are quite alive to the difficulty and risk which attends this jamming of the fœtus into the pelvis; but we think it less than what would accrue from thrusting the hand into this viscus when rigid, powerfully contracting, and irritable. The first case of turning we saw was one in which attempts had been made during the contractile efforts, to rectify the position of the child. Opium alone had been given, without any previous abstraction of blood. Three attempts proved unsuccessful, and eighty drops of laudanum were exhibited, the woman being undisturbed for two hours; after this period the child was extracted with ease, but the uterus had ruptured, and she died a few hours after delivery. The hands may be distinguished by their flatness, thickness, and breadth, by the length and inequality of the fingers, by the shortness of the thumb, and by the thumb bending into the palm of the hand.

Class II. Order 2.

296. Labors which cannot be completed without the aid of extracting instruments, of which some are designed to save the lives both of the mother and the child, while others are intended to preserve the life of the mother at the expense of the life of the child.

297. We have already considered lingering labor as dependent on one of two causes, either on diminished power, or increased resistance; and, when either of these exist to so great an extent as seriously to retard the progress of parturition, the skill, the promptitude, and the experience of the accoucheur are immediately in exercise. If after a fair trial of every expedient which the peculiar circumstances of the case may suggest, and after having allowed the fullest exertion of the natural powers compatible with the safety of the woman, the labor makes no advance, we must have recourse to instrumental aid. It is true that this necessity seldom arises; and we believe when the early stages of labor are well understood, where there is no undue interference, either from timidity or haste, the cases requiring the use of extracting instruments will be few indeed. Yet labors are occasionally occurring which cannot be terminated by the natural powers, where, from the disproportion between the pelvis and the head of the child, or from some deficiency in the expulsatory power, from the passions of the mind, or the diseases to which the human species are incident, the performance of duties is required from the practitioner, which he is solely enabled to discharge, because he has made midwifery a study, and is intimately acquainted, not only with natural but difficult parturition. These are the cases which distinguish the judicious accoucheur from the man who thinks that midwifery is undeviatingly simple and easy, and who at length discovers that he has neglected to acquire that knowledge without which the safety of his patients, and his own character, will soon be compromised. It is here that officious interference, neglect in the early stages manually to remedy a mal-position, the exhibition of stimulants under a mistaken idea that they impart strength, with many other errors equally pernicious, render that labor difficult and instrumental which, under other treatment, might have been concluded by the exertion of the natural powers.

298. Writers have been accustomed to enumerate a variety of appearances, which they have considered as presumptive signs of difficult labor; but the least reflection must convince us that as women of every form, of every complexion, and of the most diversified mental and physical powers and dispositions, have both natural and difficult labors, the knowledge of these supposed indications cannot be of any great importance in actual practice. A necessity for artificial aid is principally arising, first, from an excessive degree of those symptoms which have been already described under lingering labor; and which, from their continuance, induce such a powerless state of system as to call for the employment of instruments, intended to preserve the lives both of the mother and child; and, secondly, from distortion of the pelvis existing in every degree, from the slightest intrenchment on its capacity to absolute deformity, creating of itself a disproportion between the relative size of the fœtal head and the canal through which it must pass. It is needless to remark that these cases frequently demand the use of the perforator.

299. In the first kind of parturition the pains become weak, short, and inefficient, producing no effect on the head of the child; sometimes they are entirely suspended; and although their cessation within the first twenty-four hours does not justify the use of instruments, as it may be only temporary, yet if it occur at the end of the second or third day, if the pulse, the countenance, and the general appearance of the woman are expressive of extreme debility and fatigue, a strong presumption is afforded of the inability of the natural powers to complete the delivery without the assistance of art. If, in addition to these symptoms, we have shivering and vomiting, a pulse of 120 or 130, furred tongue, a hot dry skin, great thirst, restlessness, heat and soreness in the vagina and os uteri, we may feel assured our patient has approached to a state from the evil consequences of which instrumental aid will alone deliver her. The forceps will now be required; and, before we pass on to the next variety of labor, we shall describe the manner of its application, first enjoining a few preliminary measures. The forceps is an instrument intended to lay hold of the head of the child in difficult labor, and to extract it as it presents; and, as now improved, in the hands o a prudent and cautious operator, it may be employed without doing the least injury either to mother or child.

300. The bladder and rectum should be pre-

viously evacuated, not only to enlarge as much as possible the capacity of the pelvis, but to prevent the risk of injury to these parts themselves.

301. The first stage of labor must be completed, and the os uteri and perinæum in a dilatable and yielding condition, ere we think of employing instruments. It is a rule in the use of the forceps to be entirely guided by the circumstances of the mother, or rather no attempt must be made to save the life of the child when the mother may thereby be placed in jeopardy. The assistance given by instruments should co-operate with the contractile efforts of the uterus; and, if the pains have entirely ceased, intervals of rest must be observed; and it will be attended with advantage to watch the pulse, and to pause when it is exceeding 125 or 130.

302. The extracting efforts should always be made in the direction of the axis of the pelvis; so if we are employing the long forceps, and the head is above the brim, we should draw down in a line towards the coccyx; but, when the head is approaching the outlet, the direction of the extracting force must be forwards, or towards the pubes. The time occupied in instrumental deliveries greatly varies; for, while some may be safely terminated in a very short time, others require perhaps an hour for their completion. The usual obstetric position will do sufficiently well for instrumental purposes; the nates should be brought close to the edge of the bed, and the knees should be drawn up at right angles with the abdomen. When we can feel the ear in a vaginal examination, the case is manageable by the forceps; as its blades, being twice the length of the finger, will embrace the head. Dr. Denman, whose invaluable aphorisms on this subject ought to be consulted by every obstetric practitioner, says, the difficulties which attend the application and use of the forceps are far less than those of deciding upon the proper time when, and the cases in which, it ought to be applied. We may subjoin to this remark that, except where syncope is occurring from hæmorrhage, the ear may have remained in this situation some hours before the forceps is absolutely required.

303. The instruments now in use are:—

1st. Those intended to save the life both of the mother and the child; they consist of the

Short forceps,
Long forceps,
Vectis, and
Blunt hook.

2d. Those in the use of which the life of the child is sacrificed to the safety of the mother; they are the

Perforator,
Craniotomy forceps,
Crotchet, and
Scalpel.

Cases of the powerless labor such as we have already described, presentations of the vertex, and of the face, forehead, and ear, are all manageable by the forceps or lever, if circumstances do not exist rendering the employment of the perforator necessary.

304. There is no occasion, says Dr. Denman, and it would be hurtful to attempt, to change the position of the head when the forceps is applied, before we begin to extract. For, if the action with the forceps be slow, the head of the child will turn in the same manner, and for the same reasons, as in a natural labor. Therefore the forceps, being fixed upon the head, must also change its position according to its descent, and the handles be gradually turned from the ossa pubis and sacrum, where they were first placed, to the sides of the pelvis. The handles of the forceps likewise, though originally placed far back towards the sacrum, that is, in the direction of the cavity of the pelvis, will be gradually turned, as the child advances, more and more towards the pubes, that is, in the direction of the vagina. The first action with the forceps must be to bring the handles, firmly grasped in one or both hands, slowly towards the pubes, till they come to a full rest. After waiting till the pains return, or an imaginary interval if there should be a total want of pain, the handles are to be carried back in the same slow and cautious manner till the lock reaches the perinæum, using at the same time a certain degree of extracting force. The subsequent actions must be from handle to handle, or occasionally by simple attraction; but the action of that blade which was towards the pubes must be stronger and more extensive throughout the operation than the action with the other blade, which has no fulcrum to support it. By a repetition of these actions, always directed according to the position of the handles, with their force increased, diminished, or continued, according to the exigence of the case, we shall, in a short time, perceive the head of the child descending. When the head begins to descend the force of the action with the forceps must be abated; and, as that advances, the direction of the handles must change by degrees more and more to each side and towards the pubes. The lower the head of the child descends the more gently we must proceed, in order to prevent any injury or laceration of the perinæum or external parts, which are likewise to be supported in the same manner as in a natural labor. In some cases the mere excitement occasioned by the application of the forceps, or the very expectation of its being applied, will bring on a return or an increase of the pains sufficient to expel the child without its assistance. In other cases we are obliged to exert very considerable force, and to continue it for a long time; so that one operation may be safely and easily finished in twenty minutes, or even a less time, and another may require more than an hour for its completion, and the repeated exertions of very considerable force. In some cases it happens also that the obstacles to the delivery exist at one particular part of the pelvis, and, when that is surmounted, the remainder of the operation is easy; but in other cases there is some difficulty through the whole course of the pelvis. Before the exertion of much force we are always to be convinced that a small or a moderate degree of force is not equal to our purpose. In every case in which the forceps has been applied it are not to be moved before the head is extracted, even though we might

have little or no occasion for it. When the head of the child is born the forceps is to be removed, and the remaining circumstances are to be managed as if the labor had been natural.

305. *Of the vectis.*—We have not space, in an elementary treatise like the present, to enter at large into the enquiry of which is the better instrument the forceps or the lever; we know that men well qualified to form an opinion have embraced different views of this question, arising probably from their individual skill in their employment. It must we think be allowed that the lever is a very powerful instrument, and if the soft parts of the woman be constituted its fulcrum, its use will be highly dangerous; notwithstanding it may be applied to any part of the head, and may be used earlier than the forceps, we think the forceps by far the better instrument.

Class II. Order 2.

306. We shall now detail a few particulars relative to those difficult cases of parturition, which, from the size of the head, or from distortion in the pelvis, can neither be protruded by the force of the natural pains, nor extracted by the forceps; and which consequently require the life of the child to be sacrificed for the safety of the mother. This operation was, by the ancients, called embryotomy. 'The reluctance,' says Dr. Merriman, 'which every well regulated mind must feel at employing the perforator, even in cases of the greatest necessity, while the infant is yet living, naturally occasions a wish to delay the operation, till there are some indications of the child's death; and these indications are sought for in certain symptoms which most writers on midwifery have been careful to enumerate. These symptoms are, a want of fœtal motion and pulsation at the fontanels; a rolling, as of a lump or dead weight, to that side on which its mother is lying; shivering fits on the part of its mother, flaccidity of the breasts; fœtor of the uterine discharges; and an emphysematous and very loose feel of the bones of the cranium.

307. When the head, from its extraordinary bulk, is detained at the brim of the pelvis, on evacuating the contents the bones of the cranium immediately collapse, and the head is afterwards propelled by the force of the labor pains. If these are insufficient, the extraction must be made with the craniotomy forceps. The unfavorable position of the head is, of itself, a cause insufficient to justify the use of destructive instruments, which ought never to be employed but in extreme cases, after every milder method has failed. From the difficult access to the cranium, in order to make a perforation and evacuate the brain, a face case makes a very troublesome and dangerous crotchet one; very fortunately in narrow pelves the face rarely presents, and very seldom advances far in that direction, at other times the position may be so altered that the crown, the back of the ear, or some other part of the cranium, can be reached: otherwise, the crotchet must be fixed in the mouth or orbit of the eye, and the head brought along in that direction, till the perforator can be employed to open the skull

308. But the grand cause of difficult labor is the narrowness or distortion of the pelvis. For when at the brim, instead of four inches and a quarter from pubes to sacrum, it measures no more than one and a half, one and a quarter, two, or two and a quarter, the use of instruments becomes absolutely requisite; and very frequently in those of two and a half and three inches; or when the diameters through the cavity, or at the inferior aperture of the pelvis, are retrenched in the same proportion, difficulties will arise, and the delivery, except the labor be premature or the child of a small size, cannot be accomplished without the assistance of destructive instruments.

309. We judge of the form and size of the pelvis by the external make and form of the woman, by the progress of the labor, and by the touch. When the fault is at the inferior aperture the touch is pretty decisive; if a protuberance is felt in the os sacrum, instead of a concavity; if the coccyx is angulated; if the symphysis pubis projects inwards, in form of an acute angle; if the tuberosities of the ischia approach too near each other, or the one tuber be higher than the other; such appearances are infallible marks of a distorted pelvis. But, when the narrowness is confined to the brim, this is only to be discovered by the introduction of the hand within the pelvis. The projection of the lumbar vertebra over the sacrum is a species of narrow pelvis that most frequently occurs in practice. In this case the child's head, by the pressure it sustains between the pubes and sacrum, is moulded into a conical or sugar-loaf form, the parietal bones are squeezed together, overlapping one another, and will be felt to the touch, when the labor is advanced, as an acute ridge. Instead of the complicated instrumental apparatus, invented by the ancients, such as screws, hooks, &c., for fixing in, laying hold of, and extracting, the head as it presented, an operation in many cases difficult and dangerous, when the head was bulky or the pelvis narrow, as the woman frequently lost her life in the attempt; the practice of diminishing the size of the head, by opening the cranium and evacuating the brain previous to the extraction, is a modern improvement, and an important one; the instruments for this purpose consisting of the perforator, a blunt hook, and the craniotomy forceps.

310. When the accoucheur is under the necessity of destroying the child to preserve the mother, she must be laid in the position already advised for the application of the forceps, and the same rules recommended for the one operation will in general apply to the other. Thus in the narrowest pelvis that occurs, previous to opening the cranium, the soft parts should be completely dilated, and the head of the child fixed steadily in the pelvis and advanced as far as possible; for, while the head is high and loose above the brim, the application of instruments is very difficult as well as hazardous.

311. The perforatór must be cautiously introduced into the vagina, directed by the hand of the accoucheur; its points must be carefully guarded till they press against the cranium of the child, which they must be made to perforate

with a bowing kind of motion, till they are pushed on as far as the rests; they must then be opened fully, carefully reshut, half turned, and again widely opened, so as to make a sufficient aperture in the cranium.

312. They must afterwards be pushed beyond the rests, opened diagonally again and again in such a manner as to tear and break to pieces the bones of the cranium; they must then be shut with great care, and withdrawn along the hand in the same cautious manner as they were introduced, lest they should bruise or tear the uterus, vagina, or any other part of the woman. The teguments of the scalp should now be brought over the ragged bones of the cranium, and the woman should be allowed to rest an hour or two, according to her strength and other circumstances; the bones of the cranium will now collapse, and if the woman has much strength remaining, or the pelvis be not much distorted, the head, being thus diminished, will be protruded by the force of natural pains, otherwise it must be extracted by the craniotomy forceps introduced in the same manner, and guarding the point on the opposite side while making the extraction.

Class II. Order 3.

Impracticable labor, or that in which the child, even when as much as possible reduced in size, cannot pass through the pelvis, and where the Cæsarian operation becomes necessary.

Of the Cæsarian Operation.

313. This operation consists in making an incision through the abdominal and uterine parietes, sufficiently large to allow the introduction of the hand, and the extraction of the fœtus and its appendages. We know of only one instance in this country, where the preservation of the mother's life has attended its performance, while on the continent, according to M. Baudeloque, it has been abundantly successful. In England this measure is never contemplated till every other remedy has been tried; and one reason of its little success may perhaps be found in the exhaustion which these previous means may have induced. Of twenty-two cases operated on in these islands, twenty-one of the mothers died; of the children ten were born dead; and of the twelve extracted alive, four survived only a few days. The whole number of lives preserved therefore does not exceed nine.

314. The most astonishing case is that of Alice O'Neil, an Irishwoman, operated on by Mary Donally, a bold but ignorant midwife; she made an incision through the abdomen and uterus, with a razor, and held the lips of the womb together with the hand, till some one went a mile, and returned with silk and the common needles which tailors use. With these she joined the lips in the manner of the stitch employed ordinarily for the hare lip, and dressed the wound with white of eggs. The woman recovered in twenty-seven days, and the case is authenticated by Mr. Duncan Stewart, surgeon in Dungannon, and Dr. Gabriel King of Armagh.

315. The cases are very rare indeed which demand this operation; as, when the perforator has been fully employed, children have been delivered, although the distance between the ossa pubis and os sacrum did not exceed one inch and a half, and not more than two inches from one side to the other. There can be no doubt of the propriety of the Cæsarian section, where women near the full time of pregnancy die undelivered, since by this measure the child may be preserved.

316. The danger and the sacrifice of life which invariably attended the use of the perforator, and which frequently followed the Cæsarian operation, induced many enquiries for a plan of treatment which, while it might hold out a fair expectation of safety to the child, should not compromise the welfare of the mother.

317. The section of the symphysis pubis, abstinence on the part of the mother, and the bringing on of premature labor, have been tried for this purpose. Of the first we need only say that it has sunk into complete desuetude, the success attending it not being at all commensurate with the danger incurred.

318. Of the second, proposed by Mr. James Lucas, surgeon to the infirmary at Leeds, in the Memoirs of the Medical Society of London, Signior Assalini relates a case in which it was usefully enjoined; but remarks that no great reliance is to be placed upon it, for women who constantly reject, by vomiting, every particle of food they swallow, have, notwithstanding, on many occasions, large children.

319. Of the third, we believe, most practitioners think highly; and, although it cannot be denied that the mother incurs some degree of danger, it may be affirmed that she is placed in as much, if not more danger, by the use of the perforator.

320. Smellie mentions the case of a woman whose pelvis measured less than two inches and a half of conjugate diameter; she had been five times delivered, and only one child was saved, by being born in the eighth month of a very small size. He has likewise given two plates, showing a pelvis of two inches and a quarter conjugate diameter. One of these demonstrates the impossibility of a full grown fœtus, though the bones of the head are very much compressed, passing immutilated; the other exhibits a seven months fœtus clearing the strait.

321. Dr. Merriman says, that he has been made accurately acquainted with the particulars of thirty-three cases of labor prematurely induced, in the eighth month of pregnancy, on account of extreme distortion of the pelvis. In twenty-one of these the children were born dead; in four, one of which was a case of twins, they were born alive, but incapable of living more than a few hours; nine were born alive, and capable of being reared. Thus nearly one-third of the children were saved, who must have lost their lives had the women gone to their full times, and been delivered by the perforator; and all the women recovered, the majority of whom, if not the whole number, must have been lost, had the Cæsarian section been performed. There are two ways in which premature parturition may be induced, either by the careful puncturing of the membranes within the os

uteri, by the stilette of a catheter or by introducing the finger within the os uteri, to detach the decidua, thus exciting parturient action, by which the membranes may be forced upon, and will dilate the os and cervix uteri, as in natural labor. The management of the subsequent delivery, which generally occurs in from twenty-four to seventy-two hours, will of course depend on its ordinary or preternatural character.

Class III.—Labors of a complex or anomalous character.

Order 1. Labor complicated with uterine hæmorrhage, including those labors where the placenta fully, or only partially presents.

322. Having already treated of those hæmorrhages which occur before and after the birth of the placenta, we shall now briefly advert to the losses of blood we so often witness in abortion; and to those which occur in more advanced pregnancy, or at the full term of utero-gestation. Denman says, that all expulsions of the fœtus before the termination of the sixth month of pregnancy, may be called abortions; but that all expulsions in the last three months are to be considered as labors premature or regular. The practical reason for this distinction, he conceives to be of great importance: before the termination of the sixth month, these cases, generally speaking, neither require nor allow of manual assistance; but in the last three months, they admit of manual interference, if it be required, though not with equal ease; for the longer the time which is wanting to complete the period of utero-gestation, the greater will be the difficulties attending any operation it may be thought necessary to perform. In this rule we do not fully concur, as there are abortions, during the first four months, where hæmorrhage occurs to so great an extent, as would not only endanger but destroy life, were not the ovum removed by artificial help, generally perhaps, by the aid of the fingers. We were lately called to a poor woman in the third month of pregnancy (and the preparation of the ovum is now in the museum of St. Thomas's Hospital), who nearly died from hæmorrhage occurring at this period. On entering the room we were struck with the ghastly and dying appearance of the patient, whose early pregnancy had deterred the medical attendant from making any attempt to bring away the ovum.

323. The hæmorrhage was very excessive and the collapse alarming; of course nothing could be attempted as to the removal of the embryo, in this powerless state of system; and, having poured some nearly pure brandy down the throat, after an interval of about ten minutes vitality was partially restored, but with its restoration there was also a renewal of the flooding. We now introduced two or three fingers of the left hand into the vagina, insinuating them a little distance within the os uteri; here we found the ovum partly adherent and partly detached; with some slight difficulty we entirely separated it from the internal surface of the uterus, and its extraction was easily effected. The flooding immediately ceased, although the recovery was painfully protracted. The exceptions to this rule of Denman's are not unfrequent. Mr. Randall, of Finsbury Circus, lately met with a case of four months' pregnancy, where the placenta was partially adherent to the os uteri, in which the patient would have been lost had not the fœtus been manually extracted.

324. Abortion is a subject entitled to the fullest consideration of medical men, as it is a complaint of common occurrence during pregnancy, and frequently productive of serious injury to the female constitution. It is not invariably happening in weakly and debilitated women, as might naturally be expected; for consumptive patients seldom abort, and it is scarcely possible to point out a more feeble and irritable state. We may remark that weakness, or irritability in general, is seldom a cause of abortion, but some weakness or imperfection originating in or affecting the uterus and its appendages; or a peculiar kind of irritability thence proceeding, distinguishable enough in the female character, by a careful observer, which creates impatience of mind and restlessness of body, in which every occurrence is the source of ungrounded fear and solicitude, and every office is performed with hurry and vexation.

325. Abortions are not very often dangerous in the first five months; but a frequent habit of miscarriage debilitates the system, shatters the constitution, and lays the foundation of chronic diseases of the most obstinate and dangerous nature. In the advanced months the prognosis will be more or less favorable, according to the patient's former state of health; the occasional cause and symptoms with which it is attended. The proximate cause of abortion is the same with that of true labor, viz. a contracting effort of the uterus and abdominal muscles, assisted by the other expulsive powers. The remote causes cannot be explained with precision, as many circumstances, with regard to the nature of impregnation and connexion of the fœtus with the placenta and uterus, are subjects still involved in darkness. They may in general, however, be reduced to whatever interrupts the regular circulation between the uterus and placenta: every cause that excites the spasmodic contraction of the uterus, or other assisting powers; whatever occasions the extinction of life in the fœtus. Amongst the first are, diseases of the uterus; imperviousness or spasmodic constriction of the extremities of the uterine blood-vessels; partial or total separation of the placenta or chorion from the uterus; determination to other parts.

326. To the second general head belong all causes that produce a strong contraction of the elastic fibres of the uterus or of the parts that can press upon it; or that occasion a rupture of the membranes, such as violent agitation of the mind or body; a disease of the membranes; too large a quantity of the liquor amnii; the cross position of the fœtus; its motion and kicking.

327. The third and last head includes the numerous causes of the death of the child, which, besides those referred to in the preceding classes, may be occasioned by diseases peculiar to itself: diseases communicated by the parents; external accidents happening to the mother, or accidents incident to the fœtus in utero; diseases of the placenta or funis; knots and circumvolutions of the chord; too weak an adhesion of the placenta or chorion to the uterus; and every force that tends to weaken or destroy this attachment.

328. As to the treatment, it must be varied according to the particular circumstances of the case; nor is it possible to point out particular indications, or propose any regular plan to be pursued for this purpose. Abortion is often preceded by no apparent symptoms, till the rupture of the membranes and evacuation of the waters announce the approaching expulsion of the fœtus. Either to remove threatening symptoms, or to prevent miscarriage when there is reason to apprehend it, often baffles our utmost skill; because it generally happens that there is a cessation of growth in the ovum, or in other words an extinction of life in the fœtus, some time previously to any appearance of abortion. For instance, in early gestation a woman often miscarries about the eleventh or twelfth week, but the age of the fœtus at this time is generally no more than eight weeks. At other times, when by accident the fœtus perishes, perhaps about the fifth or sixth month, it will still be retained in utero, and the expulsion will not happen till near the completion of the full time.

329. As women who have once miscarried are liable to a recurrence from a like cause, at the same particular period; such an accident in future pregnancies should be guarded against with the utmost caution. On the first appearance of threatening symptoms the patient should be confined to a horizontal posture; her diet should be light and cooling; her mind should be kept as tranquil as possible; a little blood from the arm may be taken occasionally, and opiates administered according to circumstances; but excepting so far as depends on these, and such like precautions, in the way of medicines very little can be done. The medical treatment of abortion must therefore be considered with a view only to the prophylactic cure, and this will consist chiefly in a proper regimen.

330. *Of the proper regimen during pregnancy.*—Women when pregnant should live a regular temperate life; moderation in eating and drinking should be carefully observed, and every thing having a tendency to disagree with the stomach should be avoided; in other respects the manner of life should be much as usual. If complaints occur they should be treated as at other times, only guarding against such things as, by violent operation, may endanger miscarriages. If the patient has formerly been liable to this accident, the cause should be carefully considered and suitable remedies applied; if plethoric, for instance, a little blood may be advantageously abstracted, she may live abstemiously, and preserve the utmost tranquillity till she gets beyond the dangerous period. If she be weak, delicate, and nervous, bark, light aromatic bitters, mineral waters, and the cold bath (if able to bear it) will be the best remedies. The cold bath has in many cases cured the most obstinate fluor albus, and sometimes even sterility itself, and in relaxed habits, disposed to miscarriage, when every other means has failed it has done considerable service; the practice may safely be continued for several months after conception, when it has been early begun or the patient has been accustomed to it. Such a shock will, however, have very different effects on different constitutions, and on persons not accustomed to the cold bath; hence it is an expedient by no means to be indiscriminately used in the pregnant state.

331. Abortions that happen in early gestation, and that come on suddenly, without any presaging sign, can only be prevented by avoiding all occasional causes, by counteracting morbific dispositions, and by confinement to a horizontal posture for some time before and after the critical period is over. When a venereal taint in the parents is suspected to be the cause, either of abortion or the death of the fœtus, the like accident can only be prevented by putting both parties on a mercurial course.

332. Pregnant women require a free pure air; their amusements should be often varied; their companions should be agreeable and cheerful; their exercise should be moderate, and suited to their inclination, constitution, and the season; they should avoid crowds, confinement, and travelling over rough roads in a carriage. Women should with the utmost care guard against confining the breasts or abdomen; and they should keep themselves as loose and easy as possible through the whole term of gestation. When the abdomen is pendulous, towards the latter months, a gentle support by a proper bandage will prove useful; and the woman, when fatigued, should occasionally through the day indulge in resting on a bed or sofa.

333. *Of the floodings occurring nearly at the full term of utero-gestation, and at the commencement of labor.*—There is, perhaps, no circumstance attendant on parturition which excites such solicitude in the accoucheur, or exposes the patient to such imminent danger, as repeated or large losses of blood at the termination of pregnancy, or in the commencement of labor. We can readily conceive how uncertain and inefficient the treatment of such floodings must have been, prior to the appearance of Dr. Rigby's most excellent and invaluable work, who tells us that most of the authors whom he had read on this subject describe these cases as peculiarly embarrassing, acknowledging that they have always been at a loss, when such have occurred to them, to determine with any degree of certainty and satisfaction which of the two methods of practice hitherto recommended it has been most proper to adopt, whether to endeavour to restrain the discharge by the means before mentioned for that purpose, and leave nature by her own efforts to expel the child, as is the case in floodings of the early months; or at once to introduce the hand into the uterus and bring it away by art. This doubt about the propriety of waiting, or the necessity of removing the contents of the womb, they say, is ever owing to the uncertainty of knowing the quantity of blood that has been lost; and, if it were known, to the impossibility of ascertaining the degree of loss a woman might sustain without manifest risk of life. These statements Dr. Rigby proved to be incorrect, observing that a knowledge of the true causes that produce floodings will give us all the information, which may be considered as the first requisite towards an improvement in the practice; for these floodings arise from two very different causes

which are very different in the danger they produce, and which require a very opposite method of treatment. The separation of the placenta from the uterus before the delivery of the child, and the consequent opening of its vessels, must be looked upon as the proximate cause of every considerable discharge of blood from the womb at that time; but this premature separation may be produced by very different causes. These causes it is necessary to understand, that we may see the reason why the same apparent complaint should very often so widely differ in its termination and treatment.

334. There is no particular part of the uterus to which nature seems constantly and uniformly to fix the placenta; it is nevertheless for the most part so situated, that if the woman be healthy, and no accident befal her, it does not separate until the full term of pregnancy, nor then before the entire expulsion of the child; after which it becomes disengaged from the uterus, and is thrown off, making room for its entire contraction, which shutting up the mouths of the vessels effectually prevents any considerable loss of blood; for which purpose it is plain it must be fixed to some part of the womb which does not dilate during labor, namely, to the fundus or side of it. In this case, then, when a flooding comes on before the delivery of the child, it is obvious that the separation of the placenta must be owing to some accidental circumstance, to violence done to the uterus by blows or falls, to some peculiar laxity of the uterine vessels from the badness of habit, or fever, or to some influence of the passions of the mind, suddenly excited, such as fear, anger, &c.

335. But, from the uncertainty with which nature fixes the placenta to the uterus, it may happen to be so situated, that when the full term of pregnancy is arrived, and labor begins, a flooding necessarily accompanies it, and without the intervention of any of the above accidental circumstances; that is, when it is fixed to that part of the womb which always dilates as labor advances, namely, the collum and os uteri; in which case it is very certain that the placenta cannot, as before described, remain secure till the expulsion of the child, but must of necessity be separated from it, in proportion as the uterus opens; and by that means a hæmorrhage must unavoidably be produced.

336. That floodings which arise from these two different causes, which may be distinguished by the names of accidental and unavoidable, though they may appear exactly similar in their first symptoms, should terminate very differently if left to nature, assisted only by the palliating means before mentioned, cannot seem strange; nor can it be a doubt that, of these two kinds of floodings, only one of them, namely, that which is produced by an accidental separation of the placenta, can be relieved by the use of these palliatives; and that the other, in which the placenta is fixed to the os uteri, and the flooding is therefore unavoidable, cannot possibly be suppressed by any other method whatever than the timely removal of the contents of the womb; for, supposing the discharge to be for a while restrained, by bleeding, medicine, cool air, &c., it will inevitably return when nature is so far recovered as again to bring on labor; in the first case, if hæmorrhage have been checked by the use of the above means, it is not impossible but labor may come on, and the child be safely expelled by the natural pains before it returns; or, if it should return, it may not increase in quantity, as, in this case, very probably the separated part of the placenta which occasions the discharge remains nearly the same; whereas, in the other case, in which the dilatation of the os uteri produces the separation of the placenta, every return of pain must be a return of the bleeding, and it must become greater and greater as the uterus opens more and more; and the placenta is in proportion detached, till it increases to a degree that exhausts the patient, and she dies before nature has been able to expel the child. That such must inevitably be the progress and event of floodings, arising from such a cause, if left to nature, is too obvious to be further insisted on.

337. Admitting then that floodings are produced by these two different causes, and that they require a treatment so widely different, we cannot be at a loss, says Dr. Rigby, when such do occur to us and we have discovered the particular cause from which they arise, how to act; as in the one case we shall be encouraged to wait, and to make use of such means to restrain the discharge as will be more particularly mentioned hereafter; and in the other we shall not hesitate to have recourse to delivery by turning the child. Dr. Rigby has not only fully proved the necessity of turning the child, whenever the placenta is fully attached over the os uteri, but he has also established the value of the practice of rupturing the membranes, when flooding appears before delivery, and the placenta is not to be felt. Of sixty-four cases of accidental hæmorrhage, treated in this way, every patient was saved, although some had lost a large quantity of blood, and were very faint, previously to the operation being performed. In many indeed the flooding was trifling; but even in these sufficient to excite some degree of alarm.

All practitioners are now fully agreed that, whenever the placenta wholly presents, the best chance of saving the patient is by delivering at the most suitable opportunity; and that in accidental hæmorrhage the most successful practice is to rupture the membranes, and leave the case to be perfected by the natural powers; provided the flooding cease on the evacuation of the liquor amnii. There is still, however, a diversity of opinion as to the course to be pursued where the placenta is only partially adherent to the os uteri, in which some accoucheurs invariably resort to artificial delivery; while others, and amongst them Dr. Francis Ramsbotham, pursue a different plan. If not more than one-third of the os uteri is occupied by placentar attachment, an attempt is to be made to relieve the patient by evacuating the waters, and allowing time for the uterus to act, carefully watching the patient lest the draining be kept up after the membranes have been ruptured. Dr. R. urges, in support of this practice, the great fatality which has attended placenta, and partial pla-

centa presentations, generally in his practice, when treated by turning; and the great danger of suddenly evacuating the uterus at any time, and especially under the state of faintness produced by loss of blood. After the evacuation of the waters, besides the blood-vessels of the uterus being very much diminished in their calibre, and allowing less blood to circulate through them, if uterine action come on, the head will, in passing through the os uteri, close by its pressure the mouths of the bleeding vessels, and in this manner suspend the hæmorrhage; and, should the contractions continue, the child is ultimately expelled. Provided, however, the uterus does not act sufficiently strongly to restrain the hæmorrhage, and expel the fœtus, it will be more or less flaccid, and there will be but little or no impediment to the passage of the hand into the uterus, and the delivery by the feet; the only resistance being the contracted uterus, when contraction has not taken place there can be no difficulty; the case is perhaps more likely to terminate favorably when turning is had recourse to after the water has been evacuated some time, and the uterus has slightly embraced the body of the child, than when a more hasty delivery is effected; because in that case the uterus is to a certain degree lessened in volume, there is not so sudden a diminution of bulk, and the dreaded collapse is not so likely to occur. Dr. R. has seen many cases in which this plan has been adopted, when the patient's existence was depressed to its lowest ebb, and where it has been attended with the happiest results. At the same time he presses on the recollection, that, should hæmorrhage continue after the perforation of the membranes, so as to endanger the patient's life, there is but one mode to be adopted, that of as speedy a delivery as possible.

Order 2. Labor complicated with convulsions.

338. Cases of puerperal convulsion bear a strong analogy to epileptic fits; so much so that it is nearly impossible to distinguish them at first sight, excepting from the different degree of violence attending each; the fit of puerperal convulsions being much more violent than any fit of epilepsy. Indeed, the paroxysm is so violent that a woman, who, when in health, was by no means strong, has shaken the room with her exertions.

339. Puerperal convulsions may arise at any period between the sixth month and the completion of labor; rarely or never do they occur before the sixth month. They may arise as the first symptom of labor—in the course of labor—or after the labor is in other respects finished. Puerperal convulsions always occur in paroxysms, and those paroxysms occur periodically, like labor-pains: so that there is a considerable time, perhaps two hours, between the two first attacks: after this they become more frequent. They not only occur with the labor-pains, but in the intervals; and, whether there have been labor-pains or not before they come on, we shall always find the os uteri dilated, and it is sure to become dilated from the continuance of these convulsions; and at length, if the woman be not relieved, and the convulsions continue without destroying her life, the child is actually expelled without an labor-pains. In severe cases, where death has occurred previous to the birth of the child, it has been found partly expelled by the contraction of the uterus; which power had been exerted even after the death of the mother. In one case the whole child was expelled except the head.

340. It is a disease depending on the uterus, and brought on by labor-pains; or, if arising before them, is of itself capable of expelling the child, if the woman survive long enough. It occurs in all presentations; sometimes with the first child, and sometimes with those born afterwards. It resembles hysteria, as well as epilepsy; but is more violent than either. No force can restrain a woman when in these convulsions, be the same woman naturally ever so weak. The distortion of the countenance, also, is beyond any thing that can be conceived; in regard to deformity, surpassing any thing the imagination of the most extravagant painter ever furnished: nothing bears any resemblance to the progress of this disease; the rapidity with which the eyes open and shut, the sudden whirlings of the mouth, are altogether inconceivable.

341. These convulsions are by no means external only; respiration is affected with a hissing and catching. The patient stretches herself out, and immediately the convulsion begins. The next symptom appears after the convulsive motions have continued with their utmost violence for some time: the woman foams at the mouth, and snores like an apoplectic patient, indicating great fulness of the cerebral vessels. These symptoms are succeeded by a comatose sleep, from which she awakes astonished, when told what has happened, not being aware that she has been in any fit: and then she will fall into another fit, out of which she will again recover as before. It rarely happens that the understanding is taken away in this disease, until it has been repeated several times. In the fit, the skin becomes dark and purple, proving that the circulation through the lungs is not free: this gradually disappears after the subsidence of the fit. The uterus, as well as the respiratory muscles, is affected: this may be known by introducing the hand when the convulsions come on; the uterus will contract, but with a tremulous indecisive force, perfectly different from its usual contraction.

342. There are two cases of puerperal convulsions which are very distinct: one is a convulsion dependent on some organic affection of the brain; the other on an irritable state of the nervous system. Where puerperal convulsion arises from the former, but more especially from fulness of vessels or extravasation, it is always preceded by some symptoms, which, if watched, will enable us to relieve the patient, provided that we are very quickly summoned.

343. In a patient strongly disposed to this disease there will be a sense of great fulness in the region of the brain, which amounts even to pressure; giddiness in the latter periods of pregnancy; and a sensation of weight when the head stoops forward, which gives her the idea that she will be unable to raise it again; imperfect vision; and dark or luminous bodies will be dancing

before the eyes. This state of the eyes denotes fulness of the vessels of the head more surely than any other symptom; and, if allowed to continue, will lead to extravasation and puerperal convulsions. The disturbed vision is a very important symptom, and must never be passed by. If attended to early, even though symptoms of the complaint are present, still it may, by timely assiduity on our part, be prevented from ending in premature labor. Here repeated bleedings and purgatives are all in all; the sole object being to remove stimuli. After bleeding, and before any aperient is given by the mouth, we should inject, per anum, a solution of soft soap in warm water; it is the quickest and the surest means; after this administer a purgative mixture, containing Epsom salts and manna. By these means, that is, by bleeding, purging, and abstinence from all solid food and wine, the quantity of circulating fluid in her body is diminished, and she gradually recovers.

344. When convulsions arise from a generally irritable state of the nerves, it is difficult to distinguish the disease before it becomes established. It is most frequent in large towns, and in women who lead an indolent life; hence it is most frequently found in the first circles of fashion: and there is one grand circumstance which has great influence in its production—viz. a woman's being pregnant when she should not. Obliged perhaps to live secluded from society for some months, she reflects and broods over every thing which relates to her situation, and which gives her pain; she recollects that she is not to enjoy the society of her babe, but, on the contrary, will be obliged perhaps to part with it for ever: she is afraid of her situation being known, and that she will be considered an outcast from society. In this way will she brood in solitude, till at last the mere irritation of labor will be sufficient to induce convulsions. The difference between this kind of puerperal convulsions and the other, does not probably consist in any thing visible; it is not possible to tell the difference exactly; but, just as it is coming on, the woman will complain of a violent pain in her head or stomach, which is expressed in the same terms by all women; they all say that they cannot survive a return of the pain. The mode of treatment will not essentially vary from that already mentioned: our plan should however be less active; and opiates should succeed the primary measures.

345. These observations, be it remembered, relate to convulsions antecedently to labor. We now proceed to the same disease during labor. It has sometimes happened that a woman has died of the first convulsion: but it more generally happens that a number come on in succession, arising either after or before delivery. The patient very rarely dies in the fit, though she dies from the convulsions: she dies in the comatose stage which succeeds the convulsion; and if we be suddenly called to a patient in this state, where we are unable to learn the circumstances of the case, and we evidently see that there is great fulness about the head, we should immediately open a vein, and draw blood largely, being regulated by the appearance of the patient, and by what we can learn from the by-standers. From twelve to twenty ounces may be the extent of the first bleeding; if the disease continue, and the os uteri be not at all dilated, the convulsions not subsiding, and the pulse in such a state as to warrant the measure, we should bleed again and again. Some practitioners have with the greatest advantage taken sixty ounces of blood in a day. A woman in this state will bear very large divided bleedings. This takes off the pressure of the distended blood-vessels from the brain, and presents the chance of extravasation. This being promptly effected, the head must be shaved, and a large blister applied over the whole cranium. The next means of relief is to get the bowels into action as quickly as possible; first, by throwing up a solution of soft soap, and then by giving her to drink a solution of some neutral salt in infusion of senna.

346. If it be a case of convulsions depending upon irritation, we may certainly do something more by the use of opiates; and in this case we must be more cautious in abstracting blood. The proportion of blood removed must be small in this case, compared with that in plethora. Eight or ten ounces will be a full bleeding; and, if it be necessary to take more, we may apply leeches to the temples, never neglecting to keep the bowels freely opened. It has been directed that the patient be placed in a warm bath, but experience contradicts its use: the fits have been found to be more violent in it, and the patient is liable to bruise herself, or be otherwise much injured.

347. It is an extremely dangerous disease; her brain cannot bear the excessive pressure of her situation; opium therefore, in cases of irritation, is proper, and should be given to the greatest possible extent. With this we may join the affusion of cold water. This, when resolved on, must not be done by sprinkling a little on the patient's face; but we must have both a full and an empty pail, the patient's head being brought over the side of the bed, and, before the fit comes on, we may, as in other convulsions, detect its approach by observing the intercostal muscles, the violent action of which will warn us that no time must be lost; when we should immediately dash the pail-full over the head. Whenever this complaint appears at or near the time of labor, it is uniformly proper to deliver: to dilate the os uteri, and deliver immediately. This is the only cure for puerperal convulsions.

348. If convulsions occur some days after labor, it should be treated as in other cases of the same disease.

Order 3. Labors complicated with rupture of the uterus, vagina, perinæum, &c.

349. These cases are very rarely occurring in well managed parturition, and they will require only a brief notice. Dr. Denman attributes one occurrence of lacerated perinæum, in his own practice, to extreme restlessness and irritability of the patient, preventing the necessary precautions from being used. He further says that the frequent occurrence of this laceration in the human species, allowing that it is in some cases

and in some degree unavoidable, ought to be imputed to some accidental cause, or to error in conduct, rather than to any peculiarity in the construction of the part, or in the circumstances of their parturition; because, when women were delivered without assistance, he has not in any case observed any very considerable laceration. We believe that the power necessary to be exerted in parturition is, excepting in some rare instances, nicely proportioned to the degree of resistance which it has to overcome, and we of course concur in the opinion expressed by Dr. Denman in the preceding lines. Laceration of the perinæum is most frequently occurring from the premature and sudden propulsion of the head through the external parts, previously to their complete dilatation, when the perinæum is thick and rigid. We may add to this cause the voluntary force, or bearing down the pains, so common at the time of parturition, in the performance of which women exert a considerable degree of voluntary power, often indeed their whole strength, with the hope and intention of finishing their labors speedily. This accident therefore rarely happens in very slow or difficult labors, whatever may be the size or position of the head of the child.

350. It is generally recommended, when supporting the perinæum, to interpose a soft napkin between it and the hand; from this injunction we dissent, as it is manifest if the napkin be three or four times doubled, and it cannot very well be less if it afford any soft cushiony support to the part, the accoucheur must be in ignorance as to the precise condition of the perinæum, it may or it may not be in a fit condition to allow the passage of the head: laceration almost invariably occurs, not because the head is too large, or from its passing in any particular direction, but because it passes too speedily or presses, as we have before remarked, too violently or suddenly, upon the undilated parts: of all these circumstances, the naked palm of the hand will enable us to judge much more correctly than if a napkin be interposed. We have seen one case of laceration arising from this want of correct information, the head passed down to the outlet suddenly, the attendant immediately supported the perinæum by a soft napkin; the perinæum was lacerated, and the child immediately thrust into the world.

351. The cure of a lacerated perinæum is very tedious; and, although no danger arises from the accident, yet if it divide the partition or septum between the vagina and rectum, the patient is rendered truly miserable; for, having little or no power of retaining her fœces, she cannot go into society.

352. Sutures have been advised in the treatment of lacerated perinæum, it being supposed that the parts might be retained in opposition sufficiently long to establish firm union between them: they have not been attended with success, as the ligatures have sloughed away, and the patient has been left in a worse condition than before. We have seen two instances of lacerated perinæum, and in one, where the rectum and vagina ,communicated, we induced tolerably firm union in six months; quite enough to enable the lady to retain her fœces, and to perform her usual duties. This lady maintained the recumbent position with the thighs closed during nearly the whole of this time; the wound was occasionally touched with the argenti nitras and the nitric acid lotion. Eighteen months after the occurrence of the accident she was again confined; and, although there was a good deal of relaxation about the parts, they did not separate: since this period no inconvenience worth mentioning has been experienced.

353. *Laceration, or rupture of the uterus.*—Dr. Merriman says that this accident has happened from a morbid state of the uterus, before the period of utero-gestation has been completed, and the fœtus, having escaped into the cavity of the abdomen, forms what is called an extra-uterine conception of the ventral kind. Sometimes the laceration of the uterus appears to have been produced by the untoward situation of the uterus in the pelvis; hence ulceration has taken place, and the fœtus has been transferred into the cavity of the pelvis, and finally discharged through the vagina or rectum in a dissolved, or putrid state.

354. But more commonly the rupture is occasioned during labor from the violence of the pains acting irregularly, or impetuously, against some projecting part of the child; upon which the uterus splits: and this is more likely to happen in cases of distorted pelvis, or of preternatural presentation of the child. Or it may be occasioned by the rude and forcible attempts of the operator to turn the child in utero; or by inconsiderate and violent endeavours to introduce instruments; and sometimes the immense bulk of an emphysematous child, in passing through the os uteri and vagina, has torn these parts asunder.

355. If the rupture of the uterus has taken place before the full term of gestation is accomplished, and while the os uteri is undilated, it is obviously impossible to afford the patient any kind of manual assistance; the case must therefore be trusted to nature, and, under such circumstances, some women have wonderfully recovered; the child, in a dissolved state, having, in a few instances, after months or years, made its way through the parieties of the abdomen by the process of ulceration. The operation of gastrotomy has been recommended, to give nature an earlier opportunity of getting rid of the burden, but the success of such an operation is doubtful.

356. When a laceration happens during the pains of labor, the following symptoms usually occur:—

1. A sense of something giving way internally preceded by a very severe pain, generally described as a cramp.

2. A sensation of great languor and debility.

3. A speedy, sometimes an instantaneous, vomiting of the contents of the stomach.

4. A vomiting of a brownish, or coffee-colored, fluid.

5. A very quick, weak, fluttering, pulse: a cold sweat; great difficulty of breathing; an immediate cessation of the labor-pains.

357. If now the patient is examined, per vagi-

num, it will generally be found that the presenting part of the child, which had before been pressed some way into the pelvis, is retracted, and no longer within reach of the finger; and if the hand be carried through the os externum, in order to make a more accurate examination, the child will be discovered to have passed, either wholly or in part, through a rent, into the cavity of the abdomen. There are, however, a few instances in which the child has remained in utero, notwithstanding the laceration.

358. The mode of practice recommended by many authors, in these unfortunate cases, is to give the patient a chance of recovery by introducing the hand through the rent till it reaches the feet of the child, wheresoever they are to be found, and extracting the child footling. In a few instances this plan has succeeded in saving the patient's life, but more commonly all that is done proves unavailing, and death speedily ensues.

359. The practice here recommended was countenanced by Dr. Denman in his Introduction to Midwifery; but circumstances have, since that time, induced him to reconsider this case more particularly; and, after much enquiry and reflection, he seems to be convinced that, upon many occasions, the patient would have a better chance of recovery, if the case were resigned to the natural efforts, than by any operation or interposition of art. Either of these plans must be preferred according to circumstances. If, in a case of this kind, it should be found that the child had only in part escaped into the cavity of the abdomen, we should consider that it was the best practice to bring down the feet, if they were within reach, or to deliver by means of the forceps, if the situation of the head allowed of the application of this instrument. And even if the child had been wholly forced through the rent, that it would be expedient to extract it by the feet, provided there was a ready passage for the hand into the cavity of the abdomen, and the accident had not been of long duration; but if some hours had elapsed after the parts had given way, or if there were a difficulty in passing the hand, on account of the contraction of the uterus, it would then perhaps be more prudent to leave the event to nature.

We have now concluded the three principal divisions of our subject; and the circumstances, and some of the diseases, immediately succeeding parturition alone remain to be noticed: we shall first allude to

The Treatment after Delivery.

360. Immediately after the placenta is expelled, the finger ought to be introduced into the vagina, to ascertain that the perinæum, or recto-vaginal septum, be not torn, and that the uterus be not inverted. Then, if the woman be not much fatigued, or if she be prone to hæmorrhage, Mr. Gaitskell's belt, supposing it to have been previously applied, may be gently tightened. We are not greatly inclined to the practice of turning the patient on her back and submitting her to the process of fastening round the abdomen a broad bandage, intended to give a feeling of agreeable support. We believe, in the majority of instances, if the placenta has been slowly extracted, and if the uterus be afterwards slightly grasped by the hand, firm and permanent contraction will be induced: at least we have not unfrequently known partial hæmorrhage to arise from the disturbance of circulation produced by this putting on of the bandage. Circumstances must, however, in all these cases, regulate our procedure; and, if any additional comfort or security can arise to the patient from this application of the abdominal roller, it certainly ought not to be neglected. The wet sheet is also to be pulled from below her (vide Burns's Midwifery, p. 387), and an open flannel petticoat to be put on; it has a broad top band, and is introduced and pinned like the bandage. A warm napkin is then to be applied to the vulva, and the woman raised in an easy posture, having just so many bed-clothes as make her comfortable. If she desire it, she may now have a little panada, after which we leave her to rest. But, before retiring, it is proper to ascertain that the bandage be left sufficiently tight, that there be no considerable hæmorrhage, and that the after pains are not coming on severely. It is also proper to mark the state of the pulse, and to leave strict directions with the nurse that every exertion and all stimulants be avoided.

361. Having thus simply stated what appears to be necessary, I must next say what ought to avoided. It is customary with many nurses to shift the patient completely; and, for this purpose, to raise her to an erect posture. Now this practice may not always be followed by bad consequences, but it is very reprehensible; for the patient is thus much fatigued, and if she sit up, even for a short time, hæmorrhage or syncope may be produced. The pretext for this is generally to make the patient comfortable; and, indeed, if the clothes be wet with perspiration or discharge, there may be some inducement to shift her. But this ought to be done slowly, without raising her, and, if she have been fatigued, not until she has rested a little. Another bad practice is the administration of stimulants, such as brandy, wine, or cordial waters. I do not deny that these, in certain cases of exhaustion, are salutary; but I certainly maintain that generally they are both unnecessary and hurtful, tending to prevent sleep, to promote hæmorrhage, and excite fever and inflammation. A third practice, no less injurious, is keeping the room warm with a fire, drawing the bed-curtains close, increasing the bed-clothes, and giving every thing warm to promote perspiration. This is apt to produce debility, and many hysterical affections, as well as a troublesome species of fever, which it is often difficult to remove. It also renders the woman very susceptible of cold—a shivering fit is very readily excited. Lastly, talking, and noise of every kind, is hurtful, by preventing rest, occasioning head-ache or palpitation, as well as other bad symptoms.

362. At our next visit, which ought to be within twelve hours after delivery, we should enquire whether the patient have slept, and ascertain that the pulse be not frequent; that the after pains have not been severe; nor the discharge copious. We should also particularly enquire if she have made water; and if she have not, by

have a desire to do so without the power, a cloth dipped in warm water and wrung pretty dry, should be applied to the pubes. If this fail, the urine will often be voided if the uterus be gently raised a little with the finger; or the catheter may be introduced. There are two states in which we are very solicitous that the urine be voided: the first is when the woman has much pain in the lower belly, with a desire to void urine; the second is after a severe or instrumental labor.

363. A motion should be procured within twenty-four hours after delivery, either by means of a clyster or gentle laxative. If the patient usually have the milk fever smartly, or the breasts are disposed to be painful and tense, a mild dose of some saline laxative is better than a clyster. But if she be delicate, and have formerly had little milk, a clyster is to be preferred. If she is not to suckle the child, then the laxative should be rather brisker, and may be repeated at the interval of two days.

364. After delivery there is a discharge of sanguineous fluid from the uterus for some days, which then becomes greenish, and lastly pale, and decreases in quantity, disappearing altogether within a month, and often in a shorter time. This is called the lochial discharge. During this time, it is necessary that the vaginal and external parts be daily washed with tepid milk and water.

365. During the latter end of gestation, milk is generally secreted in a small quantity in the breasts, and sometimes it even runs from the nipples. After delivery the secretion increases, and about the third day the breasts will be considerably distended. Many women, indeed, complain at this time of much tension and uneasiness; and there is usually some acceleration of the pulse. A pretty smart fever may even be induced, which is called the milk fever. The best way to prevent these symptoms from becoming troublesome is to keep the bowels open, and apply the child to the breasts before they have become distended. This may generally be done twelve hours after delivery.

366. The diet of women in the puerperal state ought to be light; and, if they are not to nurse, liquids should be avoided, the food must be of the dry kind, and thirst should be quenched rather with fruit than with drink. If they are to nurse, the diet, for the first two days, should consist of tea and cold toasted bread for breakfast, beef or chicken soup for dinner, and panada for supper; toast or barley water may be given for drink, but malt liquor should be avoided. Unless the patient be feeble, and at the same time have no fever, wine should not be allowed for the first two days; a little may then be added to the panada or sago, which is taken for supper; and a small glass, diluted with water, may be taken after dinner. A bit of chicken may be given for dinner, and, in proportion as recovery goes on, the usual diet is to be returned to.

367. The time at which the patient should be allowed to rise a little, to have the bed made, must be regulated by her strength and other circumstances. It ought never to be earlier than the third day; and in a day or two longer she may be allowed to be dressed and sit a little, but even in the best recovery, and during summer, the woman ought not to leave her room within a week. She ought not to go out for an airing, in general, till the third week. In cold weather, and when the patient is delicate, she must be longer confined. By rising too soon, and making exertion, a prolapsus uteri may be occasioned, and still more frequently the lochia are rendered profuse, and the strength impaired. If there be, or have formerly been, the smallest tendency to prolapsus, it is absolutely necessary to keep the patient very much for some time in a recumbent posture on a sofa, avoiding, however, that degree of heat which relaxes the system. It is also necessary to stimulate the uterine lymphatics to absorption by a smart purgative once in three or four days, to bathe the external parts with rose water, having a third part of spirits added to it; and at the end of a fortnight begin a tonic, mixed with a mild diuretic.

368. *Of after pains.*—Few women proceed through the early part of the puerperal state without feeling attacks of pain in the belly, which are called after pains. These are generally least severe after a first labor. They proceed from the contraction of the uterus in an irregular manner, excited by the presence of coagula or other causes; and each severe pain is generally followed by the expulsion of a clot. They come on usually very soon after delivery, and last for a day or two. They are often increased when the woman first applies the child to the breast. They are distinguished from inflammation of the uterus or peritonæum, by remitting or going off. The belly is not painful to the touch, the uterine discharge is not obstructed, the patient has no shivering nor vomiting, the milk is secreted, and the pulse is seldom frequent. When the pulse is frequent, then we must always be on our guard; for, if this be the case before the accession of the milk fever, the patient is not out of danger; and, if any other bad symptoms appear, we must be prompt in our practice. After pains may also be caused by flatulence and costiveness, which we know by the usual symptoms; but a combination of this state, with uterine after pains, is often attended with a frequency of the pulse, and may give rise to a fear that inflammation is about to come on, but other symptoms are absent. Uterine after pains are relieved by opiates and fomentations; and, if protracted, by a purgative, and this is always proper when the pulse is frequent. A severe constant pain in the hypogastric region is sometimes produced by an affection of the heart, and proves fatal, yet the uterus is found healthy. Upon this subject it may not be improper to mention, that a young practitioner may mistake spasmodic affections or colic pains for puerperal inflammation; for in such cases there is often itching and sensibility of the muscles, which renders pressure painful. But there is less heat of the skin, the tongue is moist, the pulse, though it may be frequent, is soft, the feet are often cold, the pain has great remission if it do not go off completely, there is little fullness of the belly, and the patient is troubled with flatulence.

369. It requires laxatives, antispasmodics

anodyne clysters, and friction with camphorated spirits. Oil of turpentine acts both as a laxative and antispasmodic. In doses of half an ounce, it often relieves spasmodic pain in the stomach or bowels. Blood drawn in this disease, after it has continued for some hours, even when the woman is not in child-bed, is sizey; and is always so in the puerperal as well as the pregnant state, although the woman be well.

370. It is necessary to attend carefully to the duration and situation of pain after delivery, and to the symptoms connected with it. For it may proceed from inflammation of the viscera; or in some cases it is felt near the groin, and may be the forerunner of swelled legs; or about the hip, ending in a kind of rheumatic lameness; or, in consequence of the application of cold, pain may be felt in some part of the recti and oblique muscles, which, if not removed by fomentations and frictions, may end in tedious abscess, exciting hectic fever. Such an abscess ought to be opened with a lancet or caustic.

371. Rheumatism affecting the muscles of the abdomen and pelvis is accompanied by less fever than puerperal inflammation, and wants the other symptoms. The pain is shifting and acting, or gnawing, though sometimes it is sharp like a stitch. It is relieved by friction with laudanum, by sinapisms, and by mild diaphoretics, bark, and other usual means. When speaking of rheumatic pain it may not be improper to mention, that chronic rheumatism, especially of the extremities, is very troublesome when it occurs after parturition. It requires the usual remedies. Cod-liver oil, in doses of half an ounce three times a day, has been much recommended. I have formerly noticed those pains in the limbs which may succeed the use of the crotchet.

372. *Of the milk fever.*—The secretion of the milk is usually ushered in by a slight degree of fever, or, at least, a frequency of the pulse. But sometimes it is attended with a smart febrile fit, preceded by shivering, and going off with a perspiration. This attack, if properly managed, seldom continues for twenty-four hours; and, during this time, the breasts are full, hard, and painful, which circumstance distinguishes this from more dangerous fevers. Sometimes, during the hot fit, there is a slight delirium. A smart purge generally cures this disease, and is often used in plethoric habits, on the third day after delivery to prevent it. Mild diaphoretics during the hot stage are also proper. Applying the child early to the breats is a mean of prevention.

373. We have great pleasure in laying before our readers the following successful case of complete extirpation of the uterus: the propriety of so bold and difficult an operation has been much questioned, yet we feel assured that in diseases of the womb, otherwise irremediable and fatal, this measure, adopted with discrimination and executed with skill, may preserve a life which without it would certainly be sacrificed. The author of this paper is indebted to Dr. Blundell, Lecturer on Physiology and Midwifery, Guy's Hospital, for the subjoined particulars, whose ability and zeal in the diffusion and improvement of obstetric science deserves, and will obtain, higher praise than it is in his power to bestow. It is proper to observe that this is the second time Dr. Blundell has performed this operation: in the former instance the patient died.

374. Mrs. M., at fifty, the mother of two children, the younger of which is sixteen years old, with a uterus about as large as a goose's egg, and a lax vagina, was seized with leucorrhœal discharges and frequent eruptions of blood from the womb; so that for six or seven months together she was scarcely ever free from flooding more or less copious, always increased by bodily exertion and generally succeeded by syncope. Though not prone to speak hyperbolically, she states that on repeated occasions the bleeding was so excessive, that it soaked through a bed twice as thick as an ordinary sofa cushion, and formed a small pool on the floor beneath. It may be difficult to conceive whence so large a quantity of blood could be derived, yet it is her own considerate opinion that for weeks together, she must have lost from half a pint to a pint of blood daily. Her person is short and broad, her complexion apparently of the sanguine kind, and her digestive organs on the whole more powerful than we generally find them under uterine disease. Her strength being much reduced, her appearance exsanguineous, frequent faintings occurring, and no relief having been obtained under the care of three or four respectable practitioners, she was referred to Dr. Blundell, who found on examination an enlargement and induration of the os uteri and the adjacent portion of the vagina, extending perhaps through one-fourth part of its length above, about two-thirds of the mouth of the womb being already destroyed by incipient malignant ulceration. Under these circumstances, Dr. Blundell informed her that extirpation of the diseased structure, though not disproved to be dangerous in a high degree, comprehended her only remaining chance of life. After deliberating for two or three days, and from the occurrence of another large hæmorrhagy, being entirely confined to her bed, she determined to submit to the operation. The bladder and the intestines having been thoroughly cleared of their contents, she was placed without ligature or restraint of any kind in the usual obstetric position, on the left side, close upon the edge of the bed, with the shoulders forward, the loins posteriorly, the knees and bosom approximated, so that the thighs lay before the abdomen, the spine somewhat incurvated, and the front of the body facing a little toward the bed; in a word, the members of the body were composed much after the same manner as the fœtus in utero. The operator then kneeling close at the foot of the bed, the index and second finger of his left hand were carried along the back of the vagina to the line of union between the diseased and healthy structure. This accomplished, by means of a pointed blade with cutting edge, not unlike a dissecting scalpel, mounted upon a stem handle ten or eleven inches in length, stiff yet flexible, the fore finger of the left hand was, as it were, converted into a cutting point, the blade, for this purpose, being carried about one-eighth of an inch beyond the

tip of the finger. Thus a transverse opening was gradually made through the back of the vagina, towards the front of the rectum, into the recto vaginal portion of the peritonæal cavity, the knife being frequently withdrawn below the tip of the finger and the part delicately investigated by the finger so as to ascertain when the vaginal texture was cut through. An opening as large as the orifice of the urethra having in this manner been warily effected, and the knife being drawn down, the index finger was made into a kind of dilator, which bearing out through the aperture, enlarged its dimensions without the risk of wounding any of the contents of the peritonæum. The knife being again raised, so that its point was guarded by the tip of the index, and its cutting edge advanced beyond the side of the finger, so as to communicate to it laterally a cutting power, and thus convert it into a temporary knife possessing the advantage of sensibility; the incision was carried through the vagina transversely, to the root of the broad ligament on the left or under side of the pelvis. It was now easy by reversing operations, and communicating the cutting power by means of the mounted blade, to the fore-finger laterally on the other side, to carry the transverse incision through the vagina, up to the root of the broad ligament on the right or superior side of the pelvis. At this time the intestines could be felt, and steadiness and caution became of great importance. The transverse incision through the back of the vagina having been effected in this manner, without injury to contiguous parts, the whole of the left hand was cautiously, yet resolutely, passed into the vaginal cavity below, the first and second fingers were carried through the opening, and so far advanced that their tips were nearly brought into contact with the abdominal integuments, an inch or two above the symphysis pubis, and posteriorly they reached to the vicinity of the fundus uteri. The uterus itself could not, however, in this instance, owing to its lubricity and rotundity, be brought down by them; it was therefore necessary, under guard of the fingers, which lay on the back of the womb, to insert a double hook into the middle of its body. This was attended with little pain to the patient, and then, by the action of the hook, the entire uterus being cautiously drawn towards the point of the coccyx, while at the same time the fingers were urged onwards and incurvated over the descending fundus, this part of the hand, so important in the whole operation, was used as a blunt hook, by means of which the womb was retroverted into the hollow of the palm, just within the genital fissure. It was now in great measure under view, its fundus lying in the vicinity of the coccyx, and its mouth upon the neck of the bladder. The sides of the uterus retained their connexion with the pelvis, through the medium of the broad ligaments which were put moderately on the stretch. Under these circumstances the rest of the operation was easily completed by a narrow bistoury; the broad ligaments were cut through, and, great care being taken to avoid the uterus, the diseased mass was dissected away from the neck of the bladder, which was drawn down almost within sight. The operation was facilitated by previous child-bearing, although, notwithstanding the discharge, there was little tendency to prolapsus uteri. Though the womb had bled so freely before the operation, owing to the weakness of the circulation and other causes, yet not more than four or five ounces of blood were effused during its progress, the greater part coming away when the diseased structure was detached from the bladder and vagina in front. The pain was not greater than that of an instrumental delivery, nor perhaps so great, nor did the patient require to be at all confined. The principal suffering was experienced when the vagina was divided behind, and when it was dilated by the introduction of the hand. There was no decided collapse when the peritonæum was first laid open, the intestines approached the aperture, but did not protrude; after the operation the sides of the vagina collapsed, and the aperture above seemed to be covered by a retroversion of the bladder. An indurated portion of the left side of the vagina, as large as the first joint of the little finger, was separately detached by the knife after the completion of the rest of the operation. The pulse was distinct enough in the wrist during the greater part of the time; but when the diseased portions had been completely removed, on the occurrence of the hæmorrhage before mentioned, the beat of the radial artery was lost for about five minutes, the respiration being very feeble, and the patient lying, as after large floodings, very quiet. When brought to greater perfection, this method of operation will probably not occupy many minutes; but in this instance, that it might be done more safely, it was performed very slowly, and, like some deliveries by the forceps, it required more than an hour for its completion. It was not necessary in this case to vary the posture, the horizontal position being maintained throughout. The first incision was made at four o'clock, and the extirpation was finished by a quarter past five. Two ounces of gin and water were given during the operation, and the same quantity after its termination, with sixty drops of the tincture of opium. Previously to the operation the pulse was 120, tongue clean and rather white, and her manner composed; during its continuance, and when at the height of agitation, it rose to 140 in the minute, when she became faint, and approached nearly to a state of asphyxia. Two hours subsequently to the operation she was lying comfortably as if asleep, the whole body was warm, the pulse ninety-two and distinct, and the manner and countenance encouraging. On the third day there was great agitation and vomiting, and the pulse 112, without any obvious cause. Considerable solicitude was now entertained respecting her; but, happily, every uncomfortable symptom disappeared when the bowels were freely relieved. For ten days there was a reddish-brown discharge, and then for eight or nine more days it assumed a muco-purulent character, the flow from the vagina ceasing in a great measure on the nineteenth, and altogether on the twenty-first day. Shooting pain was more or less felt during the first three weeks after the removal of the uterus, on the left side, especially where the crural nerve is crossing the brim of the pelvis, under Poupart's ligament.

She is now, at the expiration of nearly six weeks, perfectly well.

375. *Of puerperal mania and phrenitis.*—All women, in the puerperal state, are more irritable, and more easily affected, both in body and mind, than at other times, and some even become delirious. The period at which this mental disease appears is various, but it is seldom if ever sooner than the third day, often not for a fortnight, and in some cases not for several weeks after delivery. It usually appears rather suddenly; the patient awakening, perhaps, terrified from a slumber, or it seems to be excited by some casual alarm. She is sometimes extremely voluble, talking incessantly, and generally about one subject, supposing, for example, that her child is killed, or stolen; or, although naturally of a religious disposition, she may utter volleys of oaths with great rapidity. In other cases she is less talkative, but is anxious to rise and go abroad. It is not, indeed, possible to describe the different varieties of incoherence, but there is oftener a tendency to raving than melancholy. She always recognises surrounding objects, and either answers any question put to her, or becomes more exasperated by it. She can by dint of perseverance, or by proper management, be for a time interrupted in her madness, or rendered in some degree obedient. In some instances she reasons for a little pretty correctly on her insane idea. The eye has a troubled appearance, the pulse, when there is much nervous irritation, or bodily exertion, is frequent, but it is not in general permanently so, though it is liable to accelerations; the skin is sometimes rather hot, the tongue white; the secretion of milk is often, but not always diminished; and the bowels are usually costive. There is seldom permanent headach; but this symptom is sometimes produced pretty severely by attempts to go to stool, if accompanied by tenesmus, or by efforts to void urine in strangury. In some instances the patient recovers in a few hours, in others the mania remains for several weeks, or even some months; but I believe it never becomes permanent, nor does it prove fatal unless dependent on phrenitis. Venesection has been advised in this disease; but I agree with those who consider it as hurtful, or at least as useless. The best practice, I think, is to apply leeches to the temples, open the bowels with a smart dose of calomel, keep the surface gently moist by means of saline julap, and afterwards allay irritation with liberal doses of camphor. Blisters have by some, for whose opinion I have much regard, been considered as useless, or detrimental; but I am confident I have seen them do good after they had discharged freely. Opium is a very doubtful remedy; it oftener makes the patient restless, than procures sleep; but in the wane of the disease it does in some cases agree with the patient, and is productive of great benefit. There is sometimes considerable difficulty in keeping the patient in bed, and making her take either food or medicine. It is therefore of great advantage to have early recourse to the strait waistcoat, which not only commands the patient, but tends to make her exercise self control. In the progress of the disease attention must be paid to the bowels, and it must be remembered that often the patient voids both urine and fæces without telling, not from being unable to retain them, but from inattention or perversity. The mind is not at first the subject of management, but, in the progress of the complaint, it may by prudent efforts be aided in convalescence by cheerful conversation, light reading, music, and afterwards by daily walking and change of scene.

376. Some are peculiarly liable to this disease after delivery, in consequence of the irritable state of the nervous system at that time. In such cases the patient must be carefully watched after parturition. Every irritation must be removed, every source of alarm or agitation obviated, and the camphorated julap with gentle laxatives will be proper remedies, these being the most powerful means of diminishing the excessive irritability of the nervous system. The diet is also to be regulated. If the patient do not sleep well hyoscyamus should be given. It is often of service to get the patient up as soon as can be done with safety, and have the mind occupied with such amusements and pursuits as keep it equally exercised, without risking irritation.

377. Melancholy usually comes on later than furious delirium. The disease differs nothing in appearance and symptoms from melancholy madness occurring at other times. It is obstinate; but generally goes off after the child is weaned, and the strength returns. It is therefore proper to remove the child, and send the patient to the country as soon as possible. In some instances both kinds of madness seem to be dependent on a morbid irritation, such as inflammation of the mamma, &c. Here our attention must be directed to the cause.

378. Inflammation of the brain usually appears still earlier than delirium from irritation. It may be caused by determination of blood to the head, or preternatural irritability of the sensorium, or may occur in consequence of a constitutional tendency to mania. It must be distinguished from puerperal delirium which is seldom dangerous, whilst this is a most fatal disease. It generally appears within the third day after parturition, but it may also take place later. The pulse usually continues frequent from the time of delivery. The patient does not sleep soundly, and indeed is watchful. She soon complains of throbbing within the head, or in the throat, or ears; then of confusion, hears acutely, dislikes the light, and speaks in a hurried manner, and often is unusually interested about some trifle. Then all at once furious delirium comes on. She talks rapidly and vociferously, the eyes move rapidly, are wild and sparkling, and very sensible to the light. This state may continue, with little interruption, till symptoms of compression appear, or there may be a short interval of reason, but presently the furor returns, and alternates perhaps with sullenness. The case is in these respects modified according to the inflammation; for sometimes it comes on rapidly and to a great extent, at other times it proceeds more slowly. The lochia are not suppressed, nor are the bowels bound, but the secretion of milk ceases. In three or four days she becomes paralytic in one side, and then sinks into a low comatose

state; the extremities become cold, the breathing laborious, and sometimes convulsions precede death. This disease requires the prompt and early use of the antiphlogistic treatment, general and local blood-letting, the use of purgatives, and the application of a blister to the scalp. The inflammatory symptoms being subdued, the delirium abates, or goes off, by the use of remedies formerly pointed out.

379. *Of hysteralgia.*—By hysteralgia I understand uterine pain proceeding from spasm, and not from inflammation. This may occur soon after delivery, and is marked by severe pain in the back and lower belly, frequent feeble pulse, sickness, and faintness. This is sometimes accompanied with discharge, or succeeded by expulsion of a coagulum. It requires an opiate immediately. Another modification of this comes on later, but always within three or four days after delivery, and attacks in general very suddenly. Perhaps the patient has risen to have the bed made, becomes sick, or vomits, and is seized with violent pain in the lower part of the belly, or between the navel and pubis. There is no shivering, at least it is not a common attendant, and the pulse becomes very rapid, being sometimes above 120, the skin is hot, the lochia usually obstructed, and the uterine region somewhat painful on pressure. After some hours the severity abates, and presently, by proper means, the health is restored.

380. As the lochial discharge is usually obstructed, this obstruction has been considered as the cause of the pain and other symptoms; but it is merely an effect, and sometimes does not exist. The cause appears to consist in a deranged state of action in the uterus, which is productive of spasm of the uterine fibres, and sometimes of the intestines. This is more apt to occur after a severe or tedious, than after an easy labor; but it may occur in any case, especially if exposed to cold. The symptoms will vary a little in severity and in appearance, according as the uterus alone is affected, or as spasm of the bowels is combined with the uterine pain. It is distinguished from inflammation by the sudden nature of the attack, the absence of shivering in general, the pain becoming speedily more severe than it does at the same period of inflammation; and frequently it greatly remits, or goes almost entirely away for a short time, It is possible, however, for this state, especially if it be neglected, to excite inflammation, which is marked by constant pain, more or less severe according to the part affected, and an obstinate continuance of the fever.

381. The first thing to be done is to administer a turpentine clyster to open the bowels. Then the belly is to be fomented, and, if speedy relief be not obtained by these means, an anodyne injection is to be given, and the saline julap is to be taken freely, with the addition of a little antimonial wine, in order to excite a free perspiration. If the symptoms continue, I strongly advise the detraction of blood. Purgatives are useful, and a blister must be applied to the pained part of the belly to prevent inflammation.

382. *Of diarrhœa.* If the patient have been costive before delivery, large masses of fæces may come down afterwards, producing violent pains in the belly, piles, tenesmus, or uterine hæmorrhage; or the same cause may excite diarrhœa with the passage of scybalæ. Both states require the use of gentle laxatives. Diarrhœa may also occur without previous costiveness; the stools are then fœtid or bilious. In this case the diet is to be strictly regulated; gentle laxatives are to be first given to evacuate the offensive matter, and then opiates are to be immediately resorted to. If neglected, great weakness, uterine hæmorrhage, or other serious consequences may be produced. When it is accompanied with bilious vomiting, and cramps or spasms, opiates are the principal remedy, and these must, if vomited, be given in the form of clysters.

383. *Of the signs that a woman has been recently delivered.*—We discover that a woman has been recently delivered, by finding that the external parts are relaxed, and redder, or of a darker color than usual. There is a sanguineous or lochial discharge. The uterus is enlarged, and has neither the shape of the gravid or unimpregnated uterus; the cervix is indistinct, and the os uteri is nearly circular, and will admit two or more fingers. The abdomen is prominent, and the integuments relaxed, wrinkled, and covered with light-colored broken streaks. The breasts are enlarged, have the areola very distinct, and contain milk; but it is possible for this secretion to take place independently of pregnancy. By examination per vaginam, within a fortnight or three weeks after delivery, the uterus may still be felt larger than usual, its lips softer, and capable of admitting the point of the finger without much difficulty. The milk at this period will not have left the breasts, which are firm, and have a dark areola round the nipple. Very contradictory accounts have been given by anatomists, of the appearance and size of the uterus, when inspected at different periods, after delivery. If the woman die of hæmorrhage, or from any cause destroying her, soon after delivery, the uterus is found like a large flattened pouch, from nine to twelve inches long. The cavity contains coagula or a bloody fluid, and its surface is covered with remains of the decidua. Often the marks of the attachment of the placenta are very visible. This part is of a dark color, so that the uterus is thought to be gangrenous, by those who are not aware of the circumstance. The surface being cleaned, the sound substance of the womb is seen. The vessels are extremely large and numerous. The fallopian tubes, round ligaments, and surface of the ovaria, are so vascular, that they have a purple color. The spot where the ovum escaped is more vascular than the rest of the ovarian surface. This state of the uterine appendages continues until the womb has returned to its unimpregnated state. It is a month at least, before the uterus return to its unimpregnated state, but the os uteri rarely, if ever, closes to the same degree as in the virgin state. We know that the woman has had a recent miscarriage, by the state of the breasts, the sanguineous discharge from the vagina, the size of the uterus, and the softness and dilatation of its mouth. If the woman die, the womb is found enlarged, its inner surface

covered with the decidua, or maternal portion of the placenta. The vessels are enlarged, the tubes and ligaments very vascular; the calyx of the ovum is bloody. This, at a more advanced period, forms a kind of cicatrix, or a dusky yellowish body, called corpus luteum. This mark may exist, although the woman have not borne a child, for the ovum may be blighted, perhaps even in the ovarium. It has been conjectured by some, that it may be produced even without sexual intercourse, but this point cannot be determined. It is supposed, however, that in such cases, the marks are not real corpora lutea; they have not ever been injected.

INDEX.

As the numbers are not prefixed to the paragraphs in the first part of the article, we have indicated some of the particulars pointed out in the following index by the page, and have then placed p. before the number.

MIEL (John), or Giovanni della Vite, a most eminent painter born in Flanders in 1599. He was a disciple of Gerard Seghers, and afterwards visited Italy to improve his style. At Rome he studied the works of the Caracci and Corregio; and was admitted into the academy of Andrea Sacchi. But he preferred the style of Bamboccio, whom he equalled. His general subjects were hunting, carnivals, gypsies, beggars, and pastoral scenes. But his easel pictures are his finest performances. He also painted historical pieces in a large size in fresco, and in oil. His pictures of hunts are particularly admired; the figures and animals being designed with uncommon spirit and truth. The transparence of his coloring, and the clear tints of his skies, enliven his compositions. His merit recommended him to Charles Emmanuel duke of Savoy, who invited him to his court, appointed him his principal painter, honored him with the order of St. Mauritius, and gave him a cross set with diamonds of great value. He died in 1664.

MIEN, *n. s.* Fr. *mine;* there is also a Dan. and Swed *mene;* Isl. *mena.* Look; countenance; behaviour; manner.

In her alóne that owns this book is seen
Clorinda's spirit, and her lofty *mien.* *Waller.*

What can have more the figure and *mien* of a ruin than craggs, rocks, and cliffs? *Burnet.*

She asked the reason of his woe;
She asked, but with an air and *mien*
That made it easily foreseen
She feared too much to know. *Prior.*

What winning graces, what majestic *mien!*
She moves a goddess, and she looks a queen. *Pope.*

Yours is, she said, the nobler hue,
And yours the statelier *mien!*
And, till a third surpasses you,
Let each be deemed a queen. *Cowper.*

Hail, Innocence! whose bosom all serene,
Feels not fierce passion's raving tempest roll!
Oh ne'er may Care distract that placid *mien!*
Oh ne'er may Doubt's dark shades o'erwhelm thy soul! *Beattie.*

With all that chilling mystery of *mien,*
And seeming gladness to remain unseen,
He had (if 'twere not nature's boon) an art
Of fixing memory on another's heart. *Byron.*

MIERIS (Francis), the Old, a justly celebrated painter, born in Leyden in 1635. He was at first placed under Abraham Toorne Vliet, and afterwards became a disciple of Gerrard Douw. He soon far surpassed all his companions. His pictures have been sold at vast sums. He painted silks, velvets, carpets, &c., in a peculiar manner. Portraits, conversations, musicians, patients attended by the doctor, chemists at work, mercers' shops, &c., are his usual subjects. It is his attention to minutiæ, united to breadth and truth, which give so much value to his works; which are very rare, and of course very costly. His own valuation of his time was a ducat an hour: and for one picture of a lady fainting, with a physician attending her, and applying remedies, he was paid at that ratio, so large a sum as 1500 florins. The grand duke of Tuscany is said to have offered 3000 for it, but was refused. Several of his pictures are still an ornament to the Florentine collection. One of them, a girl holding a candle, is accounted the most valuable. Houbraken mentions an incident in his life, which, as it tends much to his honor, may not be unacceptable to the reader. Mieris had conceived a real friendship for Jan Steen, and delighted in his company, though he was by no means so fond of drinking freely as Jan was accustomed to do every evening at the tavern. Notwithstanding this he often passed whole nights with his friend, in a joyous manner, and frequently returned very late to his lodgings. One evening, when it was very dark, and almost midnight, as Mieris strolled home from the tavern, he unluckily fell into the common sewer, which had been opened for the purpose of cleansing, and the workmen had left it unguarded. There he must have perished, if a cobbler and his wife, who worked in a neighbouring stall, had not heard his cries, and instantly run to his relief. Having extricated Mieris, they took all possible care of him; and procured the best refreshment in their power. The next morning, Mieris having thanked his preservers, took his leave; but particularly remarked the house, that he might know it another time. The poor people were totally ignorant of the person who had been relieved by them, but Mieris had too grateful a spirit to forget his benefactors, and, having painted a picture in his best manner, he brought it to the cobbler and his wife, telling them it was a present from the person whose life they had contributed to save; and desired them to carry it to his friend Cornelius Plaats, who would give them the full value for it. The woman, unacquainted with the real worth of the present, concluded she might receive a moderate gratuity for the picture; but her astonishment was inexpressible when she received the sum of 800 florins. He died in 1681.

Mieris (John), son of Francis, was born in Leyden in 1660, and learned the art of painting from his father. He travelled to Germany and thence to Florence, where his father's merit procured him an honorable reception from the grand duke, who wished to retain him in his service. But Mieris declined it, and proceeded to Rome, where his great abilities were well known, and his works much sought after. In that city he continued to work with great application, till an attack of the stone ended his days in 1690, when he was only thirty.

Mieris (William), called the Young Mieris, brother to John, was born in Leyden in 1662. During his father's life he made a remarkable progress; and after his death, by studying nature nearly equalled his father. He painted Rinaldo sleeping on Armida's lap, which sold at a high price. He also painted landscapes and animals with great truth; and he modelled in clay and wax in a very accurate manner. He is allowed to have been an artist of extraordinary merit. He died in 1747.

MIGDOL, or Magdol, in ancient geography, a place in the Lower Egypt, on this side Pihahiroth, or between it and the Red Sea, towards its extremity. The name denotes a tower or fortress It is probably the Magdolum of Herodotus, as the Septuagint render it by that name.

MIGHT. The preterite of may. See May.

MIGHT, *n. s.* } Sax. mıȝht, or maȝht; Goth. and Dan. *maght* (Goth. *meigu*, to have power). Strength; power; force: mighty is, strong; powerful; influential; hence valiant; great in number; vast; bulky; efficacious; excellent in any way; important: as an adverb, in low language, in a great degree: mightily and mightiness follow these senses.
MI'GHTY, *adj.* & *adv.*
MI'GHTILY, *adv.*
MI'GHTINESS, *n. s.*

Nimrod began to be a *mighty* one in the earth. *Genesis.*

They sank as lead in the *mighty* waters. *Exodus.*

Intreat the Lord, for it is enough, that there be no more *mighty* thunderings and hail. *Id.*

Woe to them that are *mighty* to drink wine. *Isaiah.*

If the *mighty* works which have been done in thee had been done in Sodom, it would have remained. *Matthew.*

Right so, quoth he, but he that never would,
Could never; will to *might* gives greatest aid. *Spenser.*

With whom ordinary means will prevail, surely the power of the word of God, even without the help of interpreters, in God's church worketh *mightily*, not unto their confirmation alone which are converted, but also to their conversion which are not. *Hooker.*

An oath of mickle *might*. *Shakspeare. Henry V.*

Do as adversaries do in law, strive *mightily*, but eat and drink as friends. *Shakspeare.*

There's ne'er a one of you but trusts a knave
That *mightily* deceives you. *Id.*
Think you see them great,
And followed with general throng and sweat
Of thousand friends; then, in a moment, see
How soon this *mightiness* meets misery. *Id.*

I'll sing of heroes and of kings,
In *mighty* numbers, *mighty* things. *Cowley.*
Wherefore should not strength and *might*
There fail, where virtue fails? *Milton's Paradise Lost.*
The Creator, calling forth by name
His *mighty* angels, gave them several charge. *Milton.*

Amazement seized
The rebel thrones, but greater rage to see
Thus foiled their *mightiest*. *Id.*
Giants of *mighty* bone and bold emprise. *Id.*
Lydiate excelled the *mighty* Scaliger and Selden. *Echard.*

With *might* and main they chaced the murderous fox,
With brazen trumpets and inflated box. *Dryden.*
Jove left the blissful realms above,
Such is the power of *mighty* love. *Id.*
The *mighty* master smiled. *Id.*

An ass and an ape conferring on grievances; the ass complained *mightily* for want of horns, and the ape for want of a tail. *L'Estrange.*

I was *mightily* pleased with a story applicable to this piece of philosophy. *Spectator.*

This privilege the clergy in England formerly contended for with all *might* and main. *Ayliffe.*

Lord of his new hypothesis he reigns;
He reigns: How long? Till some usurper rise,
And he too, *mighty* thoughtful, *mighty* wise:
Studies new lines. *Prior.*

These happening nearer home made so lasting impressions upon their minds, that the tradition of the old deluge was *mightily* obscured, and the circumstances of it interwoven and confounded with those of these later deluges. *Woodward.*

Thou fallest where many *mightier* have been slain. *Broome.*

The enemies of religion are but brass and iron, their mischiefs *mighty*, but their materials mean. *Delany.*

Linked with success, assumed and kept with skill,
That moulds another's weakness to its will;
Wields with their hands, but, still to these unknown,
Makes even their *mightiest* deeds appear his own. *Byron.*

MIGNARD (Nicholas), a very ingenious French painter, born at Troyes in 1628; but, settling at Avignon, he is generally styled Mignard of Avignon. He was afterwards employed at court, and became rector of the royal academy of painting at Paris. There were many of his historical pieces and portraits in the palace of the Thuilleries. He died in 1690.

MIGNARD (Peter), the brother of Nicholas, was born at Troyes in 1640; and acquired much of the taste of the Italian school. He had a superior genius to his brother. He painted popes Alexander VII. and Urban VIII., many of the Roman nobility, several Italian princes, and Louis XIV., who ennobled him, made him his principal painter, and appointed him director of the manufactories. Almost all the illustrious nobles of the French court followed the example of their sovereign, and were painted by Mignard. His style of execution in these portraits is wrought up with all the false taste and pompous parade which distinguished that period of the French nation; when parade passed current for true splendor; what was only specious or subtle, was received as useful and learned; and bombast assumed the station due only to true dignified simplicity. His pictures are all flutter; every thing seems in motion; even when the scene is laid in a close room, the draperies are flying about as in a high wind. The actions of his figures are in assumed airs; like pompous, and not unfrequently bad actors; and the coloring of his pictures, though fresh and vigorous, is not true, but teinted, and reminds the observer of the palette. With these defective points in his character, as an artist, Mignard is not unworthy of regard. His drawing is correct: his arrangement of parts is ingenious: and his invention fertile. He contrived to make his pictures ornamental, and is the best portrait painter of the French school. He died in 1695.

MIGNON, or MINJON (Abraham), a celebrated painter of flowers and still life, born at Frankfort in 1639. His father left him in very necessitous circumstances when only seven years of age. James Murel, a flower painter in that city, took him into his house, instructed him in his art till he was seventeen years old, and afterwards took him to Holland, where he placed him as a disciple with David De Heem, whose style Mignon imitated and adhered to; adding daily to his improvement by studying nature. He was well paid for his works. Weverman mentions one of a most capital kind, in which a cat has thrown down a pot of flowers that lie scattered on a marble table. It is so wonderfully natural that the spectator can hardly persuade himself that the water spilt from the vessel is not really running down from the marble. Mignon died in 1679, aged forty.

MIGNOT (Stephen), a member of the Academie des Inscriptions, France, was born in 1698, and graduated D. D. in 1722. He was the author of a variety of tracts, upon subjects connected with the discipline of the church of Rome. The principal are, A History of the Disputes between king Henry II. of England, and St. Thomas à Becket, 12mo.; On the Rights of the Monarch and the Civil Government over the Revenues of the Church, 6 vols.; A History of the Reception of the Council of Trent in the Catholic States, 2 vols.; The real History of the Church of St. Omer; A Paraphrase on the Psalms; and an elaborate treatise, Des prêts de Commerce, in five duodecimo volumes. He died in 1771.

MIGNOT (Vincent), a nephew of the celebrated Voltaire, was born at Paris in 1730, and obtained, without being a priest, several benefices, among which was the abbey of Sellieres. He became counsellor to the grand council, which place he resigned in 1765, reserving to himself the honorary title. In conjunction with the marquis de Ville-Vielle, he signed the profession of faith which Voltaire is said to have made just before his death; and transported the remains of that individual to the abbey of Sellieres, whence they were subsequently removed to the pantheon, or church of St. Genevieve, Paris. Mignot was the author of Histoire de l'Empire Ottoman, depuis son Origine jusqu'a la Paix de Belgrade, en 1740, Paris, 1771, 4 vols. 12mo., of which there is an English translation; Histoire de l'Imperatrice Irene, 1760 12mo.; Histoire de Jeanne I., Rein de Naples, 12mo.; Histoire des Rois Catholiques Ferdinand et Isabelle, 2 vols. 12mo.; and he translated Quintius Curtius, and Cicero de Senectute and de Amicitiâ. His death took place in 1790.

MI'GRATE, *v. a.*, MIGRA'TION, *n. s.*, MI'GRATORY, *adj.* } Lat. *migro*, *migratio*. To change residence or place of abode; to wander: migration, the act or habit of changing residence; removal.

Aristotle distinguisheth their times of generation, latitancy and *migration*, sanity and venation.
Browne's Vulgar Errours.

Although such alterations, transitions, *migrations* of the centre of gravity, and elevations of new islands, had actually happened, yet these shells could never have been reposed thereby in the manner we find them. *Woodward's Natural History.*

Besides the swallow, Mr. Pennant enumerates many other birds which *migrate* from Britain at different times of the year, and are then to be found in other countries; after which they again leave these countries, and return to Britain. The reason of these *migrations* he supposes to be a defect of food at certain seasons of the year, &c. *Dr. M. Good.*

MIGRATION OF BIRDS. It is generally believed that many different kinds of birds annually pass from one country to another, and spend the summer or winter where it is most agreeable to them; and that even the birds of our own island seek the most distant southern regions of Africa, when directed by a peculiar instinct to leave their own country. It has long been an opinion pretty generally received that swallows reside during winter in the warm southern regions; and Pennant enumerates many other birds which migrate from Britain at different times of the year, and are then to be found in other countries; after which they again leave these countries, and return to Britain. The reason of these migrations he supposes to be a defect of food at certain seasons of the year, or the want of a secure asylum from the persecution of man during the time of courtship, incubation, and nutrition. See ORNITHOLOGY.

MIGUEL (St.), or ST. MICHAEL, one of the principal and most fertile of the Azores. It appears to be entirely volcanic. A good account of it was published in the Philosophical Transactions, vol. lxviii. by Masson. 'The productions,' he says, 'differ greatly from those of Madeira. None of the trees of the latter are found in it except the saya. The mountains are covered with the erica vulgaris, and an elegant ever-green shrub very like a phyllyrea, which gives them a most beautiful appearance. It lies nearly east and west. Its length is about eighteen or twenty leagues; its breadth from two to five leagues, and its circumference sixty miles. It contains about 80,000 inhabitants, who carry on a considerable trade in corn, wine, and cattle. Its capital Ponta del Guda, or Punta del Guada, is situated on the south side of the island, on a fine fertile plain, and pretty regularly built; the streets are straight, and of a good breadth. It is supplied with good water, from mountains nine miles distant. The churches are elegant and well built. There is a large convent of Franciscan friars, another of those of St. Augustin, four convents for professed nuns, and three recolhimentos for young women and widows not professed. The vessels anchor in an open road, but it is not dangerous, as no wind can prevent their going to sea in case of stormy weather. The country around the city is plain for several miles, well cultivated, and laid out with good taste into spacious fields, which are sown with wheat, barley, Indian corn, pulse, flax, &c., and commonly produce annually two crops. The soil is remarkably easy to work, being mostly composed of pulverised pumice-stone. There are in the plains a number of pleasant country seats, with orchards of orange trees, esteemed the best in Europe. The second town is Ribeira Grande, on the north side of the island, containing a large convent of Franciscan friars, and one of nuns. The third town is Villa Franca, on the south side of the island, about eighteen miles east of the capital. It has a convent of Franciscan friars, and one of 300 nuns. About half a mile from the shore lies a small island called Ilhao, which is hollow in the middle, and contains a fine basin with only one entrance into it fit to hold fifty vessels secure from all weather. There are also several smaller towns viz. Alagoa, Agoa de Pao, Brelanha, Fanaes de Ajuda, and many hamlets. About twelve miles north-east of Villa Franca lies Furnas, a round deep valley, in the east part of the island, surrounded with high mountains, and about eighteen miles in circuit. The mountains are very steep, covered with beautiful ever-greens, and numberless rivulets run down their sides. The valley is well cultivated, and the fields are planted round with beautiful pyramidal poplars; which with a number of boiling fountains throwing up clouds

of steam, and a fine lake in the south-west part about six miles round, compose a prospect the finest that can be imagined. In the valley the roads are smooth and easy, there being no rocks but a fine pulverised pumice-stone. Of the numerous hot fountains in the valley, and on the sides of the mountains, the most remarkable is the Chaldeira, on a small eminence on the east by the side of a river, on which is a basin about thirty feet in diameter, where the water continually boils with prodigious fury. A few yards from it is a cavern in the side of the bank, in which the water boils in a dreadful manner, throwing out a thick, muddy, unctuous water several yards from its mouth with a hideous noise. In the middle of the river are several places where the water boils up so hot, that one cannot dip a finger into it without being scalded; along its banks are several apertures, out of which the steam rises to a considerable height, so hot that there is no approaching it; in other places one would think that a hundred smiths' bellows were blowing altogether, and sulphureous steams issuing out in thousands of places. Native sulphur is found in every chink, and the ground covered with it like hoar-frost. Near these boiling fountains are several mineral springs; two in particular whose waters have a very strong quality, of an acid and bitterish taste. About half a mile to the west, and close by the river, are several hot springs; and on the side of a hill west of St. Ann's Church are many others, with three bathing-houses. These waters are very warm, although not boiling hot; but at the same place issue several streams of cold mineral water, by which they are tempered, according to every one's liking. About a mile south of this place, and over a low ridge of hills, lies a fine lake about six miles in circumference, and very deep, the water thick, and of a greenish color. At the north end is a plain, where the sulphureous steams issue out in many places, with a surprising blowing noise. This lake seems to have no visible outlet. The other springs form a considerable river, called Quente, which runs about eight or nine miles through a deep rent in the mountains, and falls into the sea on the south side; near which are several places where the water boils up at some distance in the sea. This wonderful place had been little noticed until about thirty years ago, when some persons, afflicted with virulent disorders, tried its waters, and found immediate relief from them. Since that time it has been much frequented: several persons troubled with eruptions, and others who had lost the use of their limbs by the palsy, have been cured. A clergyman, a friar, and several gentlemen, afflicted with the gout, tried these waters, and were soon perfectly cured. The east and west parts of the island consist of high mountains, but the middle is low, interspersed with round conic hills, all of which have very recent marks of fire; the parts below the surface consisting of melted lava lying very hollow. Most of the mountains on the west have their tops hollowed out like a punch-bowl, and contain water. Near the west end is an immense deep valley, called Sete Cidades, surrounded with very abrupt mountains, about twenty-four miles round; in the bottom is a deep lake about nine miles in circuit, frequented by many water-fowls. All these mountains are composed of a white crumbly pumice-stone. This island was almost destroyed in 1638 by an earthquake, which continued eight days from the 26th of June. It lies in long. 22° 45′ W., lat. 38° 10′ N.

MIHIEL (St.), a little town of the department of the Meuse, France; the chief place of a canton in the arrondissement of Commercy. It has an inferior court for the arrondissement, and a court of assize for the department, a commercial college, and a post-office.

This town is situated in a pleasant valley on the right bank of the Meuse. In ancient times it was fortified, and endured several sieges at different periods, especially in 1635, when Louis XIII. attacked it in person, and narrowly escaped being killed before it; on this he caused its fortifications to be levelled with the ground. The inhabitants are manufacturers of cotton-cloths, woollen-drapery, and edge tools; they have also hydraulic cotton-spinning factories, forges, and tan-yards, and carry on a trade in corn, wine, wood, rape seed, table-linen, lace, paper, &c. In the parish church there is a beautiful monument of sculpture, worthy to fix the attention of all lovers of the fine arts. It is known by the name of the Sepulchre, and represents the tomb of Jesus Christ; it is made out of a single stone, of the production of the country, which for whiteness and fineness of grain almost equals marble. It is beautifully executed by Ligier Michier, a pupil of the celebrated Michael Angelo. Population 5200. This town is twelve miles north of Commercy, and twenty-four north-east of Bar-le-Duc. E. long. from Paris 3°, N. lat. 48° 56′.

MILAN, a late duchy of Italy, now included in the Austrian possessions of that peninsula, was bounded by the duchy of Savoy, the principality of Piedmont, and duchy of Montserrat, on the west; by Switzerland on the north; by the late Venetian territories, the duchies of Mantua, Parma, and Placentia, on the east; and by the Appennines and the Genoese territories on the south; extending about 100 miles from north to south, and 108 from east to west. It is esteemed one of the finest provinces in Italy, being watered by the Tessino, Sesia, Adda, Po, Oglio, Lambro, and other rivers, as well as by several canals and lakes; particularly lakes Como, Garda, Lugano, and Maggiore, which see. The whole of the Milanese, divided into four departments, was lately comprised in the Cisalpine republic; then in the kingdom of Italy: but on the reinstatement of the old order of things, in 1814, the part belonging to the king of Sardinia was restored, and the remainder incorporated with the Austrian, or Lombardo-Venetian kingdom of Italy. It there forms, along with the duchy of Mantua and the Valteline, the government of Milan, or more western of the two great divisions of Austrian Italy. Its extent is about 7700 superficial square miles, and its population 2,083,000. It is divided into the nine delegations of Milan, Pavia, Lodi, Como, Cremona, Sondrio, Bergamo, Brescia, and Mantua. Of these, that of Milan contains 670 square miles, and 427,000 inhabi

tants. The Sardinian, situated to the west of the Austrian Milanese, or government of Milan, and separated from it by the Ticino, a large river flowing from north to south, contains about 3300 square miles, and 556,000 souls, who inhabit eight large and 689 market-towns and villages. It is divided into the provinces or districts of Alessandria, Lumellina, Tortona, Voghera, Bobbio, Siccomario, Vigevanasco, Novara, and Sesia. See ITALY, AUSTRIAN.

Anciently this duchy, containing the north part of the old Liguria, was called Insubria, from its inhabitants the Insubres, who were conquered by the Romans, as these were by the Goths; who in their turn were subdued by the Lombards. See our article ITALY. Didier, the last king of the Lombards, was taken prisoner by Charlemagne, who put an end to the Longobardic empire, and appointed governors of Milan. These governors, being at a distance from their masters, soon began to assume an independency, which brought a dreadful calamity on the country; for, in 1152 the capital itself was levelled with the ground by the emperor Frederic Barbarossa, who committed great devastations throughout the duchy. Under this emperor flourished Galvian, a nobleman, descended from Otho, a Milanese. Galvian served with William prince of Montserrat, in the crusade, when Godfrey of Bouillon took Jerusalem: he killed in single combat the Saracen general, whom he stripped of his helmet, which was adorned with the image of a serpent swallowing a youth; and this ever afterwards was the badge of that family. His grandson Galvian, having opposed the emperor, was taken prisoner, and carried in irons into Germany, whence he escaped, and, returning to Milan, died in the service of his country. From him descended another Otho, at the time that Otho IV. was emperor, and who, being educated under cardinal Octavian Ubaldina at Rome, soon distinguished himself by his accomplishments.

In the mean time, Torriano, a nobleman of unbounded ambition, attempted to make himself master of Milan. The popular faction had for some time been caballing against the nobility; and this chief, putting himself at their head, expelled the bishop, and put to death or banished all the nobility: by which means the popular government was fully established; but Torriano ruled every thing. He was, however, soon opposed by Francis Sepri, who formed a party to deliver the city from his tyranny. But, while these parties were collecting their forces, cardinal Ubaldini was projecting the destruction of both, by means of his favorite Otho, whom he appointed archbishop of Milan; which was confirmed by pope Urban IV. The nobility now began to gather strength. Otho had no sooner procured a show of an army than he advanced towards Lake Maggiore, and took Arona, a strong post near that lake: but Torriano, marching against him with all his troops, obliged him to abandon the place. This was followed by the destruction of the castles of Arona, Anghiari, and Brebia: soon after which Torriano died, and was succeeded by his brother Philip, who got himself elected prætor of Milan for ten years. During his life, however, the party of the nobility increased considerably under Otho. Philip died in 1265, with great reputation for courage and conduct.

His successor Napi rendered himself terrible to the nobility, many of whom he proscribed and put to death. He acted with such fury, against that unfortunate party, that pope Clement IV. interdicted Milan, and excommunicated Napi and all his party. On this Napi began to lose his popularity, and Otho kept up the spirit of his party, who chose for their general Squarcini Burri, a man of great courage, whose daughter was married to Matthew Visconti, afterwards called Matthew the Great. At the same time they renewed their confederacy with the marquis of Montserrat, who was son-in-law to the king of Spain. The nobility having collected an army, which was joined by 600 Spanish cavalry, and a body of foot, gained some advantages. But in the mean time, Napi, having gathered together a superior army, attacked Otho and Burri, whom he defeated. After this disaster Otho applied to the pope; and Napi invited the emperor Rodolph into Italy, who constituted Napi his governor and vicar-general in Lombardy, and sent him a body of German horse, the command o which was given to Cassoni, Napi's nephew.

The Milanese exiles, however, soon became formidable, and chose for their general Godfrey, count of Langusio, a noble Pavian, who, being rich and powerful, enlisted many German mercenaries, at whose head he marched towards the lake Maggiore. All the towns in that country opened their gates to him, through the interest of the Visconti family. Godfrey being defeated and taken prisoner, he and thirty-four nobles had their heads struck off. This defeat greatly affected Otho; but after several battles, with alternate success, Otho totally defeated and took prisoner Napi himself. After this victory Cassoni was obliged to abandon Milan, and Otho kept possession of it till 1295, when he died, aged eighty-seven. He was succeeded by Matthew Visconti above-mentioned; and Milan continued in subjection to that family without any remarkable occurrence till 1378, when, by the death of Galeatius or Galeazzo II., his brother Barnabas became sovereign of Milan. He was brave and active, but excessively profuse in his expenses, as his brother Galeazzo had also been; and, to procure money to supply his extravagancies, resorted to every kind of oppression.

Galeazzo had engaged in an enterprize against Bologna, and the siege of it was continued by Barnabas. It lasted nine years; and cost nearly £40,000,000 sterling. Both the brothers were excessively fond of building. Barnabas erected a bridge over the Adda, consisting of three stories; the lowest for chariots and heavy carriages, the middle for horses, and the uppermost for foot passengers. He built another bridge which was carried over houses. To accomplish these, and other expensive schemes, he became very tyrannical, and every day produced fresh instances of his rapacity and cruelty. He instituted a chamber of enquiry, for punishing all those who had for five years before been guilty of killing boars, or even of eating them. They

who could not redeem themselves by money were hanged, and above 100 wretches perished in that manner. Those who had any thing to lose were stripped of their substance, and obliged to labor at the public works. He obliged his subjects to maintain his hunting dogs, and each district was taxed a certain number. This tyranny rendered the public ripe for a revolution, which was accomplished by his nephew John Galeazzo. He affected a solitary, devout life, void of ambition; but in the mean time had spies at his uncle's court, who gave him information of all that passed. Under pretence of paying a vow, to visit the church of the blessed Virgin upon mount Varezzio, he led Barnabas and two of his sons to accompany him to a private place on the road, where he had soldiers placed to seize them; and the houses of those who had followed them were given up to be plundered. The booty in plate, money, and rich furniture, was immense. The ministers of Barnabas were put to death; the citadel fell into the hands of Galeazzo, who found in it an immense sum of money. Barnabas was carried prisoner to his castle of Tritici, where his mistress, Dominia Porra, shut herself up a voluntary prisoner with him, and remained with him as long as he lived, which was only seven months after his degradation.

John Galeazzo was the first who took the title of duke of Milan. He made war with the Florentines, took Pisa and Bologne, and defeated the emperor in 1401, so that he entertained hopes of becoming master of all Lombardy; but his designs were frustrated by death, in 1402, in his fifty-fifth year. After his decease the Milanese fell into the most violent distractions, so that the government could not be supported, even in peace, without an army of 20,000 foot and as many horse. In 1421, however, Philip duke of Milan became master of Genoa: but, though he gained great advantages in all parts of Italy, the different states still found means to counterbalance his successes, and prevent him from enslaving them: so that Milan never became the capital of any extensive government; and in 1437 Genoa revolted, never afterwards to be reduced. Philip died in 1448, and by his death the male line of the Visconti family was ended. The next lawful heir was Valentina his sister, who had married the duke of Orleans, son to Charles V. of France. By the contract, the lawful issue of that marriage were to succeed to the duchy of Milan, in failure of the heirs male of the Visconti family; but this succession was disputed by Sforza, who had married Philip's natural daughter, and who obtained possession of the duchy. Louis XII., however, afterwards put in his claim, as grandson to John Galeazzo. For some time he was successful; but the French behaved in such an insolent manner that they were driven out of the Milanese by Maximilian Sforza and the Swiss. The Swiss and Milanese were now in their turn expelled by Francis I., who obliged the Sforza family to relinquish the government for a pension of 30,000 ducats a-year. Francis Sforza, the son of Maximilian, however, being assisted by the emperor and the pope, regained the possession of the Milanese about 1521; and, in 1529, the French king, by the treaty of Cambray, gave up his claim on the duchy. The emperors of Germany, however, seem to have had the fairest title to the Milanese in right of their having been long sovereigns of Italy. On the death of Francis Sforza, therefore, in 1536, Charles V. declared the Milanese to be an imperial fief, and granted the investiture of it to his son Philip II., king of Spain. In his family it continued till 1706, when the French and Spaniards were driven out by the Imperialists, and the emperor again took possession of it. It was confirmed to his house by the treaty of Baden in 1714, by the quadruple alliance in 1718, and by the treaty of Aix-la-Chapelle in 1748. But in June 1796 this country was overrun by the French under Buonaparte, and became an easy conquest. In 1797 it was revolutionized, and formed into several departments, as the Cisalpine republic. In April 1799 it was again overrun and reduced by the Austrians and Russians under Suwarrow: but, upon Buonaparte's return from Egypt, in was in 1800 once more reduced by the French; erected into the department of Olona, 13th of May 1801, and included in the Italian republic in December 1801, then in the kingdom of Italy, and finally restored to Austria as we have intimated.

MILAN, or MILANO, a very considerable and populous city of Italy, the capital of the Austrian Lombardo-Venetian kingdom, is nearly circular in its form, and extends to a circumference of nearly ten miles on the small river Olona: that is, the outer wall is of this extent, but it includes numerous gardens and plantations.

The streets are generally irregular and narrow, but the modern parts are in better taste, and the private houses, without having many pretensions to elegance, are tolerably built, and from three to five stories in height. Sumptuous family mansions occasionally appear, as in Rome and Genoa. The great entrance into the city is from the north-west, by the esplanade or arena, in the middle of which stands the Gothic castle of the family of Visconti. This arena, called the Piazza di Castello, was ornamented by prince Eugene Beauharnois, when viceroy of Italy, with plantations, grass plots, and gravel walks, and converted into a spacious garden; but the most popular public walk is the Corso, and the adjacent gardens, on the eastern side of the city. The fortifications are not of any available strength.

The cathedral is considered one of the finest Gothic churches in Europe. It is of fine white marble, and though begun in the sixteenth century, ages have passed over it and left it incomplete; 'the immense sums lavished upon it by wealthy sinners,' says a late traveller, 'to forward its continuation, seem to have retarded the work, by extending its plan. St. Charles Borromeo (the citizen saint of Lombardy) did much towards its completion; but, on his death, two centuries succeeded without hastening the progress of the erection, and the foundation of Galeazzo still remained unfinished, when a usurper like himself, influenced by the same motives and gifted with the same energies, at once completed it. Buonaparte is said to have contem

plated this temple, on his first arrival at Milan, with unsatiated delight; and to him it owes the fabrication of two-thirds of its splendid façade, a considerable number of its 400 statues, which rather incrust than decorate it, and the perfect condition in which it now strikes the eye with wonder and admiration.

'As we first saw it,' continues lady Morgan, 'in the radiance of the mid-day sun, its masses of white and polished marble, wrought into such elegant filigree as is traced on Indian ivory by Hindoo fingers, its slim and delicate pinnacles, tipped with sculptured saints, light as 'e'er danced on the point of a needle, or rode on the beams of the sun,' it looked (all gigantic as it is) like some fairy fabric of virgin silver; and left the eye dazzled, and the imagination fascinated. Its exterior lustre was strikingly contrasted with its interior solemnity; and, as we drew back the folds of the heavy drapery which shades the entrance of this as of all Italian churches, nothing could be more impressive than that long solemn sweep of nave, whose deep perspective fades and mellows as it recedes from the eye, and is finally almost lost in distance and obscurity. Before the high altar stands the shrine of St. Charles Borromeo, with its circle of burning lamps; the spacious choir rises behind it. The lateral aisles with their massive columns of red granite, and votive chapels, the porphyry baptismal font, the marble pavement, were tinged with the brilliant hues which fell through the high-arched and richly painted windows. A procession of the chapter, with their archbishop at their head, was issuing from the choir, and disappeared through a lateral door leading to the sacristy. Another less splendid but more solemn procession came forth from a chapel, announced by the ringing of a bell, the glare of torches, and accompanied by a guard of soldiers with fixed bayonets; it was the sacrament, borne on a velvet cushion, and under a superb canopy—the viaticum of some dying sinner.' It is 490 feet long, 298 broad, and 260 high. The façade is magnificent, and the three other sides hardly inferior. The roof is covered with slabs of marble; and above the dome there rises an elegant tower or spire, in the shape of an obelisk. All parts of the building are crowded with elegant marble statues, said to amount, inside and out, to the number of 4000. Here is a subterranean chapel, containing the body of Charles Borromeo, enclosed in a shrine of rock crystal. Several of the other churches, though far inferior to the cathedral, are worth attention, chiefly for the statues and paintings of celebrated masters which decorate them. The church of Laurentius has a Roman colonade of the Corinthian order, in marble of Paros.

When the emperor Joseph began those ecclesiastical reforms which the late republican government attempted to complete, tne ecclesiastical buildings of Milan occupied more than one-third of the city. There are still abundantly enough for all the purposes of religious worship.

The hospitals and other charitable institutions amount in all to about thirty. The Ospedale Maggiore is an immense edifice, capable of containing 1200 patients. It has a revenue of 100,000 rix-dollars. The foundling hospital receives about 4000 children. A lazaretto, outside of the city, is also on a vast scale, but is opened only for epidemics. 'In the refectory, or hall of the convent of the Dominicans,' says Mr. Eustace, 'was, as is well known, the celebrated Last Supper by Leonardo da Vinci, supposed to be his masterpiece. The convent was suppressed; and the hall turned into a store-room of artillery; and the picture was used as a target for the French soldiers to fire at. The heads were their favorite marks; and that of our Saviour, in preference to the others.' Lady Morgan, however, wholly contradicts this story; she saw the picture after Mr. Eustace, and could not trace the marks of a single shot, though the whole was in a decayed and faded state. 'The first object that meets the eye, on approaching this fresco,' she says, 'is a door cut through the legs of the principal figure, and that the figure of our Saviour!' The history of this door is well known at Milan. The dishes served at the monks' table were found to cool in passing along the cloisters; and it was decreed by the chapter that a communication should be opened from the refectory to the kitchen, which stood behind the picture of Leonardo. Thus the Last Supper was destroyed, that the abbot's dinner might be served hot! This anecdote, which might so well have served as a pendant for the 'target of the French soldiers,' Mr. Eustace has not mentioned, though, if he visited the picture, this door could not possibly escape him.

The Brera, or palace of the arts and sciences, has been dignified of late with the name of a University, for the education of young nobles. Under the recent government of the kingdom of Italy it changed its name to the Institute. Its revenues were augmented, its building (unfinished at the Revolution) was completed by the present government, and it was solemnly opened for public instruction, and for the service of the arts and sciences. Its schools are numerous: those for painting in all its branches, architecture, anatomy as applied to the arts, perspective, &c., being directed by native artists of great merit and celebrity. The school of engraving, under the admirable Longhi, is one of the first in Italy. The observatory, raised by the Jesuits in 1766, after a plan of Boscovich, is filled with the most expensive astronomical instruments, purchased in France, Germany, and England; among others a fine telescope by Herschel: the corridors with models of machinery, of ships, and other objects connected with the marine, &c. &c. The upper portico of this fine building contains a magnificent gallery, into which all that could be obtained or purchased of the ancient school of Lombardy is elegantly arranged: and the public library, where to the books left by the Jesuits were added the library of Pertusati, a part of that of Haller, and a small collection left by the cardinal Durini, together with a portion of the books collected from the suppressed convents. A sum was also assigned by the government for the purchase of new and valuable works, which sum was never permitted to accumulate. A few medals, once preserved, or neglected at the mint, were given to this institution, and formed the basis of a collection, which under the direction

of Signore Cataneo, one of the most learned numismatists in Europe, has grown to an extent almost unrivalled even in Italy.

Milan owes to the cardinal Frederic Borromeo her great and deservedly celebrated public library, the Bibliotheca Ambrosiana. The libraries of the Benedictines formed the nucleus of this collection, which has gradually extended to its present importance. The treasures of the collection are the MSS. of Leonardo da Vinci, called Codice Atlantico, from the size of the volume. They consist of a number of loose leaves, which Leonardo covered with sketches, notes, mathematical figures, and problems. Another celebrated MS. of the Ambrosian library is a Virgil, said to have been copied by Petrarch, in which he has traced some marginal annotations, and some lines on the death of Laura.

The church and the theatre are two of the principal engines with which the little governments of Italy have sustained their power. After the Duomo, there is no public building in Milan so attended, and so prized, as the theatre of the Scala. The ideas of pleasure and of devotion may indeed be here mingled in a truly Catholic manner; for it was on the ruins of the ancient church of Santa Maria della Scala that in 1778 this splendid theatre was built. The exterior is very handsome. 'The corps d'edifice is faced with arcades, which shelter the company, in descending from their carriages, from the inclemencies of the weather. Above these a broad terrace with a balustrade leads to the ridotto, or gaming rooms, which are under the protection of the government. Below, a very insignificant vestibule leads to the lower boxes and pit, whence staircases conduct to the upper circles. This theatre, which is said to be larger than the Opera house of London, has six circles of boxes, and a most spacious and well-arranged pit. Each circle has forty-six boxes. The imperial box, in the centre, is a superb open apartment, occupying the place of three boxes, and extending through three tiers in height. It is resplendent with gilding, and is surmounted with the imperial crown and cross. The proscenium is decorated with Corinthian columns, and the vaulted roof is richly painted in compartments by Pirego. In that part of the proscenium where, in England, is placed the king's escutcheon, there is here, as in the other theatres of Italy, a clock, whose dial with its transparent figures revolves before a strong light, to indicate the time to all parts of the house. The drapery of the boxes is uniform and rich; and great magnificence is displayed in their interior decoration, in hangings of silk and velvet cushions, with chandeliers (lighted at pleasure), and for the most part a small adjoining apartment for supper or play. All belonging to this establishment, except the corps dramatique, shows how material an object it is both to the government and people.

This is the evening home of almost all ranks, the recreation of the tradesmen, the exchange of the merchant, the closet of the critic, and the rendezvous of the politician. 'There alone,' says lady Morgan, 'amidst the openest publicity, can privacy find an asylum against the intrusions of espionage. The box is sacred—none can intrude there but the intimate friends of the lady or her husband: and the numerous 'arie di sorbetti' (dull pass of music) call for no attention even from musical enthusiasm; while with their accompaniments they drown the whispered conversation, whatever may be its tendency. Besides those whom pleasure or business, the performance or the rendezvous, bring to the Scala, it is frequented by another class, which under the new order of things daily increases through Italy. Its ranks, once so numerous, were supplied by the cadets of noble families, or of those who, shackled by birth, without opulence to enjoy, or business to occupy, lounge through life in indolent listlessness. In the evening these gros garçons are seen stuffed in their grandmothers' calashes at the Corso; at night they take their places, at stated times, in the boxes of such female friends as are good-natured enough to receive them. They are sure to arrive the first, and take their solitary seat in darkness and in silence. With the first coup d'archet, they fall into probationary stupor, from which they are only aroused by the arrival of the mistress of the box; when having bowed profoundly to her cordial ciavo, and kissed reverentially her graciously extended hands, they relapse into a doze, that resembles baron Trenck's sleep; for it is disturbed every ten minutes by successive visitors, to each of whom they are obliged to give up in turn their place; until at last, reaching the door, they make a profound bow and retire, to sleep out the rest of the evening in the successive boxes to which they have by prescription the entrée.'

There are three or four smaller theatres: but that of Girolamo della Crena alone disputes the popularity of the Scala. This is so called from the name of the principal puppets, who is a very powerful rival of the veteran Policinello. Whatever piece is represented upon this stage, Girolamo is always the principal actor. His distinctive character is, that he speaks Piedmontese, and makes stupid mistakes to please the inhabitants of Milan, and to feed their municipal prejudices against their neighbours; exactly as the Milanese Menichino performs for the amusement of the rest of the north of Italy, and as honest Pat is travestied on the London stage to flatter the cockney prejudices of John Bull. This species of wit is, in general, of tolerably cheap production, and it does not belong to very kindly dispositions; nevertheless Girolamo is sufficiently facetious, and, if his jokes are offensive to national vanity, after all, he is but a puppet. In 'Zemire ed Azore' (the piece we saw performed) Girolamo was the servant of the old merchant who gets into the enchanted palace, and he exhibits the usual quota of timidity that belongs to the servant of low comedy. He always addresses the beast by the appellation of 'mostro gentile,' or 'gentleman monster;' and, though more of action lay in his right leg than was strictly necessary for the development of the plot, yet some of his poetic flights were very ludicrous. His invocation to gloomy night, which he pronounced to be 'dark as a tailor's conscience,' is a fair specimen of his excellence in the anti-climax.' The people of fashion, at Milan go once in the season to Girolamo, as, at

Paris, the same class go to the Ambigu and the Gaieté, and it is thought good fun, once in a way; but the people find Girolamo good fun every night in the year, and rarely desert him.' The piazza del Duomo, we are told, also nightly exhibits *puppet-shows*, and the steps of the cathedral are crowded with an audience who have not the means of paying for a box at Girolamo's little theatre.

Of the ancient fortresses of Milan two antique towers alone remain. It is supposed that the castle erected by Galeazzo Visconti was begun in the year 1358. This having been demolished, a second was built by John Galeazzo: but, that also exciting the jealousy of the republican citizens, it became a sacrifice to the liberty of the country. Francis Sforza erected, for the third time, a fortification to overawe the people of Milan. Of this latter edifice the two towers just mentioned are a remnant. The rest of the building was levelled by the French; and a modern barrack occupies the site of the ancient keep. The remainder of the space was dedicated, by the late Italian government, to the amusement of the people; and was laid out into regular walks and grass-plats, with rows of trees, under the direction of Canonica, an architect of celebrity. This really elegant promenade was, at the epoch of its formation, called, in the language of that day, Forum Buonaparte; at present it is known under the more orthodox appellation of Place du Chateau.

At the point where the grand road over the Simplon terminates in the city of Milan, at the end of this promenade, a superb triumphal arch was commenced in Buonaparte's time, after the design of the marquis Luigi Cagnola. It is a work which, for magnitude and beauty, is well worthy the greater work whose successful termination it celebrates. But it is completed to scarcely more than one-third of its intended height. At the restoration the work was suspended, and the arch remains, as it was left in 1814, surrounded by masses of marble, as they were drawn from Carrara, and blocks of granite torn from the acclivities of the Simplon.

The Corso della Porta Orientale is particularly striking. Several new palaces, standing upon the site of demolished convents and churches, rise on either side. The façades are chiefly of the Greek order, and contrast forcibly with the massive, monastic fronts of the old buildings which are usually of Spanish architecture. On the left of this beautiful Corso is the public garden, which was but just finished at the restoration. It is separated from the street by a range of granite pillars, with a cornice surmounted by antique vases; and a light iron-railing, decorated with armorial bearings. The garden is cut into irregular alleys, diversified with trees and glass-plats, and watered by a canal. The buildings are in good keeping: they consist of an amphitheatre, a carousel or large pavilion, and an edifice in the centre for the public amusements. This temple of pleasure was, a few years back, a convent of nuns of a rigid order; and, if the spirit of some old lady abbess still visits the haunts of her power or penance, it must, all spirit as it may be, be struck with wonder. A flight of stairs leads from this garden to a public walk, which has been made and planted upon the ramparts, from the Porta della Tenaglia to the Porta Romana, a very considerable extent. The Villa Reale, a residence of the viceroy, adjoins, and adds considerably to the magnificence of the scene.

Lady Morgan notices, with enthusiasm, the Royal and Imperial Pensionat, a superb female seminary, founded by the late government. 'There, however,' she says, 'tameness and gentility, conventional grace and arbitrary elegance, were the prevailing characteristics. Of all the benefits which the revolution has conferred upon Italy, the greatest, the most permanent, is the new and liberal system of female education, raised upon the ruins of that demoralising bigotry which was calculated to make women concubines and devotees, but which could not produce good wives and good mothers. In most of the great capitals Buonaparte, or the Italian governments that acted under his influence, have formed establishments for the education of girls of all ranks, and endowed them with sufficient revenues; being fully aware how powerfully women contribute in determining the character of society; and how much a generation of well-educated females must contribute to raise it from that gulf of immorality into which the vices and feebleness of the old governments had plunged this part of Europe. The church, convent, and grounds of San Filippo Neri, belonging to an order of nuns, with a considerable revenue, were appropriated by the government to this establishment, intended as a national school for females, and more particularly for the orphan daughters of the officers of the army who fell in the service. It is a fact that, when this seminary was established, no Italian lady, fitted by education or experience, could be found, who was willing to accept the place of its directress; and the baroness de Lor, a lady of distinguished talent and irreproachable conduct, was taken from a similar establishment near Paris, to superintend the foundation at Milan.

'In our visit to this seminary we were accompanied by Madame de Lor herself; a lady whose society we afterwards sought upon all occasions with pleasure, and enjoyed with profit. As there is no English school of this description, no comparison can be drawn; but in the great points of air, space, elegance, and accommodation, neatness, freshness, and good order, it is impossible that it should be exceeded. The convent of St. Philip Neri resembles a royal palace: its arcades below, and its open galleries above, surround a beautiful and well cultivated garden. The dormitories are spacious, and provided with dressing-rooms abundantly supplied with water in superb fountains. There are also warmed apartments (scaldatorj), in which the children are permitted to amuse themselves before they retire to rest. The rooms are lighted at night by pending lamps, which are enclosed in glass bells, and burn till day-light, no candles being allowed. The hospital bed-rooms are on the upper story, and are attended by two nuns, sœurs de la charité: there are warm and cold baths adjoining. The wardrobe is a vast apart-

ment, filled with every article of female dress, made by the children themselves for their own use; the materials being found by the establishment. Another room is appropriated to works of ornament. There are also separate apartments for each class, all opening into the garden; by which the disadvantage of a close and heated atmosphere, so common even in our own best schools, is effectually avoided. We saw groups of little children hurrying from one class to another through blooming shrubs and orange trees, each with her little straw bonnet and basket on her arm. We afterwards saw them assembled in a vast and handsome hall, from whence they proceeded to an excellent dinner. When Madame de Lor entered several of the little ones clung around her, and each had her nom de caresse, or some mark of affection and familiarity. She addressed them all in French, to show us the progress they had made, and made them laugh heartily at their own mistakes. Italian is much cultivated; Milanese is rarely allowed. Their studies are liberal, and must shock many of their noble grandmothers, who scarcely learned to read and write; and who see their illustrious descendants (condemned by their birth to worthlessness and indolence) thus occupied in cutting out shifts, making stays, inventing dresses, and mending stockings, conversant in all the details of which no mother or mistress of a family should be ignorant, and combining these homely duties with languages, the arts, the sciences, and literature!'

As lately as 1743 a French traveller describes the archbishop's palace and the governor's house of Milan as the only residences in the city where the windows were completely glazed. Glass was then quite a distinction, as it still is in the villages about Rome and Naples; and some of the handsomest edifices in Lombardy had their windows covered with oiled paper. Glazing is now, however, general: though, amidst many great and beneficial changes introduced into Milan, much remains to be done: while the higher arts, for instance, have been well attended to, the art by which a door is hinged, or a window closed, is still in its infancy.

The trade of this city is not extensive, being chiefly confined to the import of its manufactory, consisting of silk stuffs, ribands, printed cottons, leather, paper, earthenware, and most beautiful porcelain. There is a considerable manufacture of tobacco and snuff also carried on on account of government. The carrying trade is favored by the two canals which connect it with the Adda on the one side, and the Ticino on the other.

Since 1800 the population of Milan has been in a state of progression. In 1805 it was estimated at 120,000; in 1806 at 125,000; in 1808 at 129,000; and in 1820 at 140,000. It is seventy-five miles E. N. E. of Turin; 145 north-west of Florence; and 280 north-west by north of Rome.

MILBORN PORT, a post town of Somersetshire, seated on a branch of the Parrat, 117 miles from London. It formerly sent two representatives to parliament, but is neither a market-town nor a corporation; but it appears in Domesday book to have once had a market, and fifty-six burgesses. It is surrounded by Dorsetshire. Here are nine capital burgesses, who yearly choose two bailiffs, that have the government of the borough under them, and jointly returned members to parliament with the two stewards, who are chosen yearly out of nine commonalty stewards, and have the custody of the corporation seal. These two stewards also distribute the profits of the lands given to the poor here, of which the commonalty stewards are trustees. There are two fairs, June 6th and October 28th. This ancient borough was disfranchised by the Reform Bill.

MILBOURNE (Luke), was the son of a nonjuring divine of that name, who was ejected from his living of Wroxhall in Warwickshire, where the subject of this article was born in 1667. He received his education at Pembroke Hall, Cambridge, when he took the degree of A. M., and, entering the church, obtained the rectory of St. Ethelburga, and the lectureship of St. Leonard's Shoreditch, London. He published Remarks on Dryden's Translation of the Æneis, which Johnson speaks of contemptuously. His name has also been introduced by Pope in the Dunciad. The remainder of his writings consist of a Version of the Psalms, and about thirty sermons. He died in 1720.

MILBURY, a post town of Worcester county, Massachusetts, six miles south of Worcester. This town has been formed of a part of Sutton since the last census, and is watered by Blackstone river. It contains a woollen manufactory, a saw mill, an iron manufactory, a rolling and slitting mill, a nail manufactory, six scythe shops, a gun manufactory employing forty or forty-five workmen, extensive tanneries, and paper and oil mills.

MILCH, *adj.* From MILK, which see. Yielding milk.

And then he blasts the tree, and takes the cattle
And makes *milch* kine yield blood. *Shakspeare.*

The best mixtures of water in ponds for cattle, to make them more *milch*, fatten, or keep them from murrain, may be chalk and nitre. *Bacon.*

Not above fifty-one have been starved, excepting infants at nurse, caused rather by carelessness and infirmity of the *milch* women. *Graunt.*

With the turnips they feed sheep, *milch*-cows, or fatting cattle. *Mortimer's Husbandry.*

MILD, *adj.*
MILD'LY, *adv.*
MILD'NESS, *n. s.*
} Sax. milꝺ; Goth. and Teut. *mild*; Swed. *milder*. Soft; tender; lenitive; not sharp or acrid: hence gentle; kind; tender; merciful; indulgent: the adverb and substantive corresponding.

Be not full of chidyng, but temporat, schewyng all *myldenesse* to all men. *Wiclif. Tyte.* iii.

This milky gentleness and course of yours;
You are much more at task for want of wisdom,
Than praised for harmful *mildness*. *Shakspeare.*

The execution of justice is committed to his judges, which is the severer part; but the *milder* part, which is mercy, is wholly left in the king.
Bacon's Advice to Villiers.

The air once heated maketh the flame burn more *mildly*, and so helpeth the continuance.
Id. Natural History.

The Irish were transplanted from the woods and mountains into the plains, that, like fruit trees, they

might grow the *milder*, and bear the better and sweeter fruit. *Davies.*

The rosy morn resigns her light,
And *milder* glory, to the noon. *Waller.*

Nothing reserved or sullen was to see,
But sweet regards, and pleasing sanctity;
Mild was his accent, and his actions free. *Dryden.*

Prince, too *mildly* reigning,
Cease thy sorrow and complaining. *Id.*

The same majestic *mildness* held its place;
Nor lost the monarch in his dying face. *Id.*

The folding gates diffused a silver light,
And with a *milder* gleam refreshed the sight. *Addison.*

His probity and *mildness* shows,
His care of friends and scorn of foes. *Id.*

Suppose your eyes sent equal rays
Upon two distant pots of ale,
Not knowing which was *mild* or stale. *Prior.*

It teaches us to adore him as a *mild* and merciful being, of infinite love to his creatures. *Rogers.*

Their qualities are changed by rendering them acrimonious or *mild*. *Arbuthnot on Aliments.*

Sylvia's like autumn ripe, yet *mild* as May,
More bright than noon, yet fresh as early day. *Pope.*

MILDEW, *n. s.* Sax. mıldeape; Teut. *millow*, i. ros *melleus*.—Minsheu. A disease or blight in plants, accompanied by a dewy moisture.

Here is your husband, like a *mildewed* ear,
Blasting his wholesome brother. *Shakspeare. Hamlet.*

The *mildew* cometh by closeness of air; and therefore in hills, or champaign grounds, it seldom cometh. *Bacon.*

Down fell the *mildew* of his sugared words. *Fairfax.*

Soon blasting *mildews* blackened all the grain. *Dryden.*

Morals snatch from Plutarch's tattered page,
A *mildewed* Bacon, or Stagyra's sage. *Gay's Trivia.*

Mildew is a disease of plants, caused by a dewy moisture which falls on them, and continuing, for want of the sun's heat to draw it up by its acrimony, corrodes, gnaws, and spoils the plant: or *mildew* is rather a concrete substance, which exudes through the pores of the leaves. *Hill.*

MILDEW, in agriculture, a disease frequently destructive to corn, pulse, and garden-crops. It is occasioned, says Hill, by a dewy moisture which falls on them, and continuing, for want of the sun's heat to draw it up, by its acrimony corrodes, and destroys the plant. Others say that mildew is a thick clammy vapor exhaled in the spring and summer from the plants, blossoms, and even the earth itself, in close, still weather, where there is neither sun nor wind. Miller thinks the true cause of the mildew appearing most upon plants which are exposed to the east, is a dry temperature in the air when the wind blows from that point, which stops the pores of the plants, and prevents their perspiration; whereby the juices of the plants are concreted upon the surface of their leaves, which, being of a sweetish nature, insects are enticed thereto. It sometimes rests on the leaves of trees in form of a fatty juice, and sometimes on the ears of corn. It is naturally very tough and viscous, and becomes still more so by the sun's heat exhaling its more fluid parts; by which means the young ears of corn are so daubed over, that they can never arrive at their full growth. Bearded wheat is less subject to the mildew than the common sort; and it is observed that newly dunged lands are most liable to mildew. The best remedy is a smart shower of rain, and immediately afterwards a brisk wind. If the mildew is seen before the sun has much power, it has been recommended to send two men into the field with a long cord, each holding one end; and, drawing this along the field through the ears, the dew will be dislodged from them before the heat of the sun is able to dry it to that viscous state in which it does the mischief. Some also say, that lands which have for many years been subject to mildews, have been cured of it by sowing soot along with the corn, or immediately after it. Mr. J. S. Sagar, the author of a treatise upon this subject, observes, that the mildew is of such a sharp corrosive nature, that it raises blisters on the feet of the shepherds who go barefoot, and even consumes the hoofs of the cattle. He considers the mildew as a principal cause of epidemical distempers among the cattle. The mildew producing these diseases, he says, is that which dries and burns the grass and leaves. It falls usually in the morning, particularly after a thunder-storm. Its poisonous quality (which does not continue above twenty-four hours) never operates but when it has been swallowed immediately after its falling. The disorder attacks the stomach, is accompanied with pimples on the tongue, loss of appetite, a desiccation of the aliments on the stomach, a cough, and difficulty of respiration. See RURAL ECONOMY.

MILE, *n. s.* } Fr. *mille*; Ital. *miglio*; Lat.
MILE'-STONE, } *mille* (a thousand paces). An English road measure of 1760 yards: milestone, the stone set to mark each mile.

We must measure twenty *miles* to-day. *Shakspeare.*

Within this three *mile* may you see it coming,
A moving grove. *Id. Macbeth.*

When the enemy appeared, the foot and artillery were four *miles* behind. *Clarendon.*

Millions of *miles*, so rapid is their race,
To cheer the earth they in few moments pass. *Blackmore.*

A MILE is a measure of length or distance containing eight furlongs. The English statute mile is eighty chains. Three miles make one league (see LEAGUE); but it varies in different countries. See WEIGHTS and MEASURES.

MILETUS, in ancient geography, a town of Crete, mentioned by Homer. It is said to be the mother town of Miletus in Caria, whither a colony was led by Sarpedon, the brother of Minos. Ephorus, quoted by Strabo.

MILETUS, in ancient geography, a celebrated town of Asia Minor, on the confines of Ionia and Caria. It was the capital city of Ionia, and famous both for the arts of war and peace. It was situated about ten stadia south of the mouth of the Mæander, near the sea-coast. It was founded by a Cretan colony under Miletus, the companion of Bacchus; or, according to others, by Nileus the son of Codrus; or by Sarpedon a son of Jupiter. It has successively been

called Lelegeis, Pithyusa, and Anactoria. The Milesii were very powerful, and long maintained an obstinate war against the kings of Lydia. They early applied themselves to navigation; and planted no less than eighty colonies, or, according to Seneca, 380, in different parts of the world. It was taken by Alexander with much difficulty. It gave birth to Thales, Anaximander, Anaximenes, and other great men. According to Virgil, it was noted for its excellent wool, and for a temple and oracle of Apollo Didymæus. In this town St. Paul preached his farewell sermon to the elders of Ephesus. See Acts xx. 18—35. It is now called by the Turks Melas.

MIL'FOIL, *n. s.* Lat. *millefolium.* Yarrow.

Milfoil and honey-suckles pound,
With these alluring savors strew the ground.
Dryden.

MILFOIL, or YARROW. See ACHILLEA.

MILFORD, a town of Hillsborough county, New Hampshire, on the Sowhegan; two miles south-west of Amherst, and forty-eight north-west of Boston. Population 1117. It is a pleasant town, and contains two cotton manufactories, and two houses of public worship, one for Congregationalists, and one for Baptists.

MILFORD HAVEN, one of the first harbours in Europe, and indisputably the best in Britain, is situated in Pembrokeshire in South Wales, and lies on the north side of the Bristol Channel. It is very large, safe, and deep; there is no danger of going in or out with the tide, or almost with any wind. If a ship comes in without a cable or anchor, she may run ashore on the ooze, and there lie safe till she is refitted; and in an hour she may get out of the harbour into the open sea. It is very convenient for ships bound from the English or Bristol Channels to Ireland, or farther west, and 1000 sail of any size may ride secure in it. It has sixteen deep and safe creeks, five bays, and thirteen roads. The spring tide rises thirty-six feet; so that ships may at any time be laid ashore. Dale harbour is a ready outlet for small vessels, where they may ride in two or three fathoms at low-water. In the reign of queen Elizabeth, before the Spanish invasion, two forts were begun at the entrance of Milford Haven, one on each side, called Nangle and Dale blockhouses; but they were not then finished.—The stack rock rises here above water, near the middle of the entrance between Nangle and Dale. Penermouth is the opening of that branch of the haven on which Pembroke is seated, and where the custom-house of Milford is kept. The breadth of the entrance between rock and rock is but 200 yards at high-water, and 112 at low-water. There is a ridge of rocky ground named Carrs, which runs almost across Milford Haven, from Peter church toward Llanstadwell, where it renders the landing-place difficult to strangers, from its not appearing at low water. As this harbour lies near the mouth of the Severn, a ship in eight or ten hours may be over on the coast of Ireland, or off the Land's End in the English Channel; and a vessel may get out hence to the west much sooner than from either Plymouth or Falmouth. This harbour has been greatly improved by new works, at the expense of government. The parliament in 1759 granted £10,000 for fortifying the harbour of Milford, all of which was expended on the fort of Neyland, which, however, still remains unfinished. A quay and several new buildings have lately been erected by a society of Quakers, who have established themselves here from America. It has a commodious custom-house at the lower end of the town, which is independent of that of Pembroke, but the trade of the port is at present inconsiderable. This place has lately been established as one of his majesty's principal dock-yards for ship-building.

MILHAU, a town of France, in the department of the Aveyron, on the Tarn. Its manufactures are of gloves, hats, and leather. Population 6100: twenty-seven miles south-west of Rhodez.

MILHAUD, or MILLAU, a very ancient town, the chief place of a sub-prefecture of the same name, in the department of the Aveyron in France, having an inferior court, a chamber of commerce, an agricultural society, and a communal college. It is a post-town, containing 6000 inhabitants. It stands in a fine valley on the right bank of the Tarn, a little below the spot where it joins the Gambie, and is surrounded by hills planted with peach and almond trees; the houses are well built; the streets, though narrow, are well ventilated, and adorned with several public fountains; there is also a very pretty square, and some pleasant walks. This town was known in the time of Julius Cæsar by the name of Æmilianum; it was once fortified, and became one of the strongest places in the possession of the Calvinists: Louis XIII. however, having carried it by assault in the year 1629, caused its fortifications to be demolished. Manufactures are carried on here of cloth, serge, gloves, and chamois, white and other leathers; the inhabitants also trade in wool (raw and spun), leather, building wood, staves, cheese, wine, almonds, cattle, &c. It is the native place of general Solignac; and is forty-two miles south-east of Rhodez, twenty-one north-east of St. Affrique, fifty-four south-west of Florac, and 456 S. S. E. of Paris.

MILIARENSIS, in antiquity, a silver coin of the empire, substituted by Constantine the Great in the room of the denarius; and so called because he fixed the price of the pound of gold at 1000 pieces of this new silver. But as he divided the pound of gold also into seventy-two solidi, each solidus really contained 13⅞ miliarenses, though it passed for fourteen; which difference between the real and current value of the solidus, in relation to the miliarenses, must have occasioned disputes in the payment of small sums. To remedy this inconvenience, it was thought proper to alter the weight of the silver money, and, having fixed the price of the pound of silver at five solidi, to coin sixty pieces out of it, which retained the name miliarenses, though the pound of gold was worth but 864. It does not appear how many miliarenses Constantine coined out of the pound of silver; but, if the piece of gold was nearly the same in his reign as when five solidi were worth a pound of silver, the pound must have been worth 14⅖ pounds

of silver; and 1000 divided by 14⅜ gives 69⅝ for the number of miliarenses coined out of the pound. Therefore it is probable that Constantine's number was either sixty-nine or seventy.

MIL'IARY, *adj.* Fr. *miliaire;* Lat. *milium* (millet). Small; resembling millet: applied medically to small eruptions.

The scarf-skin is composed of small scales, between which the excretory ducts of the *miliary* glands open. *Cheyne.*

MILIARY FEVER. See MIDWIFERY.

MILI'CE, *n. s.* Fr. *milice.* Standing force. A word, says Dr. Johnson, innovated by Temple, but unworthy of reception.

The two-and-twentieth of the prince's age is the time assigned by their constitutions for his entering upon the public charges of their *milice.* *Temple.*

MIL'ITANT, *adj.* Fr. *militante;* Lat. *militans.* Warlike; fighting; often applied to the spiritual warfare of the Christian church.

Against foul fiends they aid us *militant;*
They for us fight; they watch and duly ward,
And their bright squadrons round about us plant. *Spenser.*

Then are the public duties of religion best ordered, when the *militant* church doth resemble, by sensible means, that hidden dignity and glory wherewith the church triumphant in heaven is beautified. *Hooker.*

The state of a Christian in this world is frequently compared to a warfare: and this allusion has appeared so just, that the character of *militant* has obtained as the common distinction of that part of Christ's church sojourning here in this world, from that part of the family at rest. *Rogers.*

MIL'ITAR, *adj.* } Fr. *militaire;* Lat. *mili-*
MIL'ITARY. } *taris.* Warlike; engaged as a soldier; soldierly. Militar is now wholly out of use.

In the time of Severus and Antoninus, many, being soldiers, had been converted unto Christ, and notwithstanding continued still in the *military* course of life. *Hooker.*

He will maintain his argument as well as any *military* man in the world. *Shakspeare. Henry V.*

Although he were a prince in *militar* virtue approved, yet his cruelties weighed down his virtues. *Bacon's Henry VII.*

He was with general applause, and great cries of joy, in a kind of *militar* election or recognition, saluted king. *Bacon.*

Numbers numberless
The city gates out-poured, light-armed troops
In coats of mail and military pride. *Milton.*

The wreathes his grandsire knew to reap
By active toil, and *military* sweat,
Pining incline their sickly leaves. *Prior.*

MILITARY AFFAIRS. In the time of the Anglo-Saxons the military force of England was in the hands of the dukes or heretochs, who were constituted through every province and county in the kingdom; being chosen out of the principal nobility, and such as were most remarkable for being sapientes, fideles, et animosi. Their duty was to lead and regulate the English armies, with a very unlimited power; prout eis visum fuerit, ad honorem coronæ et utilitatem regni. And they were elected by the people in their full assembly, or folkmote, in the same manner as sheriffs were elected; following that old fundamental maxim of the Saxon constitution, that where any officer was entrusted with such power as, if abused, might tend to the oppression of the people, that power was delegated to him by the vote of the people themselves. The ancient Germans, the ancestors of the Saxons, had also their dukes, as well as kings, with an independent power over the military, as the kings had over the civil state. The dukes were elective, the kings hereditary, as appears from Tacitus. In electing their kings the blood-royal was regarded; in choosing their dukes or leaders warlike merit; as Cæsar relates of them, in his time, that whenever they went to war they elected leaders to command them. This large share of power thus conferred by the people, though intended to preserve the liberty of the subject, was detrimental to the prerogative of the crown; and Edric, duke of Mercia, in the reign of Edmund Ironside, who by his office of heretoch was entitled to a large command in the king's army, by his repeated treacheries at last transferred the crown to Canute the Dane. It is agreed by all historians that king Alfred first settled a national force in England, and by his prudent discipline made all his subjects soldiers: but we are uninformed as to the particulars of his celebrated regulation; though the dukes seem to have been left in possession of too large a power, which enabled duke Harold, on the death of Edward the Confessor, though not of the royal blood, to mount the throne in prejudice of Edgar Atheling the rightful heir. Upon the Norman conquest the feudal law was introduced in all its rigor, and all the lands in the kingdom were divided into above 60,000 knight's fees; and for every knight's fee a knight or soldier, miles, was bound to attend the king in his wars for forty days in a year; in which time, before war was reduced to a science, the campaign was generally finished, and a kingdom either conquered or victorious. By these means the king had, without expense, an army of 60,000 men always at his command. And accordingly we find a law of William I. which enjoins the personal attendance of all knights and others; quod habeant et teneant se semper in armis et equis, ut decet et oportet, &c. This personal service in time degenerated into pecuniary commutations or aids; and at last the military part of the feudal system was abolished at the restoration. In the meantime, however, the kingdom was not left without defence, in case of insurrections or invasions Besides those who by their military tenures were bound to perform forty days' service in the field. And now arose the coincidence between these tenures and our early militia laws; the progress of which will be given in the following article.

When the nation was engaged in war, more veteran troops and more regular discipline were esteemed necessary, than could be expected from a mere militia; and therefore at such times more rigorous methods were adopted for raising armies, and for the due regulation and discipline of the soldiery. Martial law, Sir M. Hale observes, which is built upon no settled principles, but is entirely arbitrary in its decisions, is in truth no law, but something indulged rather than allowed as a law. The necessity of order and discipline in an army is the only thing which can give it

countenance; and therefore it ought not to be permitted in time of peace, when the king's courts are open for all persons to receive justice according to the laws of the land. Wherefore, Thomas earl of Lancaster being convicted at Pontefract 15 Edw. II. by martial law, his attainder was reversed, 1 Edw. III., because it was done in time of peace. And it is laid down, that if a lieutenant, or other that hath commission of martial authority, doth in time of peace execute any man by color of martial law, this is murder; for it is against magna charta. The petition of right enacts that no soldier shall be quartered on the subject without his own consent; and that no commission shall issue to proceed within this land according to martial. And whereas, after the Restoration, king Charles II. kept up about 5000 regular troops, by his own authority, for guards and garrisons, which James II. by degrees increased to no less than 30,000, all paid from his own civil list; it was made one of the articles of the bill of rights that the raising or keeping a standing army within the kingdom in time of peace, unless with consent of parliament, is against law. But as the keeping of standing armies (first introduced by Charles VII. in France, 1445) has of late universally prevailed over Europe, it has also for many years past been annually judged necessary by our legislature, for the safety of the kingdom, and the defence of the possessions of the crown of Great Britain, to maintain in time of peace a standing body of troops, under the command of the crown; who are, however, ipso facto disbanded at the expiration of every year, unless continued by parliament. To keep this body of troops in order, an annual act of parliament passes, called the Mutiny Act, 'To punish mutiny and desertion, and for the better payment of the army and their quarters.' This regulates the manner in which they are to be dispersed among the several inn-keepers and victuallers throughout the kingdom: and establishes a law martial for their government. By this it is enacted that if any officer or soldier shall excite, or join any mutiny, or, knowing of it, shall not give notice to the commanding officer, or shall desert, or list in any other regiment, or sleep upon his post, or leave it before he is relieved, or hold correspondence with a rebel or enemy, or strike or use violence to his superior officer, or shall disobey his lawful commands; such offender shall suffer such punishment as a court-martial shall inflict, though it extend to death itself. However expedient the most strict regulations may be in time of actual war, yet, in times of profound peace, a little relaxation of military rigor would not be productive of much inconvenience. And, upon this principle, though, by our standing laws, desertion in time of war is felony without benefit of clergy, and the offence is triable by a jury, and before the judges of the common law, yet, by our militia laws, a much lighter punishment is inflicted for desertion in time of peace. But any of the faults above mentioned are, equally at all times, punishable with death itself, if a court martial shall think proper. This discretionary power of the court martial is indeed to be guided by the directions of the crown, which, with regard to military offences, has almost an absolute legislative power. 'His majesty,' says the act, 'may form articles of war and constitute courts-martial, with power to try any crime by such articles, and inflict such penalties as the articles direct.' A vast and most important trust! an unlimited power to create crimes, and to annex to them any punishment not extending to life or limb! These are indeed forbidden to be inflicted, except for crimes declared to be so punishable by this act. But as soldiers, by this annual act, are thus put in a worse condition than other subjects; so, by the humanity of our standing laws, they are in some cases put in a better. By stat. 43 Eliz. c. 3, a weekly allowance is to be raised in every county for the relief of soldiers that are sick, hurt, and maimed: besides the benefit of the royal hospital at Chelsea, for such as are worn out in their duty. Officers and soldiers, that have been in the king's service, are by several statutes entitled to use any trade or occupation they are fit for, in any town in the kingdom, except the two universities. And soldiers in actual military service may make nuncupative wills, and dispose of their goods, wages, and other personal chattels, without those forms, solemnities, and expenses, which the law requires in other cases. See War.

Military Exercise. See Exercise and Manual.

Military Manœuvres. The military manœuvres of our army might historically include all the triumphs of the British arms. But they are taken technically for the entire detail of the exercise and movements of the military body; and in this we understand very decided improvements are in agitation at the War Office. Our informant adds that the new book of Regulations may be expected to be issued monthly: we shall therefore refer the reader for a brief account of its contents, and a comparison of the ancient and modern manœuvres, to the article War.

Military Tenures. See Feudal System and Tenure.

Military Ways, viæ militares, are the large Roman roads which Agrippa procured to be made through the empire, in the time of Augustus, for the more convenient marching of troops and conveyance of carriages. N. Bergier has written the history of these military roads, which were paved from the gates of Rome to the extreme parts of the empire.

MILITES, adscriptitii, supernumerary, men that followed the Roman armies for the purpose of filling up any vacancies which might occur through death or sickness. No particular duties were exacted from them, except that of marching in front of the troops, in order to annoy the enemy with their cross-bows.

Milites Causarii, among the Romans, soldiers who were discharged on account of sickness, and inability to serve, or from some other cause.

Milites Consummati, soldiers among the Romans who had served their prescribed period. They were also called emeriti.

Milites Mercenarii, auxiliary troops, or soldiers, who were hired by the Romans in the

time of war. Hence men hired to fight are called mercenaries.

Milites Provinciales, troops which composed the Roman legions, and consisted wholly of Romish citizens. The auxiliary troops were originally drawn out of the Italian provinces, that were in alliance with Rome; and, when they afterwards became Roman citizens, soldiers were enlisted and paid from other countries. Thus, before Barbary fell under the Roman yoke, large levies were obtained from that quarter of the globe.

Milites Stationarii, bodies of armed men, among the Romans, who were distributed through the empire, in order to check disorders, prevent plunder, and so escort the guilty to the tribunals of justices.

Milites Subitarii, troops raised upon emergency, especially on the breaking out of unexpceted hostilities. On these occasions men of all ages were obliged to enrol themselves.

Milites Urbani, a class of Roman soldiers, or rather an armed portion of the inhabitants of Rome, which remained in the capital, without any particular mark of distinction among themselves, in order to protect it during the absence of the regular troops, on the sudden commencement of hostilities. During the reign of the emperors, these men became the janissaries of Rome, for they insensibly grew into so much importance that they yielded in rank and consideration, as a body, to the prætorian bands only. They had regular camps in the city, which were called castra urbana. They were in high favor with the emperors, and generally shared a large proportion of the legacies which were left by the former in their wills. The privates received half the pay and subsistence which were allowed the prætorian bands; enjoyed exclusive privileges, and could only be commanded by the prefect of Rome.

The French, in imitation of the Romans, have called the different bodies of armed men oelonging to the several towns and districts, troupes urbanes, urban troops.

MILIT'IA, *n. s.* Lat. *militia*. The trainbands; a standing military force.

Let any prince think soberly of his forces, except his *militia* be good and valiant soldiers. *Bacon.*

The *militia* was so settled by law, that a sudden army could be drawn together. *Clarendon.*

Unnumbered spirits round thee fly,
The light *militia* of the lower sky. *Pope.*

Thus nature's refuse, and the dregs of men,
Compose the black *militia* of the pen. *Young.*

The Militia, or standing national force of this country, is traced by most historians to king Alfred, who by his prudent discipline made all the subjects of his dominions soldiers.

The feudal military tenures soon became involved in this force: they were established for the purpose of protection, and sometimes of attack, against foreign enemies; while for the further defence, in cases of domestic insurrections or foreign invasions, various other plans have been adopted, all of them tending to unite the character of a citizen and soldier. The legal authorities thus class them:—First the assise of arms, enacted 27 H. II., aud afterwards the statute of Winchester, 13 Ed. I. c. 6, obliged every man, according to his state and degree, to provide a certain quantity of such arms as were then in use; and it was part of the duty of constables under the latter statute to see such arms provided. These weapons were changed by stats. 4 and 5, P. & M. c. 2, into more modern ones; but both these provisions were repealed by stats. 1 Jac. 1, c. 25; 21 Jac. 1, c. 28. It was now usual, from time to time, for our princes to issue commissions of array; the form of the commission was settled anno 5 Hen. IV., so as to prevent the insertion therein of any new penal clauses. Rushw. pt. 3, p. 662, 667. See 8 Rep. 375, &c. But it was also provided, by stats. 1 E. III. stat. 2, c. 5, 7, and 25 E. III. stat. 5, c. 8, that no man should be compelled to go out of the kingdom at any rate, nor out of his shire but in cases of urgent necessity; nor should provide soldiers unless by consent of parliament. We first find lord-lieutenants of counties mentioned as known officers in the stat. 4 and 5 P. & M. c. 3, though they had then not been long in use; for Camden speaks of them, in the time of queen Elizabeth, as extraordinary magistrates constituted in times of difficulty and danger. But the introduction of these commissions of lieutenancy, which contained in substance the same powers as the old commissions of array, caused the latter to fall into disuse. Thus things continued till the repeal of the statutes of armour in the reign of king James I.; after which, when king Charles I. had, during his northern expeditions, issued commissions of lieutenancy, and exerted some military powers which, having been long exercised, were thought to belong to the crown, it became a question in the long parliament how far the power of the militia did inherently reside in the king; being now unsupported by any statute, and founded only upon immemorial usage. This question, long agitated with great heat and resentment on both sides, became at length the immediate cause of the fatal rupture between the king and his parliament: the two houses not only denying this prerogative of the crown, the legality of which might perhaps be somewhat doubtful, but also seizing into their own hands the entire power of the militia, of the illegality of which step there could never be any doubt at all.

After the Restoration, when the military tenures were abolished, it was thought proper to ascertain the power of the militia, to recognise the sole right of the crown to govern and command them, and to put the whole into a more regular method of military subordination. And the order in which the militia now stands by law is principally built upon the statutes 13 Car. II c. 6; 14 Car. II. c. 3; 15 Car. II. c. 4; which were then enacted. It is true the two last of them are apparently repealed: but many of their provisions are re-enacted, with the addition of some new regulations, by subsequent militia laws; the general scheme of which is to discipline a certain number of the inhabitants of every county, chosen by lot, formerly for three, but now for five years (liable to be prolonged by the circumstance of the militia being called out and embodied), and officered by the lord-lieute-

nant, the deputy lieutenants, and other principal landholders, under a commission from the crown. They are not compellable to march out of their counties unless in case of invasion or actual rebellion within the realm (or any of his majesty's dominions or territories, stat. 16 Geo. III. c. 3), nor in any case compellable to march out of the kingdom. They are to be exercised at stated times; and their discipline in general is liberal and easy; but, when drawn out into actual service, they are subject to the rigors of the martial law, as necessary to keep them in order. This is the constitutional security which our laws have provided for the public peace, and for protecting the realm against foreign or domestic violence. See 1 Comm. 410, &c.

The last general acts, reducing into one all the laws relating to the militia, are 42 Geo. III. c. 90 for England, and c. 91 for Scotland; these ascertain the particular quota to be raised in each county and district: but which has, from time to time, been augmented and altered by subsequent acts. It is provided that, in cases of actual invasion or imminent danger thereof, and in cases of rebellion and insurrection, his majesty may embody and increase the militia: and, if parliament is not then sitting, they are to meet by proclamation in fourteen days. The militia of Ireland is regulated on principles nearly similar, by stat. 49 Geo. III. c. 120, amended by 53 Geo. III. c. 48; 54 Geo. III. c. 179, &c. The interchange of the British and Irish militia, so that each may serve in any part of the united kingdom, is allowed and regulated under stats. 51 Geo. III. c. 118, 128; 54 Geo. III. c. 10 (a temporary act).

The wives and families of militia men are provided for, when requiring parish relief, under the acts 43 Geo. III. c. 47 for England; 43 Geo. III. c. 89 for Scotland; and 51 Geo. III. c. 78, 52 Geo. III. c. 28 for Ireland. The pay and clothing of all the militia is provided for by annual acts.

The militia having, under various temporary acts, volunteered into the regular army, from time to time, and being at length considered as peculiarly applicable to that purpose, it was found expedient 'that a local militia should be established, trained, and permanently maintained, to be called forth and employed in case of invasion in aid of the regular forces for the defence of the realm.' This was accordingly effected, first as to England by 48 Geo. III. c. 111, and afterwards for Scotland by 48 Geo. III. c. 150. These acts are amended by several subsequent ones; but the system has never been extended to Ireland.

The militia of the city of London is regulated by stats. 36 Geo. III. c. 92, and 39 Geo. III. c. 82; and that of the Tower Hamlets by 37 Geo. III. c. 25, 75, 53 Geo. III. c. 132.

With respect to the militia of the cinque ports see 42 Geo. III. c. 90, § 155, referring to 13 and 14 Car. II. c. 2 and 15 Car. II. c. 4. See also 43 Geo. III. c. 100.

MILIUM, millet, in botany, a genus of the digynia order, and triandria class of plants; natural order fourth, gramina: CAL. bivalved, and uniflorous: COR. very short; stigmata pencil-like. There are eight species; of which the most remarkable is the

M. panicum, common millet, a native of India, but now commonly cultivated in many parts of Europe as an esculent grain. It rises, with a reed-like stalk, three or four feet high, and channelled: at every joint there is one reed-like leaf, which is joined on the top of the sheath, and embraces and covers that joint of the stalk below the leaf; this sheath is closely covered with soft hairs, but the leaf which is expanded has none. The top of the stalk is terminated by a large loose panicle, which hangs on one side, having a chaffy flower, which is succeeded by a small round seed. There are two varieties; one with white, and the other with black seeds; but they differ in no other particular. This plant is seldom cultivated in Britain but in small gardens, for feeding poultry; the seeds generally ripen well. They must be sown in the beginning of April, upon a warm dry soil, but not too thick, because the plants divide into several branches, and should have much room. When they come up they should be cleaned from weeds, after which they will in a short time get the better of them, and prevent the future growth. In August the seeds will ripen, when the plant must be cut down, and the seeds beaten out, as is practised for other grain; but, if it is not protected from birds, they will devour it as soon as it begins to ripen.

MILK'YWAY, *n. s.*

Sax. meelc, milc; Goth. *mialk*; Teut. *melch*; Dan. and Belg. *melk*. The liquor with which the mammalia supply their young; hence a name sometimes given to the white juice of certain plants: as a verb, to draw or suck out milk: milken and milky mean, consisting of, resembling, or yielding milk; and metaphorically, soft, tender, gentle: a milker is one who draws off the milk from animals: milklivered, cowardly, timorous: a milkman and milkmaid are dealers in milk: milksop, a spiritless, effeminate man: milk-tooth, an early kind of foal's tooth, see below: milk-thistle, milk-vetch, and milk-weed, are plants: milk-wort, a flower: milky-way, the galaxy; that part of the heavens which appears of a confused milky whiteness, from the abundance of its stars.

> She a black silk cap on him began
> To set, for foil of this *milkwhite* to serve.
>
> *Sidney.*

> Of a most notorious thief, which lived all his lifetime of spoils, one of their bards will say, that he was none of the idle *milksops* that was brought up by the fire-side, but that most of his days he spent in arms, and that he did never eat his meal before he had won it with his sword. *Spenser.*

> Come to my women's breasts,
> And take my *milk* for gall. *Shakspeare. Macbeth.*

I fear thy nature,
It is too full o' the *milk* of human kindness
To catch the nearest way. *Id. King Lear.*

I have given suck, and know
How tender 'tis to love the babe that *milks* me.
Shakspeare.

Milklivered man!
That bear'st a cheek for blows, and head for wrongs.
Id.

A *milksop*, one that never in his life
Felt so much cold as over shoes in snow. *Id.*

The bolt of Cupid fell,
It fell upon a little western flower;
Before *milkwhite*, now purple with love's wound;
And maidens call it love in idleness. *Id.*

This *milky* gentleness and course of yours,
You are much more at task for want of wisdom,
Than praised for harmful mildness. *Id.*

Pistachoes, so they be good and not musty, joined with almonds in almond *milk*, or made into a *milk* of themselves, like unto almond *milk*, are an excellent nourisher. *Bacon.*

Sir Fulke Grevil had much and private access to Queen Elizabeth, and did many men good; yet he would say merrily of himself, that he was like Robin Goodfellow; for when the maids split the *milkpans*, or kept any racket, they would lay it upon Robin: so what tales the ladies about the queen told her, or other bad offices that they did, they would put it upon him. *Bacon's Apophth.*

Some stars there are in our hemisphere, like those little sparkles in the galaxy, or *milky* circle, wherein ye can scarce discern any light. *Bp. Hall.*

Perhaps my passion he disdains,
And courts the *milky* mothers of the plains.
Roscommon.

Illustrious robes of satin and of silk,
And wanton lawns more soft and white than *milk*.
Beaumont.

The remedies are to be proposed from a constant course of the *milken* diet, continued at least a year. *Temple.*

When *milk* is dried with heat,
In vain the *milkmaid* tugs an empty teat.
Dryden.

His kine with swelling udders ready stand,
And lowing for the pail invite the *milker's* hand.
Id.

Would I could share thy balmy, even temper,
And *milkiness* of blood! *Id. Cleomenes.*

A *milkwhite* goat for you I did provide;
Two *milkwhite* kids run frisking by her side.
Dryden.

For breakfast and supper *milk* and *milkpottage* are very fit for children. *Locke.*

A lovely *milkmaid* he began to regard with an eye of mercy. *Addison.*

He is better acquainted with the *milkscore* than his steward's accounts. *Id.*

But give him port and potent sack;
From *milksop* he starts up mohack. *Prior.*

Some plants upon breaking their vessels yield a *milky* juice. *Arbuthnot on Aliments.*

Even your *milkwoman* and your nursery-maid have a fellow-feeling. *Id. History of John Bull.*

Broths and *milk*-meats are windy to stomachs troubled with acid ferments.
Floyer on the Humours.

The saltness and oyliness of the blood absorbing the acid of the chyle, it loses its *milkiness*. *Floyer.*

Milkteeth are those small teeth which come forth before when a foal is about three months old, and which he begins to cast about two years and a half after, in the same order as they grew. *Farrier.*

Nor need we with a prying eye survey
The distant skies to find the *milky-way*:
It forcibly intrudes upon our sight. *Creech.*

Capacious chargers all around were laid
Full pails, and vessels of the *milking* trade. *Pope.*

Not tasteful herbs that in these gardens rise,
Which the kind soil with *milky* sap supplies,
Can move the god. *Id.*

How many stars there must be, a naked eye may give us some faint glimpse, but much more a good telescope, directed towards that region of the sky called the *milky-way*. *Cheyne.*

That very substance which last week was grazing in the field, waving in the *milkpail*, or growing in the garden, is now become part of the man.
Watts's Improvement of the Mind.

O, bid him save their harmless lives,
Frae dogs, an' tods, an' butchers' knives!
But gie them guid cow-*milk* their fill,
Till they be fit to fend themsel. *Burns.*

MILK is a well known nutritious fluid, naturally formed in the breasts of women, and udders of other females, for the nourishment of their young. It consists of three parts, viz. the caseous, butyrous, and serous. The first comprehends the grosser earthy particles, which serve to suspend the butyrous part; and which, when coagulated by art, are formed into cheese. The second ingredient comprises the oily particles, or cream, which float on the surface of the milk, and can by agitation be converted into butter. The serous is the watery part which constitutes whey. The most wholesome milk is that which contains a due proportion of these three constituent parts. The milk of women, mares, and asses, nearly agree in their qualities, being very dilute, sweet though ascescent, and, when coagulated, easily broken down. The milk of cows, goats, and sheep, possesses properties widely different. Of these, cows' milk approaches nearest to that of the human breast. But the milk of goats is of a peculiar nature; as its oily and coagulable parts do not separate spontaneously, throw up no cream, and yield no butter. That of sheep is rich and nourishing; produces abundance of butter, but too unpalatable for use. Both these fluids afford a large proportion of strong and tough cheese. Cows' milk forms a very essential part of human sustenance, being adapted to every state of the body, but particularly to infants, after being weaned. It should therefore be drawn from sound, young, and healthy animals; as it is most nutritious when these are between three and four years old. Goats' milk is totally divested of smell, and perfectly white; and although, in general, when used medicinally, or by adults, it ought to be taken undiluted, yet the addition of a little water renders it more easily digestible by the infantine stomach.

MILK, in the wine trade, makes an efficacious forcing for the fining down of all white wines, arracks, and small spirits; but it is by no means to be used for red wines, because it discharges their color. Thus, if a few quarts of well-skimmed milk be put to a hogshead of red wine, it will soon precipitate the greater part of the color, and leave the whole nearly white; and this is of known use in the turning red wines, when pricked, into white; in which a small degree of

acidity is not so much perceived. Milk is, from this quality of discharging color from wines, of use also to the wine-coopers, for whitening wines that have acquired a brown color from the cask, or from having been hastily boiled before fermenting; for the addition of a little skimmed milk, in these cases, precipitates the brown color, and leaves the wines almost limpid, or of what they call a water-whiteness, which is much admired abroad, in wines as well as in brandies.

Milk, Medicinal Qualities of. Dr. Cullen reckons milk an intermediate substance between animal and vegetable substances; as well as between the chyle taken up from the intestines and the fully elaborated animal fluid. He observes that milk is suited to almost all temperaments; and it is even so to stomachs disposed to acescency, more than those substances which have undergone the vinous fermentation; it cures the heart-burn, checks vinous fermentation, and precipitates the lees, when, by renewal of fermentation, the wine happens to be fouled. It therefore very properly accompanies a great deal of vegetable aliment; although sometimes its ascescency is troublesome, either from a large proportion taken in, or from the degree of it. It is reckoned among those foods which occasion costiveness. Hoffman, in his experiments on milk, found that all kinds of it contained much water; and, when this was dissipated, found the residuum very different in solubility. Milk requires only a small exertion of the animal powers for its assimilation. In hectic complaints there is wanted an oily, bland food, approaching the animal nature; on these accounts milk is a diet peculiarly adapted to them, and, in general, to most convalescents, but chiefly those of inflammatory temperaments. Physicians have generally recommended boiled milk in preference to fresh, because milk kept for some time exposed to the air has gone so far to a spontaneous separation; whereas the heat thoroughly blends the whole; hence its resolution is not so easy in the stomach; and thus boiled milk is more costive than raw, and gives more fæces. Again, when milk is boiled, a considerable quantity of air is detached, as appears from the froth on the surface; and air is the chief instrument of fermentation in bodies; so that after this process it is not so liable to acescency: for these reasons it is proper for the robust and vigorous. Another difference of milk is, according as it is fluid or coagulated. The coagulated is of two kinds, as induced by eunet, or the natural acescency of the milk. The former preparation makes the firmer and less easily soluble coagulum; though, when taken with the whey unseparated, it is less difficult of solution, though more so than any other coagulum in the same case. Many nations use the latter form, which is easier soluble, but very much acescent, and therefore, in point of solution, should be confined to the vigorous, in point of acescency, to those who live on alkalescent food; and, in the last case, the Laplanders use it as their chief acescent condiment. From the same considerations it is more cooling, and in its other effects like all other acescent vegetables.

Dr. James Anderson, in his View of the Agriculture of the County of Aberdeen, has the following remark on the proper method of *keeping milk* and butter, which we quote, as it may prove useful. 'The pernicious practice,' says he, 'of keeping milk in leaden vessels, and salting butter in stone jars, begins to gain ground among some of the fine ladies in this county, as well as elsewhere, from an idea of cleanliness. The fact is, it is just the reverse of cleanliness; for, in the hands of a careful person, nothing can be more cleanly than wooden dishes; but under the management of a slattern they discover the secret which stone dishes indeed do not. In return, these latter communicate to the butter and the milk, which has been kept in them, a poisonous quality, which inevitably proves destructive to the human constitution. To the prevalence of this practice I have no doubt we must attribute the frequency of palsies, which begin to prevail so much in this kingdom; for the well known effect of the poison of lead is bodily debility—palsy—death!'

In Ireland, instead of collecting cream from day to day until a sufficient quantity is procured, as the practice is in this country, they churn the whole of the milk together. Thus, in summer, it is prepared in one or two days at most; and, it is worthy of remark, that the butter made in the hottest weather in Ireland is as completely cured for exportation as that which is made in autumn. Hence the advantages of the Irish dairies over those in England arise, not from the climate or soil, for they are nearly the same; nor from the stock, for that in Ireland is greatly inferior to the stock in England, and the best breed they have is in England; certainly, then, the difference must arise in the manufacturing only.

MILL (John), D.D., a very learned divine, born at Shap in Westmoreland, about 1645. He was a servitor of Queen's College, Oxford; and, on his entering into orders, became an eminent preacher, and was made prebendary of Exeter. In 1681 he was created D.D., and appointed chaplain in ordinary to king Charles II., and in 1685 he was elected principal of St. Edmond's Hall in Oxford. His edition of the Greek Testament, which renders his name memorable, was published about a fortnight before his death, which happened in June 1707 Dr. Mill was employed thirty years in preparing this edition.

With best tobacco finely *milled*,
Beats all Anticyra's pretences
To disengage the encumbered senses. *Id.*

Æsop's beasts saw further into a *mill-stone* than our mobile. *L'Estrange.*

A MILL is a machine for grinding corn, &c., of which there are various kinds, according to the different methods of applying the moving power; as water-mills, wind-mills, mills worked by horses, &c. The first obvious method of reducing corn into flour for bread, was by the simple expedient of pounding; which was for ages practised by the various descendants of Adam, and even continued in use among the Romans below the reign of Vespasian. But the process was very early improved by the application of a grinding power, and the introduction of millstones. This was equally known in the east and west. The Gauls and Britons were familiarly acquainted with the use of hand-mills before their conquest by the Romans; the Britons particularly distinguishing them, as the Highlanders and we do at present, by the appellation of querns, carnes, or stones. And to these the Romans added the very useful invention of water-mills. These machines were common in the country at the conquest of Lancashire. That the Romans introduced these, with their other refinements among us, the British appellations of a water-mill seem to prove; the melin of the Welsh and Cornish, the mul, meill, and melin of the Armoricans, and the Irish muilean and muiland, being all evidently derived from the Roman mola and molendinum. The Britons universally adopted the Roman name, but applied it, as we do, only to the Roman mill; and one of these was probably erected at every stationary city in the kingdom. One (says Mr. Whitaker) plainly was at Manchester, serving equally the purposes of the town and the accommodation of the garrison. And one alone would be sufficient, as the use of hand-mills remained very common in both, many having been found about the site of the station particularly; and the general practice having descended among us nearly to the present period. Such it would be peculiarly necessary to have in the camp, that the garrison might be provided against a siege. And the water-mill at Manchester was fixed immediately below the Castle Field and the town, and on the channel of the Medlock. There, a little above the ancient ford, the sluice of it was accidentally discovered about thirty years ago. On the margin of Dyer's Croft, and opposite to some new constructions, the current of the river accidentally swelled with the rains, and, obstructed by a dam, broke down the northern bank, swept away a large oak upon the edge of it, and disclosed a long tunnel in the rock below. This has been since laid open in part with a spade. It appeared entirely uncovered at the top, was about a yard in width, and another in depth, but gradually narrowed to the bottom. The sides showed every where the marks of the tool on the rock, and the course of it was parallel with the channel. It was bared by the flood about twenty-five yards only in length, but was evidently continued for several yards farther; having originally begun, as the nature of the ground evinces, just above the large curve in the channel of the Medlock.

MILL WORK. Some of the principal mechanical arrangements employed for communicating

motion, in the construction of a mill, have already been examined under the head of MECHANICS; and the formation of COTTON and FLAX mills have been discussed in the articles devoted to those subjects. We are now, however, to examine those branches of the mill-wright art, which lead to a more practical acquaintance with the construction of wheels.

A mill, in the proper sense of the word, signifies a machine for grinding corn; though, in a more general sense, it is applied to all machines which have a horizontal circulatory motion. Mills are distinguished by particular names, sometimes taken from the powers by which they are moved, and sometimes from the uses to which they are applied. Hence they are called hand-mills, horse-mills, water-mills, fulling-mills, wind-mills, corn-mills, boring-mills, &c.

It may be advisable, prior to our entering upon the formation of the teeth of wheels, to furnish a general definition of the terms most commonly in use:

Cog-wheel is the general name of any wheel which has a number of teeth or cogs placed round its circumference.

Pinion is a small cog-wheel that has not in general more than twelve teeth; though, when two toothed wheels act upon one another, the smallest is not unfrequently distinguished by this term; as is also the trundle, lantern, or wallower, when talking of the action of two wheels.

Trundle, lantern, or *wallower,* is sometimes used in lieu of a pinion.

When the teeth of a wheel are made of the same material, and formed of one piece with the body of the wheel, they are called teeth; when of wood, or some other material, and affixed to the outer rim of the wheel, cogs; in a pinion they are called leaves; in a trundle, staves.

When speaking of the action of wheel-work, in general, the wheel which acts as a mover is called the leader, and the one upon which it acts the follower.

If a wheel and pinion are to be so constructed that the one shall give, and the other receive impulse, so that the pinion shall perform four revolutions in the time that the wheel is performing one, they must be represented by two circles, which are in proportion to each other as 4 is to 2. When these two circles are so placed that their outer rims shall touch each other, a line drawn from the centre of the one to the centre of the other, is termed the line of centres; and the radii of the two circles, the proportional radii. These circles are sometimes called proportional circles; but by mill-wrights in general, pitch lines.

The teeth, which are to communicate motion, must be formed upon these two circles. The distance from the centres of two circles to the extremities of their respective teeth, is called the real radii; and in practice the distance between the centres of two contiguous teeth, that is, the distance from the centres of two teeth measured upon their pitch line, is called the pitch of the wheel. The straight part of a tooth, which receives the impulse, is called a flank; and the curved part, that imparts the impulse, the face.

Two wheels acting upon one another in the same plane, having their axes parallel to each other, are called spur geer; when their axes are at right, or other angles, bevelled geer.

If two cylinders be placed in close contact, motion cannot be communicated to the one without that motion, by means of the irregularities of their surfaces, being communicated to the other, and the smaller cylinder shall perform exactly as many revolutions, to one revolution of the larger cylinder, as the larger cylinder contains upon its circumference so many measured circumferences of the smaller cylinder.

Wheels, however, which act by their surfaces only, are ill calculated to transmit motion to any considerable extent, as the motion which the follower has acquired is not of sufficient power to overcome the great resistance which would, in such case, be opposed to it; consequently it becomes necessary to have projections or teeth, and that form of the teeth will be the best which causes the wheel to act as though the motion were communicated by contact of the pitched lines. See WHEEL WORK.

Spur gear. If the three circles 1, 2, 3, fig. 1, plate I, MILL WORK, in contact with the point *a*, be made to revolve about their centres, so that they shall continually touch at the point *a*, their motions will be similar to what would have been generated by one communicating motion to the other two by contact; and circle 3 will move as though rolling on the external surface of circle 1, and internal surface of circle 2, and consequently become the generating circle of the exterior epicycloid on circle 1, and the generating circle of the interior epicycloid on circle 2. As the diameter of circle 3 is equal to the radius of circle 2, the interior epicycloid will be a straight line passing through B, the centre of circle 2; and, supposing the point *a* to have performed that portion of a revolution which places it at K, a portion of the exterior epicycloid will be represented by the line EK, and a portion of the interior epicycloid by DK. Therefore, as the epicycloids, DK and EK, are both generated by one motion of the same point on the same circle, they will continually touch at the generating point, and the total surface of EK will pass over the total surface of DK; and if the epicycloid EK be affixed to the external surface of circle 1, and act upon the portion of the epicycloid DK, it will transmit motion to circle 2, as though that motion were communicated by contact of the pitch lines; which proves that EK presents us with the best form of tooth, and which tooth would, when acting upon the radii of the wheel to be driven, move it as though the motion were communicated by contact.

Fig. 2 represents a mode of forming the teeth of wheels when they are to act upon a trundle. Circle 1 represents the pitch line of the wheel; and circle 2 the pitch line of the trundle; which are supposed to act by contact at the point *a*. When *a* arrives at a^1, it will have traced the portion of an epicycloid represented by a^1 a^2; and, as *a* is the generating point of the epicycloid, the distance from *a* to a^1, and from *a* to a^2, will be equal; and the epicycloid a^1 a^2, being generated by the proportional circle or pitch line of

J. Shury sculp.

the trundle, presents us with the most proper form for the tooth of a wheel that is to drive a trundle with circular staves posited in its pitch line.

We shall now proceed to the practical mode of applying these rules. Let circle 2 be the proportional circle or pitch line of a trundle; and circle 1 the pitch line of a wheel which is to drive that trundle; and by the revolutions of these two circles let the portion of an epicycloid, a^1 a^2, be generated, so that when a line is drawn from a^2 to the centre of circle 1, it will intersect that circle at b, whose distance from a^1 is such, that, when the semi-diameter of a staff of the trundle is subtracted from it, the remainder will be equal to half the intended thickness of the tooth of the wheel. Set off perpendicularly to the epicycloid inwards the semi-diameter of one of the staves, at so many points that you will be able to trace through the points thus set off a line parallel to the epicycloid a^1 a^2, which line will be the face of the tooth of the wheel, being less than the tooth formed by the epicycloid a^1 a^2 by the semi-diameter of a staff of the trundle: indeed the diminution must be rather more, as the width, $g\,g$, must be made sufficient for the staves to clear themselves, as the whole of the epicycloidal line must act upon their surface.

To describe the teeth of a wheel for a trundle, by means of circular arcs, let us suppose A B, fig. 3, to be the line of centres, C D the pitch line of the wheel, E F the pitch line of the trundle, and the centre of the staff G to be in the line of centres A B; then, by placing one foot of the compasses in the centre of the staff G, we can describe the arc $m\,n$, which is the form of the face of a tooth, sufficiently near that of an epicycloid for common purposes.

To find the form for the teeth of a wheel, and the leaves of a pinion, which are to act together, we must set off on the pitch lines the points $m\,n\,a$, and $p\,q\,r$, &c., fig. 4, according to the proper thickness of, and distance between, the teeth and leaves, and from these points draw radii to serve as the flanks of the teeth. The spaces must be of sufficient depth to allow for the action of the curved part of the teeth and leaves.

Then, with the generating circle 1, whose diameter is equal to the proportional radius of the pinion, describe upon the extremities of the sides of each tooth, and upon the circumference of the proportional circle of the wheel as a base, the epicycloids $a\,b$, $b\,n$; and, with the generating circle 2, describe upon the proportional circle of the pinion as a base the epicycloid q D, which will give the required form of the teeth and leaves.

For, if the projecting epicycloid $a\,b$ push against the radius $f\,r$ of the proportional pinion, the wheel and pinion will move with equal velocity; and a similar effect will be produced by the epicycloid p D being pushed by the radius $o\,m$ of the wheel towards the line of centres.

When one wheel is to conduct another, it is not necessary that the wheel to be conducted should have teeth of an epicycloidal form; and, were the teeth not subject to wear by friction, there would be no occasion to extend the teeth of the conducted wheel beyond the pitch line; but, such being the case, it becomes necessary to form the teeth of the conducted wheel in the manner represented in fig. 5 by the dotted lines.

Mr. Buchanan, in his Essay on the Teeth of Wheels, objects to this mode of forming the teeth of the conducted wheel, and recommends that a trundle, or wheel with cylindrical staves, should be adopted, as it will be less acted upon in approaching the line of centres, and consequently have less friction than a pinion or wheel the sides of whose teeth tend to the centre.

'This will appear,' says he, 'by fig. 6, which represents a staff a of a trundle, and a leaf b of a pinion, turning round on the same centre A, and a tooth adapted to each, turning on a common centre B. The thickness of each of the teeth, and the proportional circle of both wheels, are the same, and the proportional circles of the pinions are also equal, and teeth are each made of the greatest length which the intersection of the curves will admit, which turns out considerably greater in the tooth adapted to the staff. The shaded parts represent the tooth adapted to, and acting upon, the staff; and the dotted lines represent the tooth adapted to, and acting upon, the leaf. The teeth, in both cases, are represented as just at the point where they would cease to move the leaves or staff uniformly; and it appears the staff is conducted considerably further beyond the line of centres than the leaf; hence the staff will be less acted upon in approaching the line of centres.'

As the trundle in common use is very weak and imperfect, Mr. Buchanan conceived that a wheel might be made which would combine the advantages of both the pinion and trundle; and accordingly had some wheels made, which appeared to answer every expectation.

'These wheels,' says he, 'were made of cast iron; they were each cast of one solid mass. Fig. 7 represents the edge view, and fig. 8 a section of one of them; whereby is shown the manner in which the teeth are supported like the staves of a trundle at each end, and like the leaves of a pinion at the roots, but so very thin there as to run no risk of having the common fault of pinions just now noticed. I mentioned,' he continues, 'in cases where the pinion had few teeth, that in the conductor, whether wheel or pinion, staves should be preferred; but it is obvious that the method just described, of making a small trundle of cast iron, would not apply to a wheel of a great number of staves. Nor is it in that case so necessary; as the greater the number of teeth are, the longer they will be in losing their proper figure. In such cases, therefore, staves, strictly speaking, should not be used, but teeth made so as to produce the same effect; that is, having their acting parts of the figure of a staff. What is meant will be better understood by inspecting fig. 9, where the lines show the alteration necessary on the tooth A, in order to make it produce the effect of a staff; which staff is represented by the faint dots. The dotted lines on d represent the alteration requisite to adapt it to the staff; it being necessary, as formerly proved, to have it a different epicycloid from what is required to adapt it to a tooth whose acting part is a straight line, tending to the centre of its proportional circle.'

'Teeth,' says Mr. Tredgold, 'seem to be very well adapted for various purposes, when formed on the principle recommended in the preceding article. I therefore will endeavour to show a simple method of describing such teeth. It must be observed, that the teeth, to resemble staves, are to be always on the conducted wheel or pinion; thus affording the peculiar advantage of the wheel and trundle in either increasing or diminishing velocity.

'Let the teeth be divided as usual on the pitch lines E E, F F, fig. 10; and on the conducted wheel C describe circles, as though they were to be staves. Conceive the centre of one of these staff teeth to be in the line of centres at A, and draw the line A B joining the centres of the staff teeth. Then the radius A *b*, from the centre A, will describe the curved side *b c* of the tooth of the conductor, and the curved part *b a* of the conducted wheel. And since this radius is equal to the pitch diminished by half the diameter of the circle of the staff teeth, and the centres will always be in the pitch lines of the wheels, all the other teeth may be easily described.'

When a pinion is to act internally, as in fig. 1 plate 2, it is evident that the teeth may be formed on the principles already laid down, with this difference only, that the epicycloid, generated by the proportional circle of the pinion upon that of the wheel, should be an interior epicycloid. The internal pinion may be adopted in many cases with advantage, as it has less friction than the external one.

To illustrate this, let A, fig. 2, be the pitch line of a wheel, B that of an internal pinion, and *c* that of an external pinión. Suppose the circle A to be moved till the point *a* arrives at *b*, and that the points *c*, *d*, in the circles B, C, have both moved over a space equal to *a*, *b*. Now it is evident that the distance from *c* to *b* is much less than that from *b* to *d*, and, consequently, had the circles moved one another by means of teeth, a tooth of the interior circle B, in the same part of a revolution, would have slid over a smaller part of a tooth of the circle A than a tooth of the exterior circle C, and therefore would have had less velocity. But, other things being equal, the less the velocity, the less the friction; an interior pinion has consequently less friction than an exterior one.

It is upon this principle that bevelled wheels have less friction than external spur wheels; bevelled wheels acting in a mean situation between external and internal spur wheels.

The rack and pinion should be made on the principles of spur geers; with this difference only, that, in forming the teeth, the cycloid is, for reasons obvious from its definition, used in place of the epicycloid.

Dr. Johnson gives this definition of the cycloid:—'A geometrical curve, of which the genesis may be conceived by imagining a nail in the circumference of a wheel: the line which the nail describes in the air, while the wheel revolves in a right line, is the cycloid.'

Thus A B C, fig. 3, is a cycloid generated by the point *a* in the circle D, while it revolves in the right line A C.

Fig. 4 represents the teeth of a rack and pinion, formed in what seems the best mode, in cases where a great weight is attached to the rack. The leaves of the pinion are made as long as the curve will admit, in order to prevent them from beginning to act before they arrive in the line passing through the centre of the pinion, perpendicular to the rack. Were they to act much before they arrived in that line, which may be considered as the line of centres, and against a very great weight, they would be apt to jam, and run the risk of their being broken, or at least very much increase the friction.

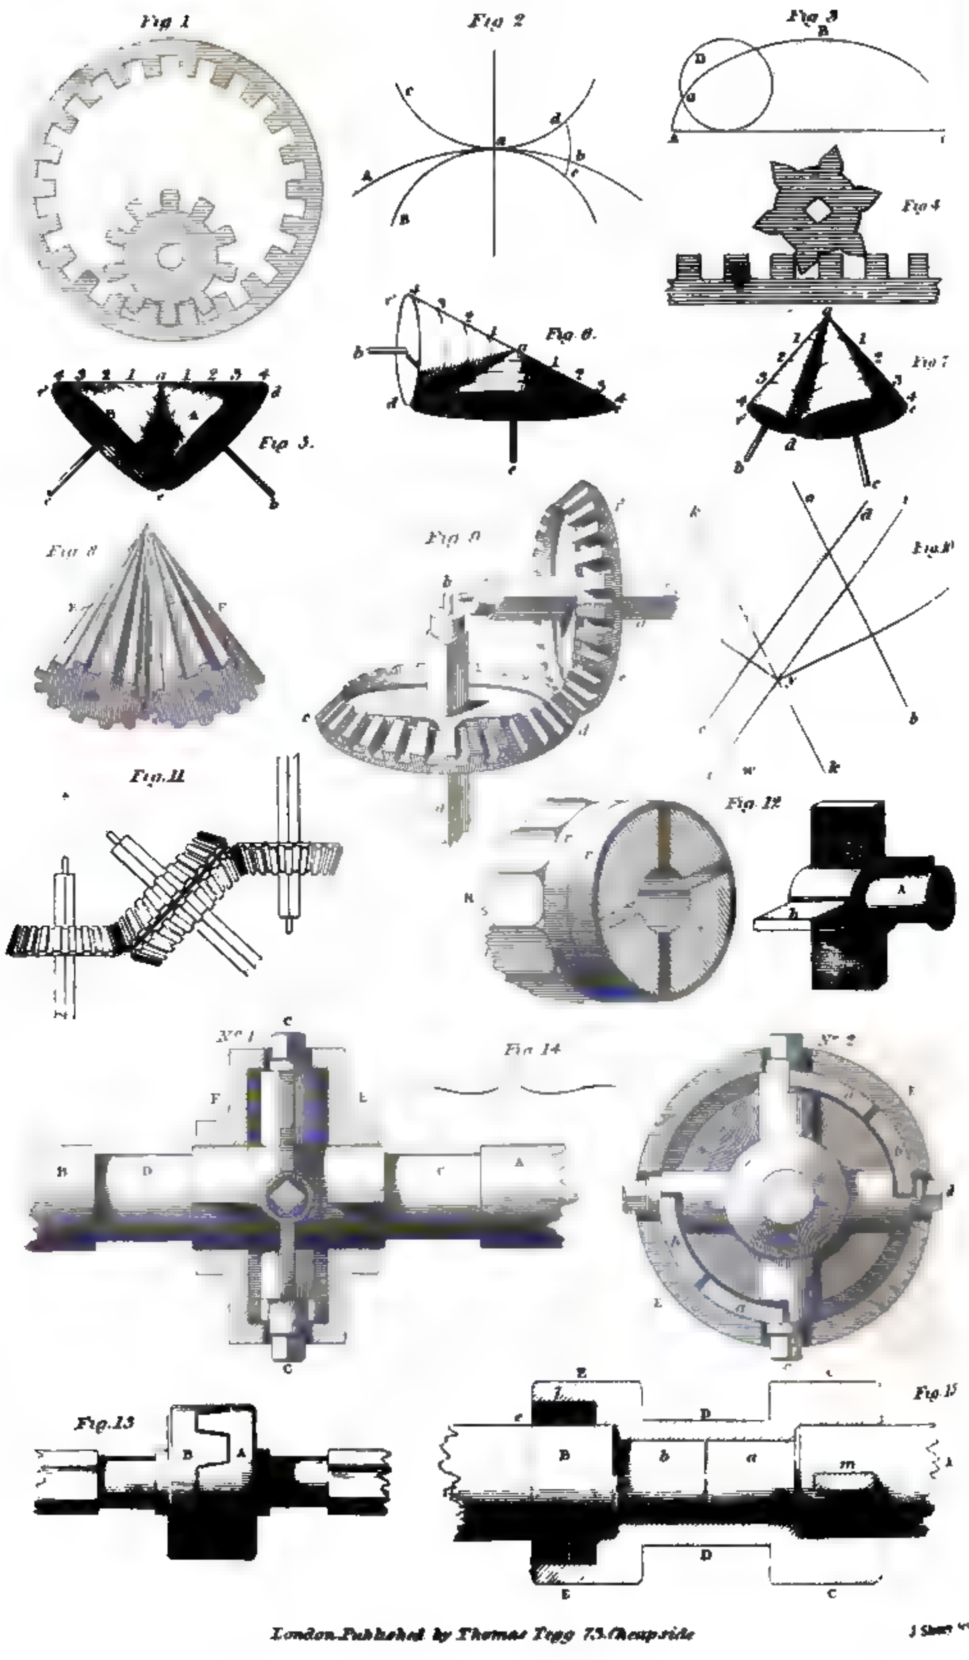
Mistaken attempts at economy have often prompted the use of wheels of too small diameter. This is an evil which ought carefully to be avoided. Knowing the pressure on the teeth, we cannot, with propriety, reduce the diameter of a wheel below a certain measure.

Suppose, for instance, a water-wheel of twenty horses' power, moving at the pitch line with a velocity of three feet and a half per second: it is known that a pinion of four feet diameter might work into it without impropriety; but we also know that it would be exceedingly improper to substitute a pinion of only one foot diameter, although the pressure and velocity at the pitch lines in both cases would be, in a certain sense, the same. In the case of the small pinion, however, a much greater stress would be thrown on the journeys (or journals) of the shaft. Not, indeed, on account of torsion or twist, but on account of transverse strain, arising as well from greater direct pressure as from the tendency which the oblique action of the teeth, particularly when somewhat worn, would have to produce great friction, and to force the pinion from the wheel, and make it bear harder on the journals. The small pinion is also evidently liable to wear much, on account of the more frequent recurrence of the friction of each particular tooth.

That these observations are not without foundation is known to mill-wrights of experience. They have found a great saving of power by altering corn mills, for example, from the old plan of using only one wheel and pinion (or trundle) to the method of bringing up the motion by means of more wheels and pinions, and of larger diameters and finer pitches. The increase of power has often, by these means, been nearly doubled, while the tear and wear has been much lessened; although it is evident the machinery, thus altered, was more complex.

The due consideration of the proper communication of the original power is of great importance for the construction of mills on the best principles. It may easily be seen that, in many cases, a very great portion of the original power is expended before it is actually applied to the work intended to be performed.

Notwithstanding the modern improvements in this department there is still much to be done. In the usual modes of constructing mills due attention is seldom given to scientific principles. It is certain, however, that, were these principles better attended to, much power that is necessarily expended would be saved. In general this might be in a great measure obtained by bringing on the desired motions in a gradual manner, beginning with the first very slow, and



London, Published by Thomas Tegg 73 Cheapside

gradually bringing up the desired motions by wheels and pinions of larger diameters. This is a subject which should be well considered before we can determine, in any particular case, what ought to be the pitch of the wheels. In the case above alluded to, where the supposition is a pinion of four feet diameter, or of one foot diameter, it is obvious that the same pitch for both would not be prudent. That for the small pinion ought to be much less than that which might be allowed in the case of the larger pinion. It is also equally obvious that the breadth of the teeth, in the case of the small pinion, ought to be much greater than that in the case of the larger pinion. It is evident, however, that, although great advantage may often be derived from a fine pitch, there is a limit in this respect, as also with regard to the breadth.

Hitherto our enquiry has been confined to what is called spur-geer, or the action of wheels and pinions whose axes are parallel; we come now to speak of bevel-geer, or the action of wheels of which the axes are angular to each other.

The principle consists in two cones rolling on the surface of each other, as the cones A and B revolving on their centres *a b*, *a c*, fig. 5; if their bases are equal they will perform their revolutions in one and the same time; or any other two points equally distant from the centre *a*, as *d* 1, *d* 2, *d* 3, &c., will revolve in the same time as *f* 1, *f* 2, *f* 3, &c. In the like manner, if the cones *a*, *d*, *e* be twice the diameters at the base *d e* as the cones *a*, *f*, *e*, are, then if they turn about their centres, when the cone *a f d*, figs. 6 and 7, has made one revolution, the cone *a d e* will have made but half a revolution; or when *a f e* has made two revolutions, *a d e* will have made but one, and every part equally distant from the centre *a*, as *f* 1, *f* 2, *f* 3, &c., will have made two revolutions to *e* 1, *e* 2, *e* 3, &c.; and if the cones were fluted, or had teeth cut in them, diverging from the centre *a* to the bases *d*, *c*, *e*, *f*, they would then become bevel geer. The teeth at the point of the cone, fig. 8, being small, and of little use, may be cut off at E and F, figs. 8 and 9, where the upright shaft *a b*, with the bevel-wheel *c d*, turns the bevel-wheel *e f* with its shaft *b g*, and the teeth work freely into each other. The teeth may be made of any dimensions, according to the strength required; and this method will enable them to overcome a much greater resistance, and work smoother than a face-wheel and wallower of the common form can possibly do; besides, it is of great use to convey a motion in any direction, or to any part of a building, with the least trouble and friction.

The method of conveying motion in any direction, and proportioning or sharpening the wheels thereto, is as follows:—let the line *a b* represent a shaft coming from a wheel; draw the line *c d* to intersect the line *a b* fig. 10, in the direction that the motion to be conveyed is intended, which will now represent a shaft to the intended motion.

Again, suppose the shaft *c d* is to revolve three times, whilst the shaft *a b* revolves once; draw the parallel line *i i*, at any distance not too great (suppose one foot by a scale), then draw the parallel line *k k* at three feet distance, after which draw the dotted line *w x*, through the intersection of the shaft *a b* and *c d*, and likewise through the intersection of the parallel lines *i i* and *k k*, in the points *x* and *y*, which will be the pitch-line of the two bevel-wheels, or the line where the teeth of the two wheels act on each other, as may be seen fig. 11, where the motion may be conveyed in any direction.

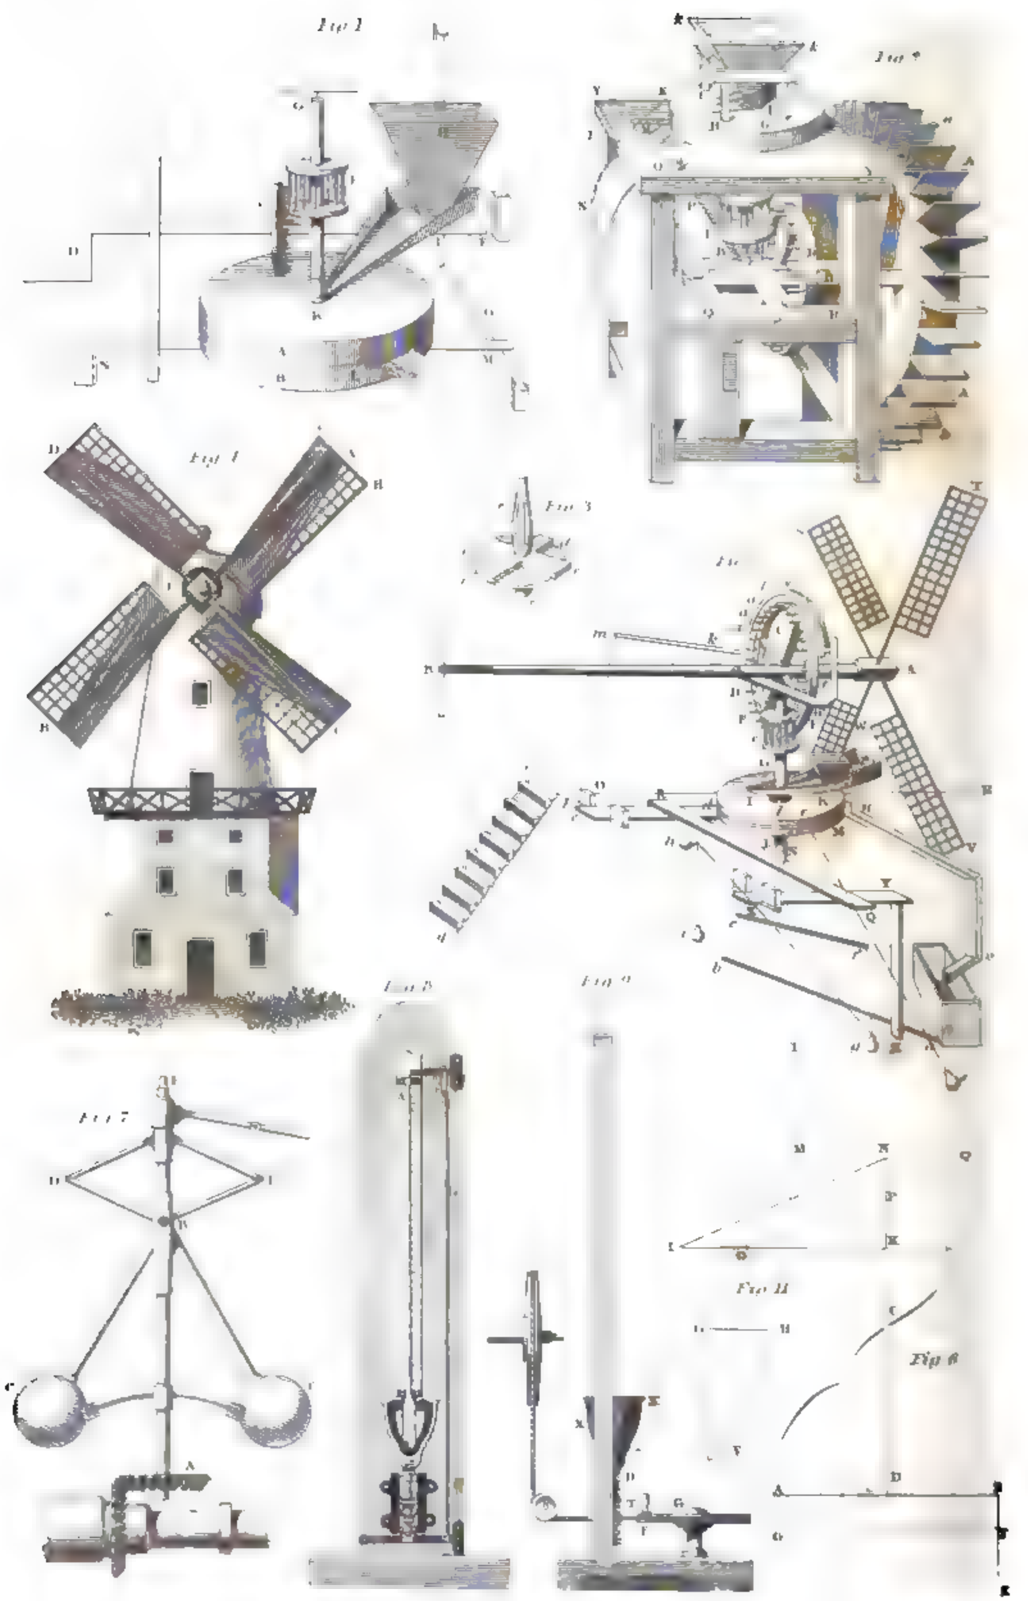
In almost all modern mills the shafts or spindles for the conveyance of motion, and support of wheels, are made of iron, either wrought or cast. Square shafts are the most common, but sometimes octagon and round ones are used; and if they are very large they are cast hollow, like pipes, and the gudgeons fixed in at the ends by wedges; but the pivots should always, if possible, be formed of the same piece of metal, as the slightest possible deviation from the straight line causes them to strain, and work very irregularly in their bearings. In wooden shafts this is impracticable, and it is one of the greatest objections to the use of them. The best method of fixing gudgeons into wooden shafts is shown in fig. 12. Here A is the gudgeon, made in cast iron, turned true; it has four leaves *a*, *b*, *c*, *d*, forming a cross, which is let into the end of the wooden shaft R; the front edge of each leaf is considerably thinner than the back, so that a pair of strong iron hoops *r r*, being driven tight on the end of the shaft, closes the wood round the cross, and holds it fast, and, the back of the leaves being wider than the front, it will not come out. As an additional security screws are sometimes put in: these are put through holes in the arms of the cross, which are then made flat the other way, and do not go so far into the wood. The screws go into the timber a considerable distance, where a mortise is cut into the wood, to meet the end of the bolt, and an iron nut is dropped in, to screw the bolt into, when it is turned round by a screw-driver. By this contrivance a gudgeon may be fitted into a wooden shaft very fast; but still it will never come into competition with iron shafts, when the gudgeon is made all in one solid piece with the whole of the shaft. A judicious mechanic will never make more than two bearings upon any one shaft, if it can be avoided, because, if the three by any means, as the warping of the frame work or other cause, get the smallest possible quantity out of the straight line, they can never work well afterwards, but will always strain and wear the bearings with great friction. In very extensive mills, such as woollen and cotton mills, breweries, &c., when the buildings are of great length, it becomes necessary to join several shafts together in length, to reach from one end to the other of a mill. The manner of making the joinings is of some consequence: it is necessary that every shaft should have a bearing at each end, and consequently that the connexion of the ends of every one should be made by uniting the ends of the shafts which project beyond their bearings. This can be done in various ways; one is by having the ends of each of the shafts provided with circular heads A B, fig. 13, which have teeth in one, and corresponding indentations in the other,

to receive them, and thus one is made to turn the other about, at the same time that if any slight settlement of the building or other cause depresses one of the bearings, or raises another, so as to put the two shafts out of the perfect straight line they ought always to preserve, these joints will admit the slight flexure, and still communicate the motion of one shaft to the other.

As this accidental settlement in large buildings is almost unavoidable, in some degree, care should be taken to make such joints as will admit of a trifling bending. Sometimes the ends of the shaft are made circular, and turned quite true in the lathe; then a metal tube or collar is fitted truly upon both, to cover the joint, and connect them, a bolt being put through each end, which unites both shafts with the collar, and thus by means of it causes the one to turn the other round. This method is sometimes used to save the great expense of having a bearing at each end of every length of shaft, one bearing to each length being then sufficient, the other end of the shaft being supported by this collar, connecting it with the end of the adjacent length just where it projects beyond its bearing. But this is not a good method, as the shafts are apt to bend and work with so much friction in the bearings, if they get the least out of the straight line, because these kind of joints will not admit any flexure of the shaft; or, if they do, they will only bend on one side, whereas it is necessary for the joints to bend successively on all sides, when the bearings are not precisely in a straight line. Fig. 14 represents a coupling-box, used by Messrs. Murray and Co. of Leeds, for connecting the lengths of a long line of shaft which are to carry a heavy strain: it is so made that it will communicate the motion in the manner of a universal joint, if they should be out of the line. Let A, B, be the two shafts to be united; C, D, their necks or collars which lie in the bearings: the ends projecting beyond these have boxes E, F, fixed on them, either by a square with wedges, or by a round part with a fillet; one of these boxes E has a piece projecting from the inside of it on each side, and extending into the other box, as is shown at *a a*, No. 2, which is an inside view: the other box F has two similar pieces projecting from it at *b b* into the other box E; within the boxes an iron cross *c c d d* is situated; it has screws fixed into the ends of the cross, and by these the motion is communicated: thus the pieces *a*, *a*, when the shaft A and box E are turned round in the direction of the arrows No. 2, act against the screws *c*, *c*, of the cross, and turn it about: at the same time the other two screws *d*, *d*, at the other arms of the cross, press against the pieces *b*, *b*, which belong to the box and shaft B, thus turning them round: the cross is placed quite detached in the boxes, and thus acts as a universal joint, to communicate the motion of one to the other: the screws *c c*, *d d*, at the ends of the cross, are only put in that the acting points may be made of steel, and made smooth to have but little friction in these parts. Another method of uniting shafts by Mr. Murray is shown at fig. 15: it has the advantage of requiring only one bearing for every length of shaft, whereas the above method requires one for each end of every length. A, B, represent the two shafts; each has a pivot formed at the end: these pivots are fitted into a coupling piece C D E, which is bored out truly to fit them inside, and the outside turned true, with a neck D D, which is received and fitted into a bearing: the two shafts A, B, are connected with the coupling piece D, at C and E, by means of a cross key *l m*, put through each shaft, and the ends of them received in notches made within side of the coupling piece at C and E, where it receives the ends of the shafts. It is to be observed that the shafts do not fit tight in these parts E and C, but only in the pivots *a*, *b*, within, by which means they have liberty of a little motion, and this without straining the bearing in which D runs, because it is only the short coupling piece which is received therein; and consequently any trifling deviation from the straight line will not strain it, because of the play allowed in the fittings.

In treating of the mill in its complete state we may commence with its simplest form. The hand-mill will first engage our attention. It is shown in fig. 1, plate III. where A and B represent the two stones between which the corn is ground, and of which the upper one A turns round, but the lower one B remains fixed and immoveable. The upper stone is five inches thick, and twenty-one inches broad; the lower one somewhat broader. C is a cog-wheel, having sixteen or eighteen cogs, which go into the trundle F, having nine spokes fixed to the axis G, the latter being firmly inserted into the upper stone A, by means of a piece of iron. H is the hopper into which the corn is put: I the shoe to carry it by little and little through a hole at K, in betwixt the stones, where being ground into meal it comes out through the eye at L. Both stones are enclosed in a circular wooden case, of such a size as will admit the upper one to run freely within it. The under surface of the upper stone is cut into grooves, as represented at Q, which enable it to throw the meal out at the eye L more perfectly than could be done if it were quite plain. Neither of them are entirely flat, the upper one being somewhat concave, and the under one convex. They nearly touch at the edges, but are at some distance in the middle, in order to let the corn go in between them. The under stone is supported by strong beams, not represented in the figure; the spindle G stands on the beam M N, which lies upon the bearer O. One end of this bearer rests upon a fixed beam, and the other has a string fixed to it, and going round the pin P, by the turning of which the timbers O and M N may be raised or lowered, and thus the stones put nearer, or removed farther from each other, in order to grind fine or coarse. When the corn is to be ground it must be put into the hopper by little at a time. A man turns the handle D, and thus the cog-wheel and trundle are carried round also together with the stone A. The axis G is angular at K; and, as it goes round, shakes the shoe I, and makes the corn fall gradually through the hole K. The upper stone going round grinds it, throwing out the meal, as already said, at the eye L. Another handle, if thought proper, may be put at

MILL WORK.



London, Published by Thomas Tegg, 73, Cheapside.

J. Shury Sculp.

the other end of the handle E. The spindle must go through both stones, in order to reach the beam M N, and the hole through which it passes is fastened with leather or wood, so that no meal can pass through.

The construction of a horse-mill does not differ very materially from that of the hand-mill just described; instead, however, of the handle D, the spindle is furnished with a long horizontal lever and cogged wheel, which turns the trundle and stones, as already mentioned.—The stones are much heavier than in the hand-mill.

The mills most commonly in use for grinding corn are water-mills, the construction of which is not essentially different from that of the hand or horse-mills. The lower mill-stone, as already mentioned, is fixed, but the upper one moveable upon a spindle. The opposite surfaces of the two stones are not flat, but the one convex and the other concave, though in a very small degree. The upper stone, which is six feet in diameter, is hollowed only about an inch in the middle, and the other rises three-quarters of an inch. They approach much nearer each other at the circumference, and the corn begins to be ground about two-thirds of the radius distance from the circumference, and there it makes the greatest resistance, the space between the two stones being in that place only about two-thirds or three-fourths of the thickness of a grain of corn; but as these stones, as well as those of the hand-mill or horse-mill, can be separated a little from each other, the meal may be made fine or coarse in them, as well as in the two former mills.

To cut and grind the corn, both the upper and under stones have furrows cut in them, as is observed in the hand-mill These are cut perpendicularly on one side, and obliquely upon the other, by which means each furrow has a sharp edge, and by the turning of the stones the furrows meet like a pair of scissars, and by cutting the corn make it grind the more easily. They are cut the same way in both stones when they lie upon their backs, by which means they run crossways to each other when the upper one is inverted and turned round; and this greatly promotes the grinding of the corn, great part of which would be driven onward in the lower furrows, without being ground at all, if both lay the same way. When the furrow becomes blunt and shallow, by wearing, the running stone must be taken off, and the furrows cut deeper in both by means of a chisel and hammer. Thus, however, by having the furrows cut down a great number of times, the thicknesses of both stones are greatly diminished; and it is observed, that in proportion to the diminution of the thickness of the upper stone, the quantity of flour also diminishes.

By means of the circular motion of the upper stone the corn is brought out of the hopper by jerks, and recedes from the centre towards the circumference by the centrifugal force; and, being entirely reduced to flour at the edges when the stones nearly touch one another, it is thrown at last out at the hole called the eye, as already mentioned. In Scotland it is frequent to have the stones without any furrows, and only irregularly indented with small holes, by means of an iron instrument. Stones of this kind last a much shorter time than those with furrows, the latter being fit for use for thirty or forty years, while the former seldom or never last more than seven. The under mill-stone is considerably thicker than the upper; and therefore, when both have been considerably worn by use, the lower one is frequently taken up, and the upper one put in its place, the former being converted into a running stone.

Water-mills are of three kinds, viz. breast-mills, undershot-mills, and overshot-mills. In the former the water falls down upon the wheel at right angles to the float-boards or buckets placed all round to receive it; if float-boards are used it acts only by its impulse; but, if buckets, it acts also by the weight of water in the buckets in the under quarter of the wheel, which is considerable. In the undershot-wheel float-boards only are used, and the wheel is turned merely by the force of the current running under it, and striking upon the boards. In the overshot-wheel the water is poured over the top, and thus acts principally by its weight; as the fall upon the upper part of the wheel cannot be very considerable, lest it should dash the water out of the buckets. Hence it is evident that an undershot-mill must require a much larger supply of water than any other; the breast-mill the next, unless the fall is very great; and an overshot-mill the least. Dr. Desaguiliers found that a well-made overshot-mill would perform as much work as an undershot one, with one-tenth part of the quantity of water required by the other.

Plate III. fig. 2, shows the construction of a common water-mill, where A A is the large water-wheel, commonly about seventeen or eighteen feet diameter from a, the extremity of any float-board, to b the extremity of the opposite one. This wheel is turned round by the falling of the water upon the boards from a certain height, and the greater the height, provided the water runs in an uninterrupted stream, the smaller quantity will be sufficient to turn the mill. This wheel is without the mill-house, but the wheel has an axle B B of considerable length, which passes through a circular hole in the wall, and has upon it a wheel D, of eight or nine feet diameter, having sixty-one cogs, which turn a trundle E of ten staves or spokes; by which means the trundle, and consequently the mill-stone, will make six revolutions and one-tenth for every revolution of the wheel. The odd cog, commonly called the hunting cog, is added, that as every one comes to the trundle it may take the staff behind that one which it took at the last revolution; and thus all the parts of the cogs and rounds which work upon one another will wear equally, and to equal distances from one another, in a little time; by which means a true uniform motion will be produced through the whole work. The trundle is fixed upon an iron axis called the spindle, the lower end of which turns in a brass pot fixed at F in the horizontal beam S T, called the bridge-tree; and the upper part of the spindle turns in a wooden bush, fixed into the lower mill-stone, which lies

upon beams in the floor Y Y. The top part of the spindle above the bush is square, and goes into a square hole in a strong iron cross, *a b c d*, fig. 3, called the rind; under which, close to the bush, is a round piece of thick leather upon the spindle, which it turns round at the same time that it does the rind. The latter enters into the grooves in the under surface of the running mill-stone G, fig. 2, and thus turns it round along with the trundle E, by means of the cog-wheel D. In the middle of the upper mill-stone is a large hole called the eye, through which the middle part of the rind and upper part of the spindle may be seen: the ends being hid in the grooves below the stone. The end T of the bridge-tree T S, which supports the upper mill-stone G upon the spindle, is fixed into a hole in the wall; and the end S is let into the beam Q R, called the brayer; one end R of which remains fixed in a mortise, while the other end Q hangs by a strong iron rod P, which goes through the floor Y Y, and has a screw-nut on its top O; by the turning of which nut the end Q of the brayer is raised or depressed at pleasure, along with the bridge-tree T S and upper mill-stone. Thus the upper mill-stone may be raised as high from the under one, or let down as close to it as the miller pleases; by which means the meal or flour is made either coarse or fine at pleasure. The upper mill-stone G is enclosed in a round box H, which leaves a vacant space of about an inch all round. On the top of this box stands a frame for holding the hopper *k k*, at which hangs the shoe I, by two lines fastened to the hinder part of it, fixed upon hooks in the hopper, and by one end of the string K to the fore part of it at *i*, the other end being twisted round the pin L. As the pin is turned one way the string draws up the shoe closer to the hopper, and so lessens the aperture between them; and, as the pin is turned the other way, it lets down the shoe, and widens the aperture. If it be drawn quite up to the hopper, no corn can fall out from the latter into the mill, and the quantity will be greater or less as the shoe is farther from the hopper or nearer to it. This happens by reason of the hopper being open at bottom, and the shoe at the forepart towards the end *i* over the middle of the eye of the mill-stone. There is also a square hole in the top of the spindle, in which is put the feeder *e*, fig. 3. Thus the shoe is shaken three times in each revolution, and the corn runs constantly down from the hopper through the shoe into the eye of the mill-stone, where it falls upon the top of the rind, and, by the motion of that and of the leather beneath, is introduced betwixt the stones, and by the violent motion of the upper one acquires a centrifugal force; and, proceeding gradually from the eye of the mill-stone towards the circumference, is thrown at last out in flour, at the hole called the eye of the mill.

Some degree of nicety is requisite in feeding the mill; for, if too great a quantity be poured into it, the stones are separated from each other more than they ought to be, and their motion is also impeded; while, on the other hand, if it be fed too slowly, the stone moves with too great velocity, and the attrition of the two is apt to make them strike fire. This matter is regulated by turning the pin L backwards or forwards as the miller thinks proper. Sometimes, where plenty of water can be had, there are two trundles applied to the cog-wheel by means of a single large one turned immediately by the perpendicular cog-wheel, and carrying round with it a horizontal cogged wheel; on each side of which are placed the smaller trundles abovementioned, carrying the stones. In like manner the water-wheel may be made to drive fanners, bolting-mills, &c.; but it must always be remembered, that, by complicating machinery to a great degree, it becomes more ready to give way; and the frequent reparation of which it stands in need will, by the delay of business, be found at last more expensive than if separate machines had been used.

The wind-mill is furnished with an apparatus similar to the water-mill, but necessarily differs in the external apparatus for applying the power. This is done by means of the two arms A B and C D fig. 4, intersecting each other at right angles in E, and passing through the axis E F, and about thirty-two feet in length. On these yards are placed two sails or vanes, in the shape sometimes of parallelograms, and sometimes of trapeziums, with parallel bases; the greater whereof H I is about six feet, and the length of the smaller F G is determined by radii drawn from the centre E to I and H.

As the direction of the wind is very uncertain, it becomes necessary to have some contrivance for turning the sails towards it, to receive its force in whatever way it may turn; and for this purpose two general methods are in use. In the one, the whole machine is sustained upon a moveable arbor or axis, perpendicular to the horizon, and which is supported by a strong stand or foot very firmly fixed in the earth; and thus, by means of a lever, the whole machine may be turned round as occasion requires. In the other method, only the roof, which is circular, can be turned round by means of a lever and rollers, upon which the circular roof moves. This last kind of wind-mill is always built of stone, in the form of a round turret, having a large wooden ring on the top of it, above which, the roof, which must likewise be of wood, moves upon rollers, as has been already mentioned. To effect this motion the more easily, the wooden ring, which lies on the top of the building, is furnished with a groove, at the bottom of which are placed a number of brass truckles at certain distances, and within the groove is placed another ring, by which the whole roof is supported. The beams *a b* and *a e* are connected with the moveable ring, and a rope is fastened to the beam *a b* in *b*, which at the other extremity is fitted to a windlass or axis in peritrochio; and this rope being drawn through the iron hook G, and the windlass turned round, the sails and roof will be turned round also, in order to catch the wind in any direction. Both these methods of construction have their advantages and disadvantages. The former is the least expensive, as the whole may be made of wood, and of any form that is thought proper; while the other requires a costly building of stone; and, the roof

being round, the building must also be so, while the other can be made of any form, but has the inconvenience of being liable to be carried off altogether by a very high wind.

Plate III. fig. 5, shows the internal mechanism of a wind-mill. A H O is the upper room; H *o* Z the lower one; A B the axle-tree passing through the mill; S T V W the sails covered with canvass set obliquely to the wind, and turning round in the order of the letters. C D is the cog-wheel, having about forty-eight cogs *a*, *a*, *a*, &c., which carry round the lantern E F, having eight or nine trundles *c*, *c*, *c*, &c., along with the axis G N. I K is the upper mill-stone, L M the lower one; O R is the bridge supporting the axis or spindle G N, which rests upon the beams *c d*, X Y, wedged up at *c*, *d*, and X: Z Y is the lifting tree, which stands upright; *a b* and *e f* are levers, having Z and *e* as centres of motion; *f g h i* is a cord, with a stone *i* wound about the pins *g* and *h*, and which thus serves as a balance or counterpoise. The spindle *t* N is fixed to the upper mill-stone I K by means of a piece of iron called the rind, and fixed in the lower side of the stone, the whole weight of which rests upon a hard stone fixed in the bridge Q R at N. The trundle E F and axis G may be taken away; for it rests its lower part by *t* in a square socket, and the top runs in the edge of the beam *w*. By bearing down the end of the lever *f e* we raise *b*, which raises also Z Y, and this raises Y X, which lifts up the bridge Q R, with the axis N G, and the upper stone I K; so tha. by this contrivance the stones may, as in a water-mill, be set at any distance. The lower stone is fixed upon strong beams, and is broader than the upper one; the flour being conveyed through the tunnel *n o* into a chest. P is the hopper into which the corn is put, and which runs along the spout *r* into the hole *t*, and so falls between the stones, where it is ground. The square axis G *t* shakes the spout *r* as it turns round, and makes the corn run out; *r* is a string going round the pin *s*, which serves to bring the spout nearer or let it go farther from the axis, and thus makes the corn to run faster or slower, according to the velocity of the wind. If the wind be very strong, only part of the sails S, T, V, W, is covered, or perhaps only one-half of the two opposite sails. Another cog-wheel B is placed towards the end B of the axle tree, with a trundle and mill-stones like those already described; so that when the wind is strong the mill may do twice the business it ordinarily does. When only one pair is to grind, the trundle E F and axis G *t* are taken out from the other; *x y l* is a girt of pliable wood, fixed at the end *x*; and the other end *l* is tied to the lever *k m*, moveable about *k*; and the end *m*, being put down, draws the girt *x y l* close to the cog-wheel; and thus the motion of the mill may be stopped at pleasure; *p q* is a ladder for ascending to the higher part of the mill; and the corn is drawn up by a ·ope rolled about the axis A B.

In all mills it is necessary that a considerable power be employed in order to accomplish the intended purpose. Water is the most common power, and indeed the best, as being the most constant and equable; while wind comes at some times with great violence, and at others is totally gone. Mills may also be moved by the force of steam, as were the Albion mills at London; but the expense of fuel must undoubtedly prevent this mode of constructing mills from ever becoming general. In all cases it is absolutely necessary to make the most of the power that we can, by making it act to the greatest advantage. Hence the best methods of constructing water and wind-mills have been investigated by those who were most conversant in the principles of mechanics; and so difficult has been the investigation, that the principles are not yet settled absolutely without dispute.

In the fifty-first volume of the Philosophical Transactions, Mr. Smeaton has considered at great length the best methods of constructing all these mills from machines and models made on purpose; but, conscious of the inferiority of models to actual practice, did not venture to give his opinion without having seen them actually tried, and the truth of his doctrines established by practice.

Having described the machines and models used for making his experiments, he observes that, with regard to power, it is most properly measured by the raising of a weight: viz. if the weight raised be multiplied by the height to which it can be raised in a given time, the product is the measure of the power raising it; and, of consequence, all those powers are equal whose products made by such multiplication are equal; for if a power can raise twice the weight to the same height, or the same weight to twice the height, in the same time that another can, the former power will be double the latter; but if a power can only raise half the weight to double the height, or double the weight to half the height, in the same time that another can, the two powers are equal. This, however, must be understood only of a slow and equable motion, without acceleration or retardation; for if the velocity be either very quickly accelerated or retarded, the vis inertiæ, in our author's opinion, will produce an irregularity.

'To compute the effects of water-wheels exactly, it is necessary to know, in the first place, what is the real velocity of the water which impinges on the wheel; 2. The quantity of water expended in a given time; and, 3. How much o. the power is lost by the friction of the machinery.

1. With regard to the velocity of the water, Mr. Smeaton determined by experiments, with the machinery described in the volume referred to, that with a head of water fifteen inches in height, the velocity of the wheel is 8·96 feet in a minute. The area of the head being 105·8 inches; this, multiplied by the weight of a cubic inch of water, equal to ·579 of an ounce avoirdupois, gives 61·26 ounces for the weight of as much water as is contained in the head, upon one inch in depth; and by farthei calculations, derived from the machinery made use of, he computes that 264·7 lbs. of water descend in a minute through the space of fifteen inches. The power of the water, therefore, to produce mechanica. effects in this case will be $264 \cdot 7 \times 15$, or 3970. From the result of the experiment, however, it

appeared that a vast quantity of the power was lost; the effect being only to raise 9·375 lbs. to the height of 135 inches; so that the power was to the effect as 3970 to $9·375 \times 135 = 1266$, or as 10 to 3·18.

This, according to our author, must be considered as the greatest single effect of water upon an undershot wheel, where the water descends from a height of fifteen inches; but, as the force of the current is not by any means exhausted, we must consider the true proportion betwixt the power and effect to be that betwixt the quantity of water already mentioned and the sum of all the effects producible from it. This remainder of power, it is plain, must be equal to that of the velocity of the wheel itself, multiplied into the weight of the water. In the present experiment, the circumference of the wheel moved with the velocity of 3·123 feet in the second, which answers to a head of 1·82 inches, and this height being multiplied by 264·7, the quantity of water expended in a minute gives 481 for the power of the water after it has passed the wheel; and hence the true proportion betwixt the power and the effect will be as 3849 to 1266, or as 11 to 4. These calculations are founded upon the known maxim in hydrostatics, that the velocity of spouting water is nearly the same with that which a heavy body would acquire by falling from a height equal to that of the reservoir, and is proved by the rising of jets nearly to the height of their reservoirs.

As the wheel revolved eighty-six times in a minute, the velocity of the water must be equal to eighty-six circumferences of the wheel; which, according to the dimensions of the apparatus used by Mr. Smeaton, was as 86 to 30, or as 20 to 7. The greatest load with which the wheel could move was 9 lbs. 6 oz.; and by 12 lbs. it was entirely stopped. Whence our author concludes, that the impulse of the water is more than double of what it ought to be according to theory: but this he accounts for by observing, that in his experiment the wheel was placed not in an open river, where the natural current, after it has communicated its impulse to the float, has room on all sides to escape, as the theory supposes, but in a conduit, to which the float being adapted, the water cannot otherwise escape than by moving along with the wheel. It is observable, that a wheel working in this manner, as soon as the water meets the float, receiving a sudden check, it rises up against the float like a wave against a fixed object; insomuch that, when the sheet of water is not a quarter of an inch thick before the float, yet the sheet will act upon the whole surface of a float whose height is three inches; and consequently, were the float no higher than the thickness of the sheet of water, as the theory also supposes, a great part of the force would be lost by the water dashing over the float.

Mr. Smeaton next proceeds to give tables of the velocities of wheels with different heights of water; and from the whole deduces the following conclusions:—1. The virtual or effective head being the same, the effect will be nearly as the quantity of water expended. 2. The expense of water being the same, the effect will be nearly as the height of the virtual or effective head. 3. The quantity of water expended being the same, the effect is nearly as the square of the velocity. 4. The aperture being the same, the effect will be nearly as the cube of the velocity of the water. Hence, if water passes out of an aperture in the same section, but with different velocities, the expense will be proportional to the velocity; and therefore, if the expense be not proportional to the velocity, the section of the water is not to the same. 5. The virtual head, or that from which we are to calculate the power, bears no proportion to the head of water; but when the aperture is larger, or the velocity of the water less, they approach nearer to a coincidence; and consequently, in the large openings of mills and sluices, where great quantities of water are discharged from moderate heads, the head of water, and the virtual head determined from the velocity, will nearly agree, which is also confirmed by experience. 6. The most general proportion betwixt the power and effect is that of 10 to 3; the extremes 10 to 3·2, and 10 to 2·8. But it is observable that, where the power is greatest, the second term of the ratio is greatest also; whence we may allow the proportion subsisting in great works to be as 3 to 1. 7. The proportion of velocity between the water and wheel is in general about 5 to 2. 8. There is no certain ratio between the load that the wheel will carry at its maximum, and what will totally stop it; though the proportions are contained within the limits of 20 to 19, and 20 to 15; but as the effect approaches nearest to the ratio of 20 to 15, or of 4 to 3 when the power is greatest either by increase of velocity or quantity of water, this seems to be the most applicable to large works; but as the load that a wheel ought to have, in order to work to the best advantage, can be assigned by knowing the effect that it ought to produce, and the velocity it ought to have in producing it, the exact knowledge of the greatest load it will bear is of the least consequence in practice.

Mr. Smeaton, after having finished his experiments on the undershot mills, reduced the number of floats, which were originally 24, to 12; which caused a diminution in the effect, by reason that a greater quantity of water escaped between the floats and the floor than before; but on adapting to it a circular sweep, of such a length that one float entered into the curve before the other left it, the effect came so near that of the former as not to give any hopes of advancing it by increasing the number of floats beyond twenty-four in this particular wheel.

He next proceeds to examine the power of water when acting by its own gravity in turning an overshot wheel: 'in reasoning without experiment,' says he, 'one might be led to imagine that however different the mode of application is, yet whenever the same quantity of water descends through the same perpendicular space, the natural effective power would be equal, supposing the machinery free from friction, equally calculated to receive the full effect of the power, and to make the most of it: for if we suppose the height of a column of water to be thirty inches, and resting upon a base or aperture of

one inch square, every cubic inch of water that departs therefrom will acquire the same velocity or momentum, from the uniform pressure of thirty cubic inches above it, that one cubic inch let fall from the top will acquire in falling down to the level of the aperture; one would therefore suppose that a cubic inch of water, let fall through a space of thirty inches, and there impinging upon another body, would be capable of producing an equal effect by collision, as if the same cubic inch had descended through the same space with a slower motion, and produced its effects gradually. But however conclusive this reasoning may seem, it will appear, in the course of the following deductions, that the effect of the gravity of descending bodies is very different from the effect of the stroke of such as are non-elastic, though generated by an equal mechanical power.

Having made such alterations in his machinery as were necessary for overshot wheels, our author next gives a table of experiments with the apparatus so altered. In these the head was six inches, and the height of the wheel twenty-four inches; so that the whole descent was thirty inches; the quantity of water expended in a minute was 96⅔ lbs.; which, multiplied by thirty inches, gives the power = 2900: and, after making the proper calculations, the effect was computed at 1914; whence the ratio of the power to it comes to be nearly 3 to 2. If, however, we compute the power from the height of the wheel only, the power will be to the effect nearly as 5 to 4.

From another set of experiments the following conclusions were deduced:—

1. The effective power of the water must be reckoned upon the whole descent: because it must be raised to that height in order to be able to produce the same effect a second time. The ratios between the powers so estimated and the effects at a maximum, differ nearly from 4 to 3, and from 4 to 2. Where the heads of water and quantities of it expended are the least, the proportion is nearly from 4 to 3; but, where the heads and quantities are greatest, it comes nearer to that of 4 to 2: so that by a medium of the whole the ratio is nearly as 3 to 2. Hence it appears that the effect of overshot wheels is nearly double to that of undershot ones; the consequence of which is, that non-elastic bodies, when acting by their impulse of collision, communicate only a part of their original impulse, the remainder being spent in changing their figure in consequence of the stroke. The ultimate conclusion is, that the effects as well as the powers are as the quantities of water and perpendicular heights multiplied together respectively.

2. By increasing the head it does not appear that the effects are at all augmented in proportion; for, by raising it from three to eleven inches, the effect was augmented by less than one-seventh of the increase of perpendicular height. Hence it follows, that the higher the wheel is, in proportion to the whole descent, the greater will be the effect; because it depends less upon the impulse of the head, and more upon the gravity of the water in buckets: and, if we consider how obliquely the water issuing from the head must strike the buckets, we shall not be at a loss to account for the little advantage that arises from the impulse thereof, and shall immediately see of how little consequence this is to the effect of an overshot wheel. This however, as well as other things, must be subject to limitation; for it is necessary that the velocity of the water should be somewhat greater than the wheel, otherwise the latter will not only be retarded by the striking of the buckets against the water, but some of the power will be lost by the dashing of the water over the buckets.

3. To determine the velocity which the circumference of the wheel ought to have, in order to produce the greatest effect, Mr. Smeaton observes that the more slowly any body descends by the force of gravity, when acting upon any piece of machinery, the more of that force will be spent upon it, and consequently the effect will be the greater. If a stream of water falls into the bucket of an overshot wheel it will be there retained till the wheel discharges it by moving round, and, of consequence, the slower the wheel moves, the more water it will receive; so that what is lost in velocity is gained by the greater pressure of water upon the buckets. From the experiments, however, it appears that, when the wheel made about twenty turns in a minute, the effect was greatest; when it made only eighteen and a quarter, the motion was irregular; and, when loaded so as not to admit its turning eighteen times, the wheel was overpowered with the load. When it made thirty turns, the power was diminished by about one-twentieth; and, when the number of turns was increased to forty, it was diminished by one-fourth. Hence we see that in practice the velocity of the wheel should not be diminished farther than what will procure some solid advantage in point of power; because, ceteris paribus, the buckets must be larger as the motion is slower; and, the wheel being more loaded with water, the stress will be proportionably increased upon every part of the work. The best velocity for practice therefore will be that when the wheel made thirty turns in a minute, which is little more than three feet in a second. This velocity is applicable to the highest overshot wheels as well as the lowest. Experience however determines, that high wheels may deviate further from this rule before they will lose their power, by a given aliquot part of the whole, than low ones can be permitted to do; for a wheel of twenty-four feet high may move at the rate of six feet per second; while our author has seen one of thirty-three feet high move very steadily and well with a velocity of little more than two feet. The reason of this superior velocity, in the twenty-four feet wheel, may probably be owing to the small proportion that the head requisite to give the proper velocity to the wheel bears to the whole height.

4. The maximum load for an overshot wheel is that which reduces the circumference of the wheel to its proper velocity; which is known by dividing the effect it ought to produce in a given time by the space intended to be described by the circumference of the wheel in the same time: the quotient will be the resistance overcome at the circumference of the wheel, and is equal to

the load required, including the friction and resistance of the machinery.

5. The greatest velocity that an overshot wheel is capable of depends jointly upon the diameter or height of the wheel and the velocity of falling bodies; for it is plain that the velocity of the circumference can never be greater than to describe a semi-circumference, while a body let fall from the top describes the diameter, nor even quite so great; as the difference in point of time must always be in favor of that which falls through the diameter. Thus, supposing the diameter of the wheel to be sixteen feet and an inch in diameter, a heavy body would fall through this space in one second; but such a wheel could never arrive at this velocity, or make one turn in two seconds, nor could an overshot wheel ever come near it; because, after it has acquired a certain velocity, great part of the water is prevented from entering the buckets, and part is thrown out again by the centrifugal force; and, as these circumstances have a considerable dependence upon the form of the buckets, it is impossible to lay down any general rule for the velocity of this kind of wheels.

6. Though in theory we may suppose a wheel to be made capable of overcoming any resistance whatever, yet, as in practice it is necessary to make the wheel and buckets of some certain and determinate size, we always find that the wheel will be stopped by such a weight as is equal to the effort of the water in all the buckets of a semi-circumference put together. This may be determined from the structure of the buckets themselves; but, in practice, an overshot wheel becomes unserviceable long before this time; for, when it meets with such an obstacle as diminishes its velocity to a certain degree, its motion becomes irregular; but this never happens till the velocity of the circumference is less than the two feet per second, when the resistance is equable.

7. From the above observations we may easily deduce the force of water upon breast-wheels, &c. But, in general, all kinds of wheels, where the water cannot descend through a given space unless the wheel moves with it, are to be considered as overshot wheels; and those which receive the impulse or shock of the water, whether in an horizontal, oblique, or perpendicular direction, are to be considered as undershots. Hence a wheel, in which the water strikes at a certain point below the surface of the head, and after that descends in the arch of a circle, pressing by its gravity upon the wheel, the effect of such a wheel will be equal to that of an undershot whose head is equal to the difference of level between the surface of the water in the reservoir and the point where it strikes the wheel, added to that of an overshot whose height is equal to the difference of level between the point where it strikes the wheel and the level of the tail-water.

In the sixty-sixth volume of the Transactions, Mr. Smeaton considers some of the causes which have produced disagreements and disputes among mathematicians upon this subject. He observes, that soon after Sir Isaac Newton had given his definition, 'that the quantity of motion is the measure of the same, arising from the velocity and quantity of matter conjointly,' it was controverted by his contemporary philosophers. They maintained that the measure of the quantity of motion should be estimated by taking the quantity of matter and the square of the velocity conjointly. On this subject he remarks that, from equal impelling powers acting for equal intervals of time, equal augmentations of velocity are acquired by given bodies when they are not resisted by a medium. Thus a body descending one second by the force of gravity, passes through a space of sixteen feet and an inch; but at the end of that time it has acquired a velocity of thirty-two feet two inches in a second; at the end of two seconds it has acquired one that would carry it through sixty-four feet four inches in a second. If, therefore, in consequence of this equal increase of velocity, we define this to be a double quantity of motion generated in a given time in a certain quantity of matter, we come near to Sir Isaac's definition; but, in trying experiments upon the effects of bodies, it appears that when a body is put in motion, by whatever cause, the impression it will make upon an uniformly resisting medium, or upon uniformly yielding substances, will be as the mass of matter of the moving body multiplied by the square of its velocity. The question, therefore, properly is, whether these terms, the quantity of motion, the momenta, or forces, of bodies in motion, are to be esteemed equal, double, or triple, when they have been generated by an equable impulse acting for an equal, double, or triple time? or that it should be measured by the effects being equal, double, or triple, in overcoming resistances before a body in motion can be stopped? For, according to the meaning we put upon these words, the momenta of equal bodies will be as the velocities or squares of the velocities of the moving bodies.

Undershot wheels had been greatly preferred by M. Belidor to those of any other construction. He had even concluded, that water applied in this way will do more than six times the work of an overshot wheel; While Dr. Desaguliers, in overthrowing Belidor's proposition, asserted that an overshot wheel would do ten times the work of an undershot wheel with an equal quantity of water. Between these two celebrated authors, therefore, there is a difference of no less than sixty to one. In consequence of such enormous disagreement, Mr. Smeaton began the experiments above described. From them, besides the positions already deduced, it appears that, where the velocity of water is double, the adjutage or aperture of the sluice remaining the same, the effect is eight times; that is, not as the square, but as the cube of velocity. In the other conclusion of Desaguliers and Maclaurin, the error was no less; for, from thence it would follow, that by means of the wheel only $\frac{4}{27}$ths of the water expended would be raised back again to the height of the reservoir from which it descended, exclusive of the friction, which would still diminish the quantity; but from Mr. Smeaton's experiments it appears that in some cases upwards of one-fourth had been raised. In large works the effects had been still greater, approaching in an undershot wheel to one-half, and in an overshot one to the whole; which

would be the limit, if it were possible to remove the friction and resistance of the air. The velocity of the wheel also, which, according to the conclusions of M. Parent and Dr. Desaguliers, amounted to no more than one-third of the velocity of the water, varies, according to Mr. Smeaton, between one-third and one-half. But in all great works the maximum lies much nearer to one-half than a third; the former appearing to be the true maximum, if all friction, resistance of the air, and scattering of water could be avoided.

To make these matters plain to mechanics, and to prevent them from running into practical errors, in consequence of a fallacious theory, Mr. Smeaton, in the year 1759, instituted another set of experiments; the immediate object of which was to determine what proportion or quantity of mechanical power is expended in giving the same body different degrees of velocity. Having constructed a proper apparatus for the purpose, and with it made a number of experiments, he concludes, 'that time, properly speaking, has nothing to do with the production of mechanical effects, otherwise than as by equally flowing it becomes a common measure; so that whatever mechanical effect is found to be produced in a given time, the uniform continuance of the action of the same mechanical power will in a double time produce twice that effect. A mechanical power, therefore, properly speaking, is measured by the whole of its mechanical effects produced, whether that effect be produced in a greater or less time: thus, having treasured up 1000 tons of water, which I can let out upon the overshot wheel of a mill, and descending through a perpendicular of twenty feet; this power, applied in a proper manner, will grind a certain quantity of corn in an hour: but supposing the mill to be capable of receiving a greater impulse with as great disadvantage as a less; then, if the corn be let out twice as fast, the same quantity of corn will be ground in half an hour, the whole of the water being likewise expended in that time. What time has therefore to do in the case is this: let the rate of doing the business, or producing the effect, be what it will; if this rate is uniform, when I have found by experiment what is done in a given time, then, proceeding at the same rate, twice the effect will be produced in twice the time, on a supposition that I have a supply of mechanic power to go on with. Thus, 1000 tons of water descending through twenty feet perpendicular, being, as has been shown, a given mechanic power, let it be expended at what rate it will; if, when this is expended, we are to wait another hour till an equal quantity can be procured, then we can only expend twelve such quantities in twenty-four hours. But if, while the 1000 tons of water are expending in one hour, the same quantity is renewed, we can then expend twenty-four such in twenty-four hours, or go on without intermission. The product or effect will then be in proportion to time, which is the common measure; but the quantity of mechanic power arising from the flow of the two rivers, compared by taking an equal portion of time, is double in the one to the other; though each has a mill that, when going, will grind an equal quantity of corn in an hour.'

Mr. Ferguson, in his directions to mill-wrights, has adopted the maxim which Mr. Smeaton condemns as erroneous, viz. that, when the velocity of the wheel is but one-third of that of the water, it then acts to the greatest advantage. He adds that the mill-stone ought to make about sixty turns in a minute; for when it makes only forty or fifty turns it grinds too slowly; and, when more than seventy, it heats the meal too much, and cuts the bran so small that a part of it mixes with the meal, and cannot be separated from it by any means. The utmost perfection of millwork, therefore, according to this author, lies in making the train so that the mill-stones shall make about sixty turns in a minute, when the wheel moves with one-third of the velocity of the water. To accomplish this, he lays down the following rules:—1. Measure the perpendicular height of the fall of water above the middle of the aperture, where it is let out to act by impulse against the float-boards on the lower side of the undershot wheel. 2. Multiply this constant number 64·2882 by the height of the fall in feet, and extract the square root of the product, which will give the number of feet that the water moves in a second. 3. The velocity of the floats of the wheel is equal to one-third of the velocity of the water just now found. 4. Divide the circumference of the wheel by the velocity of its floats, and the quotient will be the number of seconds in one turn of the great water wheel, on whose axis the cog-wheel that turns the trundle is fixed. 5. Divide sixty by the number of seconds in a turn of the water-wheel, and the quotient will be the number of turns it makes in a minute. 6. By this number of turns divide sixty, the number of turns that a mill-stone ought to have in a minute; the quotient is the number of turns that the mill-stone ought to make for every one of the large wheel. 7. Then, as the number of turns required of the mill-stone in a minute is to the number of turns of the cog-wheel in a minute; so must the number of cogs in the wheel be to the number of staves in the trundle on the axis of the mill-stone, in the nearest whole number that can be found. On these principles Mr. Ferguson has constructed the following table, for the sake of such as have occasion to construct mills, and are not willing or able to make particular calculations:—

Height of the fall of water.	Velocity of the fall of water per second.		Velocity of the wheel per second.		Revolutions of the wheel per minute.		Revolutions of the mill-stone for one of the wheel.		Cogs in the wheel, and staves in the trundle.		Revolutions of the mill-stone per minute, by these staves and cogs.	
Feet.	Feet.	100 parts of a foot.	Feet.	100 parts of a foot.	Revolutions	100 parts of a rev.	Revolutions	100 parts of a rev.	Cogs.	Staves.	Revolutions	100 parts of a rev.

For the practical construction of water mills, Mr. Imison has laid down the following rules. To find the velocity or force of any moderate stream of water; let it be obstructed by a dam, in such a manner as to force the whole stream into a spout, by which it may be conveyed into a large vessel or reservoir. Measure then the quantity of water which falls into the reservoir in one second or minute; and, multiplying by the number of seconds or minutes in an hour, we have the whole force of the stream of water per hour. In streams which are too large to be measured in this way the velocity is determined (though, we must own, in a vague manner) by that of straw or other light body floating down it; and calculations may be made accordingly. Mr. Imison differs materially from Mr. Ferguson in the number of revolutions which a mill-stone ought to make in a minute; the latter being of opinion that sixty revolutions of a mill-stone in a minute are sufficient, while Mr. Imison requires 120; though he agrees with him that the velocity of the wheel should be only one-third of that of the water. The mill-stone, according to Mr. Ferguson, ought to be five feet in diameter; but Mr. Imison makes it only four feet and a half.

To construct a mill by this table, find the height of the fall of water in the first column, and against that height, in the sixth column, you have the number of cogs in the wheel, and staves in the trundle, for causing the mill-stone, four feet six inches diameter, to make about 120 revolutions in a minute, as nearly as possible, when the wheel goes with one-third part of the velocity of the water. And it appears, by the seventh column, that the number of cogs in the wheel and staves in the trundle are so near the truth for the required purpose, that the least number of revolutions of the mill-stone in a minute is 118, and the greatest number never exceeds 121; which, according to our author, is the velocity of the best mills he had seen.

With regard to the mere mechanical part, our author observes, that an overshot wheel acts with greater power than a breast or undershot wheel; so that where there is a considerable descent, and only a small quantity of water, the overshot wheel ought always to be made use of. Where the water runs only upon a little declivity, it can act but slowly upon the under part of the wheel; in which case the motion of the wheel will be very slow: the float boards therefore ought to be very long, though not high, that a large body of water may act upon them; so that what is wanting in velocity may be made up in power: in which case the cog-wheel may have a greater number of cogs, in proportion to the staves of the trundle, in order to give the mill-stone a sufficient degree of velocity.

In the construction of wind-mills Mr. Smeaton has been at no less pains to explain the principles than in those which go by water. For this purpose he constructed a machine, of which a particular description was given in the fifty-first volume of the Philosophical Transactions. The general principle of this was, that by means of a determinate weight it carried round an axis with a horizontal arm, upon which were four small

moveable sails. Thus the sails met with a constant and equable blast of air; and, as they moved round, a string with a weight affixed to it was wound about their axis, and thus showed what kind of size or construction of sails answered the purpose best. With this machine a great number of experiments were made; the results of which were as follows:—

1. The sails set at the angle with the axis, proposed as the best by M. Parent and other geometricians, viz. 55°, was found to be the worst proportion of any that were tried.

2. When the angle of the sails with the axis was increased from 72° to 75°, the power was augmented in the proportion of 32 to 45; and this is the angle most commonly in use when the sails are planes.

3. Were nothing more requisite than to cause the sails to acquire a certain degree of velocity by the wind, the position recommended by M. Parent would be the best. But if the sails are intended, with given dimensions, to produce the greatest effects possible in a given time, we must, if planes are made use of, confine our angle within the limits of 72° and 75°.

4. The variation of a degree or two, when the angle is near the best, is but of little consequence.

5. When the wind falls upon concave sails, it is an advantage to the power of the whole, though each part separately taken should not be disposed of to the best advantage.

6. From several experiments, on a large scale, Mr. Smeaton has found the following angles to answer as well as any. The radius is supposed to be divided into six parts and one-sixth, reckoning from the centre, and is called 1, the extremity being denoted 6:

No.	Angle with that Axis.	Angle with the Plane of Motion.
1	72°	18°
2	71	19
3	72	18 middle
4	74	16
5	77½	12½
6	83	7 extremity.

7. Having thus obtained the best method of weathering the sails, i. e. the most advantageous manner in which they can be placed, our author's next care was to try what advantage could be derived from an increase of surface upon the same radius. The result was, that a broader sail requires a large angle; and, when the sail is broader at the extremity than near the centre, the figure is more advantageous than that of a parallelogram. The figure and proportion of enlarged sails, which our author determines to be the most advantageous on a large scale, is that where the extreme bar is one-third of the radius or whip (as the workmen call it), and is divided by the whip in the proportion of 3 to 5. The triangular or loading sail is covered with board from the point downward of its height, the rest as usual with cloth. The angles abovementioned are likewise the most proper for enlarged sails; it being found in practice that the sails should rather be too little than too much exposed to the direct action of the wind.

Some have imagined that the more sail the greater would be the power of the windmill, and have therefore proposed to fill up the whole area; and by making each sail a sector of an ellipsis, according to M. Parent's method, to intercept the whole cylinder of wind, in order to produce the greatest effect possible. From our author's experiments, however, it appeared, that when the surface of the sail exceeded seven-eighths of the area, the effect was rather diminished than augmented. Hence he concludes that, when the whole cylinder of wind is intercepted, it cannot then produce the greatest effect, for want of proper interstices to escape. 'It is certainly desirable,' says Mr. Smeaton, 'that the sails of windmills should be as short as possible; but it is equally desirable that the quantity of cloth should be the least that may be, to avoid damage by sudden squalls of wind. The best structure, therefore, for large mills, is that where the quantity of cloth is the greatest that can be in a given circle; on this condition, that the effect holds out in proportion to the quantity of cloth; for otherwise the effect can be augmented in a given degree by a less increase of cloth, upon a larger radius, than would be required if the cloth was increased upon the same radius.'

8. The ratios between the velocities of windmill sails unloaded, and when loaded to their maximum, turned out very different in different experiments, but the most common proportion was 3 to 2. In general it happened, that where the power was greatest, whether by enlargement of the surface of the sails, or an increased velocity of the wind, the second term of the ratio was diminished.

9. The ratios between the least load that would stop the sails, and the maximum with which they would turn, were confined betwixt that of 10 to 8 and 10 to 9; being at a medium about 10 to 8·3, and 10 to 9, or about 6 to 5; though, on the whole, it appeared that, where the angle of the sails or quantity of cloth was greatest, the second term of the ratio was less.

10. The velocity of wind-mill sails, whether unloaded or loaded, so as to produce a maximum, is nearly as the velocity of the wind, their shape and position being the same. On this subject Mr. Ferguson remarks, that it is almost incredible to think with what velocity the tips of the sails move when acted upon by a moderate wind. He has several times counted the number of revolutions made by the sails in ten or fifteen minutes; and, from the length of the arms from tip to tip, has computed that if a hoop of the same size was to run upon plain ground with an equal velocity, it would go upwards of thirty miles in an hour.

11. The load at the maximum is nearly, but somewhat less, than as the square of the velocity of the wind; the shape and position of the sails being the same.

12. The effects of the same sails at a maximum are nearly, but somewhat less than, as the cubes of the velocity of the wind.

13. The load of the same sails at a maximum

is nearly as the squares, and the effect as the cubes of their number of turns in a given time.

14. When sails are loaded so as to produce a maximum at a given velocity, and the velocity of the wind increases, the load continuing the same; then the increase of effect, when the increase of the velocity of the wind is small, will be nearly as the squares of these velocities; but, when the velocity of the wind is double, the effects will be nearly as 10 to 27½; and, when the velocities compared are more than double of that where the given load produces a maximum, the effects increase nearly in a simple ratio of the velocity of the wind. Hence our author concludes that wind-mills, such as the different species for draining water, &c., lose much of their effect by acting against one invariable opposition.

15. In sails of a similar figure and position the number of turns in a given time will be reciprocally as the radius or length of the sail.

16. The load, at a maximum, that sails of a similar figure and position will overcome, at a given distance from the centre of motion, will be as the cube of the radius.

17. The effects of sails of similar position and figure are as the square of the radius. Hence, augmenting the length of the sail, without augmenting the quantity of cloth, does not increase the power; because what is gained by the length of the lever is lost by the slowness of the motion. Hence also, if the sails are increased in length, the breadth remaining the same, the effect will be as the radius.

18. The velocity of the extremity of the Dutch sails, as well as of the enlarged sails, either unloaded, or even when loaded to a maximum, is considerably greater than that of the wind itself. This appears plainly from the observations of Mr. Ferguson, already quoted, concerning the velocity of sails.

19. From many observations of the comparative effects of sails of various kinds, Mr. Smeaton concludes that the enlarged sails are superior to those of the Dutch construction.

Having thus discussed the subject of the common wind-mills with oblique vanes, Mr. Smeaton next proceeds to the consideration of those called horizontal wind-mills, in which it is attempted to make the wind impinge directly upon the wheel, as in the case of water-mills. To set the probable advantage of this scheme in its proper point of view, Mr. S. proceeds in the following manner:—'Let A B, fig. 6, be the section of a plane, in which let the wind blow in the direction C D, with such a velocity as to describe a given space, B E, in a given time, suppose one second; and let A B be moved parallel to itself in the direction C D. Now if the plane A B moves with the same velocity as the wind; that is, if the point B moves through the space B E in the same time that a particle of air would move through it, it is plain that in this case there can be no pressure or impulse of the wind upon the plane; but if the plane moves slower than the wind, so that the point B may move to F, while a particle of air setting out from B would reach E, then B F will express the velocity of the plane; and the relative velocity of the wind and plane would be expressed by the line F E. Let the ratio of F E to B E be given, suppose 2 to 3; let the line A B represent the impulse of the wind upon the plane A B when acting with its whole velocity B E; but, when acting with its relative velocity F E, let its impulse be denoted by some aliquot part of A B, as for instance $\frac{4}{9}$; then will $\frac{4}{9}$ths of the parallelogram A F represent the mechanical power of the plane, that is, $\frac{4}{9}$th A B × $\frac{1}{3}$ B E. Let I N be the section of a plane inclined in such a manner that the base I K of the right-angled triangle I K N may be equal to A B, and the perpendicular N K = B E: let the plane I N be struck by the wind in the direction L M, perpendicular to I K; then, according to the known rules of oblique forces, the impulse of the wind upon the plane I N, tending to move it according to the direction L M or N K, will be denoted by the base I K; and that part of the impulse tending to move it, according to the direction I K, will be expressed by the perpendicular N K. Let the plane I N be moveable in the direction of I K only; that is, the point I in the direction of I K, and the point N in the direction N Q, parallel thereto. Now it is evident that, if the point I moves through the line I K, while a particle of air, setting forwards at the same time from the point N, moves through the line N K, they will both arrive at the point K at the same time; and consequently there can be no pressure or impulse of the particle of air upon the plane I N. Now let I O be to I K as B F to B E; and let the plane I N move at such a rate that the point I may arrive at O, and acquire the position O Q, in the same time that a particle of air would move through the space N K; as O Q is parallel to I N, by the properties of similar triangles it will cut N K in the point P in such a manner that N P will be equal to B F, and P K to F E. Hence it appears that the plane I N, by acquiring the position O Q, withdraws itself from the action of the wind, by the same space N P that the plane A B does by acquiring the position F G; and consequently, from the equality of P K to F E, the relative impulse of the wind P K upon the plane O Q will be equal to the relative impulse of the wind upon the plane F G; and since the impulse of the wind upon A B, with the relative velocity F E, in the direction B E, is represented by $\frac{4}{9}$ A B; the relative impulse of the wind upon the plane I N in the direction N K will, in like manner, be represented by $\frac{4}{9}$ I K; and the impulse of the wind upon the plane I N, with the relative velocity P K in the direction I K, will be represented by $\frac{4}{9}$ N K: and consequently the mechanical power of the plane in the direction I K will be represented by $\frac{4}{9}$ of the parallelogram I Q: that is, $\frac{1}{3}$ I K × $\frac{4}{9}$ N K: that is, from the equality of I K to A B, and N K to B E, we shall have $\frac{4}{9}$ I Q = $\frac{1}{3}$ A B × $\frac{4}{9}$ B E = $\frac{4}{9}$ A B × $\frac{1}{3}$ B E = $\frac{4}{27}$, the area of the parallelogram A F.

'Hence we deduce this general proposition, that all planes, however situated, that intercept the same section of the wind, and have the same relative velocity in regard to the wind, when reduced into the same direction, have equal powers to produce the same mechanical effects. For what is lost by the obliquity of the

impulse is gained by the velocity of the motion. Hence it appears that an oblique sail is under no disadvantage in respect of power, compared with a direct one; except what arises from a diminution of its breadth, in regard to the section of the wind; the breadth I N being by obliquity reduced to I K.

'The disadvantage of horizontal wind-mills, therefore, does not consist in this, that each sail, when directly exposed to the wind, is capable of a less power than an oblique one of the same dimensions; but that, in a horizontal wind-mill, little more than one sail can be acting at once: whereas, in the common wind-mill, all the four act together; and therefore, supposing each vane of a horizontal wind-mill to be of the same size with that of a vertical one, it is manifest that the power of a vertical mill will be four times as great as that of a horizontal one, let the number of vanes be what we will. This disadvantage arises from the nature of the thing; but if we consider the further disadvantage that arises from the difficulty of getting the sails back again against the wind, &c., we need not wonder if this kind of mill is in reality found to have not above one-eighth or one-tenth of the power of the common sort: as has appeared in some attempts of this kind.'

The regulation of the velocity of a mill is a matter of very great importance to preserve a uniformity of motion, either when the force of the first mover is fluctuating, or when the resistance, or work of the mill, varies in its degree: either or both of these causes will occasion the mill to accelerate or diminish its velocity; and in many instances it will have a very injurious effect upon the operations of the mill. Thus, in a mill for spinning cotton, wool, flax, &c., driven by a water-wheel, are a multiplicity of movements, many of which are occasionally disengaged, in different parts of the mill, for various purposes. This tends to diminish the resistance to the first mover, and the whole mill accelerates. Or, on the other hand, the head of water, which drives the wheel, may be liable to rise and fall suddenly, from many causes to which great and rapid rivers are subject, and cause similar irregularities in the speed of the wheel. For such cases judicious mechanics have adopted contrivances, or regulators, which counteract all these causes of irregularity; and a large mill, so regulated, will move like a clock, with regard to its regularity of velocity. These regulators are usually called governors, the application of which is most conspicuous in the steam engine, when that machine is applied to manufacturing purposes.

Let A B, fig. 7, be a vertical axis, which is made to revolve by the bevelled wheel A, acted on by the other parts of the machinery, and so that it always revolves with a velocity proportional to that of the fly-wheel. Two heavy balls C C′ are attached to metal rods, which work on a pivot at B, so that they are capable of receding from the axis A B. As they recede from the axis, the joints D D′ recede from one another, and the joint E is drawn down. This joint E is connected with the end of a lever, or a system of levers, the action of which we shall presently explain.

Now, by the revolution of the spindle or axis A B, the balls C C′ acquire an obvious tendency to fly off from the axis, and this tendency is resisted by their weight; so that, when the instrument is revolving with a certain velocity, the balls will remain suspended. The property from which this apparatus derives its whole efficacy is, that at whatever distance or in whatever position the balls remain suspended, and neither move to or from the axis, the spindle A B must be revolving with the same velocity. A greater velocity would cause the balls to fly, and a less velocity would cause them to fall towards the axis.

If the action of the levers with which the joint E is connected be directed upon the first mover in such a manner that its energy is diminished when E is depressed, and increased when E is elevated, it is plain that the uniformity of velocity which is sought may be obtained. Let us suppose that the levers on which E works communicate with a valve which admits steam to the piston of a steam-engine to which this governor is applied; and suppose that, when E is raised, and the balls C C′ rest in their seats, the valve is fully open, so as to allow the steam to flow in a full stream to the piston; but that according as E is depressed the levers gradually close the valve, so as to admit the steam in a constantly diminished quantity. Now suppose that the engine has been working twenty printing presses, and that the action of ten of them is suddenly suspended. The engine thus loses half its load, and would, if the same power of steam continued to be admitted, move with about twice its former velocity. But the moment an increased velocity is perceived in the machine, the balls C C′ recede from the axis, draw down the joint E, partially close the valve, and check the supply of steam to the cylinder. The impelling power is thus diminished; and, if it be diminished in exactly the same degree as the load, the machine will move with its former velocity; but if it should, at first, be more diminished, the velocity will be less than its former velocity, and the balls will again move towards the axis and open the valve, and will, at length, settle into that position in which the steam admitted to the cylinder is exactly proportioned to the load on the machine; and the proper velocity will thus be restored.

In the employment of machinery, it is evidently of great importance to be provided with an easy and ready method for discovering at all times whether the motion of the machine is quicker or slower than what is known to be best adapted for the object in view. This advantage is derived from the tachometer, an instrument contrived by Mr. Donken, for which he was rewarded by the Society for the Encouragement of Arts, &c., with their gold medal.

A front view of the tachometer is represented in fig. 8, and a side view in fig. 9. X Y Z, fig. 8, is the vertical section of a wooden cup, made of box, which is drawn in elevation at fig. 9. The whiter parts of the section in fig. 8 represent what is solid, and the dark parts what is hollow. This cup is filled with mercury up to the level L I., fig. 8. Into the mercury is immersed the lower part of the upright glass tube

A B, which is filled with colored spirits of wine, and open at both ends, so that some of the mercury in the cup enters at the lower orifice, and, when every thing is at rest, supports a long column of spirits, as represented in the figure. The bottom of the cup is fastened by a screw to a short vertical spindle D; so that, when the spindle is whirled round, the cup, whose figure is a solid of revolution, revolves at the same time round its axis, which coincides with that of the spindle.

In consequence of this rotation, the mercury in the cup acquires a centrifugal force, by which its particles are thrown outwards, and that with the greater intensity, accordingly as they are more distant from the axis, and according as the angular velocity is greater. Hence, on account of its fluidity, the mercury rises higher and higher as it recedes from the axis, and consequently sinks in the middle of the cup; this elevation at the sides and consequent depression in the middle increasing always with the velocity of rotation. Now the mercury in the tube, though it does not revolve with the cup, cannot continue higher than the mercury immediately surrounding it, nor indeed so high, on account of the superincumbent column of spirits. Thus the mercury in the tube will sink, and consequently the spirits also; but, as that part of the tube which is within the cup is much wider than the part above it, the depression of the spirits will be much greater than that of the mercury, being in the same proportion in which the square of the larger diameter exceeds the square of the smaller.

Let us now suppose, that, by means of a cord passing round a small pulley F, and the wheel G, or in any other convenient way, the spindle D is connected with the machine whose velocity is to be ascertained. In forming this connexion we must be careful to arrange matters so that, when the machine is moving at its quickest rate, the angular velocity of the cup shall not be so great as to depress the spirits below C into the wider part of the tube. We are also, as in the figure, to have a scale of inches and tenths applied to A C, the upper and narrower part of the tube, the numeration being carried downwards from zero, which is to be placed at the point to which the column of spirits rises when the cup is at rest.

Then the instrument will be adjusted if we mark on the scale the point to which the column of spirits is depressed, when the machine is moving with the velocity required. But as in many cases, and particularly in steam-engines, there is a continued oscillation of velocity, in those cases we have to notice the two points between which the column oscillates during the most advantageous movement of the machine.

Here it is proper to observe that the height of the column of spirits will vary with the temperature, when other circumstances are the same. On this account the scale ought to be moveable, so that, by slipping it upwards or downwards, the zero may be placed at the point to which the column reaches when the cup is at rest; and thus the instrument may be adjusted to the particular temperature with the utmost facility, and with sufficient precision. The essential parts of the tachometer have now been mentioned, as well as the method of adjustment, but certain circumstances remain to be stated.

The form of the cup is adapted to render a smaller quantity of mercury sufficient than what must have been employed either with a cylindrical or hemispherical vessel. In every case two precautions are necessary to be observed:—First that, when the cup is revolving with its greatest velocity, the mercury in the middle shall not sink so low as to allow any of the spirits in the tube to escape from the lower orifice, and that the mercury, when most distant from the axis, shall not be thrown out of the cup. Secondly, that, when the cup is at rest, the mercury shall rise so high above the lower end of the tube that it may support a column of spirits of the proper length.

Now in order that the quantity of mercury, consistent with these conditions, may be reduced to its minimum, it is necessary, first, that if M M, fig. 8, is the level of the mercury at the axis when the cup is revolving with the greatest velocity, the upper part, M M X Y, of the cup should be of such a form as to have the sides covered only with a thin film of the fluid; and, secondly, that, for the purpose of raising the small quantity of mercury to the level L L, which may support a proper height of spirits when the cup is at rest, the cavity of the cup should be in a great measure occupied by the block K K, having a cylindrical perforation in the middle of it for the immersion of the tube, and leaving sufficient room within and around it for the mercury to move freely both along the sides of the tube and of the vessel.

The block K K is preserved in its proper position in the cup or vessel X Y Z, by means of three narrow projecting slips or ribs placed at equal distances round it, and is kept from rising or floating upon the mercury by two or three small iron or steel pins inserted into the under side of the cover, near the aperture through which the tube passes.

It would be extremely difficult, however, nor is it by any means important, to give to the cup the exact form which would reduce the quantity of mercury to its minimum; but we shall have a sufficient approximation, which may be executed with great precision, if the part of the cup above M M is made a parabolic conoid, the vertex of the generating parabola being at that point of the axis to which the mercury sinks at its lowest depression, and the dimensions of the parabola being determined in the following manner:—Let V, G, fig. 11, represent the axis of the cup, and V the point to which the mercury sinks at its lowest depression; at any point G above V draw G H perpendicular to V G; let n be the number of revolutions which the cup is to perform in 1″ at its quickest motion; let v be the number of inches which a body would describe uniformly in 1″, with the velocity required in falling from the rest, through a height equal to G V, and make $G H = \frac{v}{3\ 14\ n}$. Then the parabola to be determined is that which has v for its vertex, V G for its axis, and G H

for its ordinate at G. The cup has a lid to prevent the mercury from being thrown out of it, an event which would take place with a very moderate velocity of rotation, unless the sides were raised to an inconvenient height; but the lid, by obstructing the elevation at the sides of the cup, will diminish the depression in the middle, and consequently the depression of spirits in the tube: on this account a cavity is formed in the block, immediately above the level L L, where the mercury stands when the cup is at rest; and thus a receptacle is given to the fluid which would otherwise disturb the centrifugal force, and impair the sensibility of the instrument.

It will be observed, that the lower orifice of the tube is turned upwards. By this means, after the tube has been filled with spirits by suction, and its upper orifice stopped with the finger, it may easily be conveyed to the cup and immersed in the quicksilver, without any danger of the spirits escaping, a circumstance which otherwise it would be extremely difficult to prevent, since no part of the tube can be made capillary, consistently with that free passage to the fluids which is essentially necessary to the operation of the instrument.

We have next to attend to the method of putting the tachometer in motion whenever we wish to examine the velocity of the machine. The pulley F, which is continually whirling during the motion of the machine, has no connexion whatever with the cup, so long as the lever Q R is left to itself. But, when this lever is raised, the hollow cone P, which is attached to the pulley and whirls along with it, is also raised, and, embracing a solid cone on the spindle of the cup, communicates the rotation by friction. When our observation is made we have only to allow the lever to drop by its own weight, and the two cones will be disengaged and the cup remain at rest.

The lever Q R is connected by a vertical rod to another lever S, having, at the extremity S, a valve, which when the lever Q R is raised, and the tachometer is in motion, is lifted up from the top of the tube so as to admit the external air upon the depression of the spirits; on the other hand, when the lever Q R falls, and the cup is at rest, the valve at S closes the tube and prevents the spirits from being wasted by evaporation.

It is, lastly, to be remarked that both the sensibility and the range of the instrument may be infinitely increased; for, on the one hand, by enlarging the proportion between the diameters of the wide and narrow parts of the tube, we enlarge in a much higher proportion the extent of scale corresponding to any given variation of velocity; and on the other hand, by deepening the cup, so as to admit when it is at rest a greater height of mercury above the lower end of the tube, we lengthen the column of spirits which the mercury can support, and consequently enlarge the velocity which, with any given sensibility of the instrument, is requisite to depress the spirits to the bottom of the scale. Hence the tachometer is capable of being employed in very delicate philosophical experiments, more especially as a scale might be applied to it, indicating equal increments of velocity. But in the present account it is merely intended to state how it may be adapted to detect in machinery every deviation from the most advantageous movement.

MILLAR (John), LL.D., professor of civil law in the university of Glasgow, was born in the parish of Shotts, in Lanarkshire, in 1735. He was admitted a member of the faculty of advocates in 1760; and appointed professor in 1761. In 1771 he published a small work entitled Observations concerning the Ranks in Society; which passed through several editions in Britain, and acquired such celebrity on the continent, that M. Garat translated it into French. In 1787 he published An Historical View of the English Constitution; from the settlement of the Saxons in Britain to the accession of the house of Stuart. But it was chiefly as a public lecturer on law that Mr. Millar's talents were useful to his contemporaries. From his lectures on law and government, many of the first characters of the present age imbibed the rudiments of political science, and received the first impressions of attachment to freedom. He died in Glasgow, in June 1801. He was married and had several children.

MILLEDGVILLE, a town of the United States, in Baldwin county, Georgia, the seat of the state government. It is situated in the Oconee, 300 miles, by the river, from the sea, and was founded in 1806. It contains a state-house, court-house, jail, and various other public buildings. Two weekly newspapers are published here. Population 2000: 160 miles W. N.W. of Savannah.

MIL'LENARY, *adj.*
MILLENA'RIAN, *n. s.* & *adj.*
MIL'LENNIST,
MILLEN'NIUM,
MILLEN'NIAL, *adj.*
MILLES'IMAL.

Fr. *millenaire; millenarius*, Lat. Consisting of a thousand: a millenarian, or millennist, is one who expects the millennium; which is taken theologically for the reign of a thousand years, which our Saviour is expected to exercise hereafter upon earth: millennial is, pertaining to the millennium: millesimal is thousandth, consisting of thousandth parts.

Now if there be any other amongst those sixty-five places alledged by Alstedius, wherein the favourers of the *millenarian* reign can place any confidence for the evicting of their opinions, I should be glad to see it driven up to the head. *Bp. Hall.*

There is no passage in the whole book of God, wherein this *millenary* reign of saints is punctually expressed, save only this of the Revelation. *Id.*

For, besides that the *millenary* opinion is expressly taught by Papias, Justyn Martyr, and divers others famous in their time: Justin Martyr in his dialogue against Tryphon says it was the belief of all Christians exactly orthodox. *Jer. Taylor.*

We must give a full account of that state called the *millennium*. *Burnet's Theory of the Earth.*

To be kings and priests unto God, is the charac-

teristic of those that are to enjoy the *milennial* happiness. *Burnet.*

The *millennary* sestertium, in good manuscripts, is marked with a line across the top thus HS.

Arbuthnot on Coins.

To give the square root of the number two, he labored long in *millesimal* fractions, till he confessed there was no end. *Watts.*

MILLENNIUM. A thousand years; generally signifying the 1000 years during which, according to an ancient tradition in the church, grounded on a text in the Apocalypse, our Saviour is to reign with the faithful upon earth after the resurrection, before the final completion of beatitude.

MILLENNIUM is derived from mille anni, 1000 years. Though there has been no age of the church in which the millennium was not admitted by individual divines of the first eminence, yet it is evident from the writings of Eusebius, Irenæus, Origen, and others, among the ancients, as well as from the histories of Dupin, Mosheim, and all the moderns, that it was never adopted by the whole church, or made an article of the established creed in any nation. About the middle of the fourth century, the Millenarians held the following tenets: 1st, That the city of Jerusalem shall be rebuilt, and that the land of Judea shall be the habitation of those who are to reign on earth 1000 years. 2dly, That the first resurrection is not to be confined to the martyrs; but that after the fall of antichrist all the just are to rise, and all that are then on the earth are to continue for that space of time. 3rdly, That Christ shall then come down from heaven, and be seen on earth, and reign there with his servants. 4thly, That the saints, during this period, shall enjoy all the delights of a terrestrial paradise. These opinions were founded upon several passages of Scripture, which the millenarians among the fathers understood in a literal sense, but which the moderns, who hold that opinion, consider as partly literal and partly metaphorical. Of these passages, that upon which the greatest stress has been laid is in Rev. xx. 1—6. Most modern critics contend that the prophecies of the millennium point, not to a resurrection of martyrs and other just men to reign with Christ 1000 years in a visible kingdom upon earth, but to that state of the Christian church which, for 1000 years before the general judgment, will be so pure and so widely extended, that, when compared with the state of the world in the ages preceding, it may be called a resurrection from the dead.

Such is a brief and fair historical view of this question. In modern times the extended circulation of the Scriptures has brought this, in common with every other topic of God's word, into more frequent consideration: able men have espoused the opinions of the old millenarians; while some have advocated a theory that seems to involve two millennia; and others (the most modern expounders of the subject), connect the millennium with the immediate return of the Jews to Palestine, and an exclusive exaltation of that people, under the personal reign of the Messiah, over all the nations of the earth. The most common modern opinion confines all the predictions respecting what has been called the millennium to a spiritual reign of Christ by means of the universal reception of the gospel, and has been thus stated:—1. That the Scriptures afford us ground to believe that the church will arrive to a state of prosperity which it never has yet enjoyed, Rev. xx. 4, 7.; Psal. lxxii. 11; Isa. ii. 2, 4; xi. 9; xlix. 23; lx.; Dan. vii. 27 2. That this will continue at least 1000 years, or a considerable space of time, in which the work of salvation may be fully accomplished in the utmost extent and glory of it. In this time, in which the world will be filled with real Christians, and continue full by constant propagation to supply the place of those who leave the world, there will be many thousands born and live on the earth, to each one that has been born and lived in the preceding 6000 years; so that, if they who shall be born in that 1000 years shall be all, or most of them, saved (as they will be), there will, on the whole, be many thousands of mankind saved to one that shall be lost. 3. This will be a state of great happiness and glory. While some think that Christ will reign personally on earth, and that there will be a literal resurrection of the saints, Rev. xx. 4, 7, these writers suppose that the reign of Christ and resurrection of saints alluded to in that passage, are only figurative; and that nothing more is meant than that, before the general judgment, the Jews shall be converted, genuine Christianity be diffused through all nations, and that Christ shall reign, by his spiritual presence, in a glorious manner. It will, however, be a time of eminent holiness, clear light and knowledge, love, peace, and friendship, agreement in doctrine and worship. Human life, perhaps, will rarely be endangered by the poisons of the mineral, vegetable, and animal kingdoms. Beasts of prey, perhaps, will be extirpated, or tamed by the power of man. The inhabitants of every place will rest secure from fear of robbery and murder. War shall be entirely ended. Capital crimes and punishments be heard of no more. Governments placed on fair, just, and humane foundations. The torch of civil discord will be extinguished. Perhaps Pagans, Turks, Deists, and Jews will be as few in number as Christians are now. Kings, nobles, magistrates, and rulers in churches shall act with principle, and be forward to promote the best interests of men: tyranny, oppression, persecution, bigotry, and cruelty, shall cease. Business will be attended to without contention, dishonesty, and covetousness. Merchandise between distant countries will be conducted without fear of an enemy. Learning, which has always flourished in proportion as religion has spread, shall then greatly increase, and be employed for the best of purposes. Above all, the Bible will be more highly appreciated, its harmony perceived, its superiority owned, and its energy felt by millions of human beings. In fact, 'the earth shall be filled with the knowledge of the Lord as the waters cover the sea.' 4. The time when this millennium will commence cannot be fully ascertained; but the common idea is, that it will be in the 7000th year of the world. It will, most probably come on by degrees, and be in a manner intro-

duced years before that time. The overthrow which popery has had in places where it has been so dominant for hundreds of years seems to prepare for it; the fulfilment of prophecy respecting infidels, and the falling away of many in the last times; and yet, in the midst of all, the number of missionaries sent into different parts of the world, together with the increase of gospel ministers; the thousands of ignorant children that have been taught to read the Bible, and the vast number of different societies that have been instituted for the benevolent purpose of informing the minds and impressing the hearts of the ignorant.— See *Hopkins on the Millennium; Whitby's Treatise on it, at the end of the second volume of his Annotations on the New Testament; Bishop Newton's Twenty-fifth Dissertation on the Prophecies; Bellamy's Treatise on the Millennium, &c.*

Dr. Gill is an advocate for both a spiritual and a personal future reign of Christ on earth. Considering the antichrist of John and the 'man of sin' of St. Paul, as identical, he observes that, of the latter, it is said he shall be consumed by the spirit of' Christ's 'mouth,' which is the preaching of the gospel: this, he conceives will bring on the period of the 'fulness of the gentiles' when the Jews shall be converted (popery having been destroyed): that they shall then join themselves every where, and, as it were, simultaneously to Christian churches: when 'they will return to their own land and possess it, being assisted by the Protestant princes, who will drive out the Turk.' Afterwards he expects the large conversions to God mentioned Isa. lx.; and that the interest and church of Christ will 'make the greatest figure it ever did in the world.'

To this, nearly similar with the foregoing view of Christ's spiritual reign, he adds, as his opinion, that 'Christ will have a special, peculiar, glorious, and visible, kingdom' on earth immediately succeeding his second coming, and the resurrection of all deceased believers: he understands, therefore, literally the former part of Rev. xx. and St. Paul in 1 Thess. iv.

But the most remarkable of modern opinions on this subject, and one worth recording, perhaps, that events may testify to its truth or error, is that so warmly espoused of late by several evangelical clergymen of the church of England and the Rev. Mr. Irving. The latter has, at least, made himself intelligible on this subject; and protests that he is greatly afflicted because of the present unawakened and even dead condition of all the churches with respect to the coming of our Lord Jesus Christ, which is, as he believes, 'close at hand.' He thus delivers his judgment on the subject.

1. 'That the present visible church of the Gentiles, which hath been the depository of the oracles and the sacraments, and the ordinances, since the Jewish state was dissolved, I mean the mixed multitude who are baptised in the name of the Father, and the Son, and the Holy Ghost, under that seal including Protestants, Roman Catholics, Greek church, Armenians, &c., and all the sects of each, as Scottish, English, Irish, Lutheran and Calvinistic churches, with the dissenters and seceders from each, that this body of baptised men, which I call the Gentile church, who should every one of them have been a saint; being 'by baptism ingrafted into Christ Jesus to be made partakers of his justice, whereby our sins are covered and remitted;' standeth threatened in the Holy Scriptures because of its hypocrisies, idolatries, superstitions, infidelity, and enormous wickedness, 'because it hath transgressed the laws, changed the ordinance, and broken the everlasting covenant' (Isaiah xxiv.), with such a terrible judgment, as hath not been, nor ever shall again be seen upon the earth; in the which deluge of wrath she shall be *clean dissolved*, as the synagogue was heretofore in the destruction of Jerusalem, when she in like manner had filled up the measure of her iniquity:— which fearful consummation I judge to be close at hand, both by the signs of the times, and from the prophetic numbers expressly given to guide us in the anticipation of these great Gentile judgments, which are mentioned in Scripture wherever and whenever the coming of the Lord is mentioned.

2. 'When the Lord shall have finished the taking of witness against the Gentiles, and summed up the present dispensation of testimony in this great verdict of judgment, and while the execution is proceeding, he will begin to prepare another ark of testimony, or rather to make the whole earth an ark of testimony; and to that end will turn his Holy Spirit unto his ancient people the Jews, and bring unto them those days of refreshing spoken of by all the holy prophets since the world began: in the which work of conveying to them his Spirit, by the preaching of the word, he may, and it is likely will, use the election according to grace, who still are faithful amongst the Gentiles; though I believe it will chiefly be by the sending of Elias, who is promised before the dreadful and terrible day of the Lord, and by other mighty and *miraculous* signs. This outpouring of the Spirit is known in Scripture by 'the latter rain,' of which I deem the religious revivals of the last thirty years to be as the first droppings of the shower, and our religious works and societies to be a sickly uncertain hue of verdure, which the withered stump by the scent of the waters hath put forth, and like all God's gifts it will be given to those who will receive it, both Gentiles and Jews, and will prove the touchstone of both;—amongst the Gentile church awakening those persecutions of the last Antichrist which the faithful are taught to expect immediately before the coming of the Lord, and of which they have already had a foretaste in several of the Protestant churches abroad; in the Jewish church accomplishing that refining and passing through the fire which is spoken of immediately on their restoration. (Mal. iii. 3; Zech. xiii. 9). Which Antichristian spirit among the Gentiles, and enraged infidel spirit among the Jews, may amalgamate with one another, to produce a spurious restoration of the nations to their own land, and occasion that great warfare in the neighbourhood of Jerusalem, when Antichrist shall fall, and his powers be broken, in the battle of Armageddon. But the faithful among the Jews, now brought to believe on him whom

they have pierced, shall in the mean time be prepared by much sorrow, and distress, and supplication, for the coming of the Lord to settle and establish them surely and for ever in their own land; and the faithful among the Gentiles shall be expecting the Lord to deliver them, according to the promises which he hath made to his elect church of being raised from the dead, or changed among the living at his coming, and all gathered to him in that day. It was my second proposition, that in this way the Lord will be preparing for himself an ark of testimony in the Jewish nation, through whom to make the whole world one great and universal ark of faithful testimony.

3. 'That these judgments upon the Gentile nations, and all the earth, he will finish by his own personal appearance in flaming fire, taking vengeance on those who know not God and obey not the gospel of our Lord Jesus Christ; raising those who sleep in Jesus, and changing those of the Gentile church who still abide in life; and preserving the mourning Jewish church, as Goshen was preserved in the plagues of Egypt: and when the promised land shall have been cleared of all intruders, and they themselves by suffering perfected for the habitation of it, he shall lead them into it with a mighty and outstretched arm: and sit upon the throne of David, judging and seeking judgment, and hasting righteousness; and send forth the law from Zion, and the word of the Lord from Jerusalem; and rule among the nations, and be the prince of universal peace; using in this judgment and government of the earth his risen saints, who shall be his ministers to execute whatever his pleasure is. And thus, Satan being cast out, and the prince of light, and the heavenly Jerusalem, the dwelling place of his elect church being present, the Jerusalem on earth, with the house of Jacob, and all the nations, shall enjoy that fulness of peace and joy, that millennial reign of righteousness, for which we all hope and pray, and diligently labor.'

He afterwards thus meets what he considers as the two principal objections to his theory:—

'But here two questions present themselves. 1. If, as you have argued, the world be of such rebellious stuff, that in the face of this dispensation of witness and testimony, sustained all the while by an active Providence, it will not amend its obstinate ways, but persevere in them to the end; yea, and wax bolder and bolder against God and his chosen ones; until it is necessary to take measures that the cause of righteousness perish not utterly, by coming upon the confident world with a series of judgments, which shall make it reel to and fro like a drunkard, and consume its inhabitants, till hardly 'a gleaning as of the vintage grapes is left;' how all at once shall it come to pass that the most obstinate of the nations shall at once be converted, and the whole world follow in its train, and persevere in a state of peace and blessedness? This is precisely the question to which I desire the attention of the church. How, indeed, will that great revolution be effected? I have a means most effectual in the casting out of Satan with all his angels from the possession of the earth and the heavens, in the destruction of all his works of despotism and superstition, infidelity and radicalism from the face of the whole earth. He who was the beginner of the declension, and of all the mischief which the earth has endured, must be cast out by the seed of the woman, before the warfare will end which the seed of the woman in his church hath maintained till this hour against the serpent and his generation of vipers. This is the great work behind the scenes in the spiritual world, out of the observation of the sense of man, which will prepare the way for the great work of peace and blessedness, which will then follow, almost as of course, before the scenes, that is in the intercourse and conduct of men. I say almost of course, yet not altogether of course; because though Satan shall then be cast out of the world, and his active temptations wholly at an end, men will still be in the flesh and heirs of death, during the whole period of the millennial kingdom. And therefore they will need government, both civil and ecclesiastical, a law and a religion, or rather a law in a religion; that is, the same law of righteousness which we now possess, administered according to the wisdom of Christ and his reigning church, without any opposition or strife of Satan. Power shall then be holy; and the creation shall then be pure, and the bondage of Satan shall have ceased. There is not only this negative, but also another provision of a positive kind, which answers to the second question that might be started from the premises, viz. And what is to become of those spiritual witnesses, who since the calling of Abraham have been raised up in the likeness of Christ Jesus, to preserve the testimony of the righteousness which is by faith in his blood? What is to become of this elect church that have suffered, before his incarnation and since his incarnation, by the same eternal Spirit, and for the same end of the Father's glory for which he suffered? To this I answer that the whole Scripture, from the beginning to the ending of it, doth testify that they shall come with Christ to be partakers of his glory, that he may be glorified in them in whom also he was dishonored; and that they may be the sharers of that throne, and kingdom, and power, whereof he hath the promise from the Father, and is now expecting the fulfilment. These are the dead who shall hear the voice of the Son of God and live. These are they who shall be changed. These are they who shall meet the Lord in the air, and reign with him on the earth, and be for ever with the Lord, in that new Jerusalem which cometh down from heaven. This new Jerusalem is that which flesh and blood cannot inherit, where they neither marry nor are given in marriage, but are like the angels of God. And this is that of which the pillar of fire was the emblem in the wandering church; and the Shechinah, or glory between the cherubim, was the emblem in the resting church. There shall be to the whole earth such a glory, beyond the light of the sun, as there was in the holy of holies in the temple of Jerusalem; in which shall dwell the shining ones, the companions of the Lord, the true priesthood after the order of Melchisedek, who shall undertake the

government of the whole earth, and carry it on under the great king; by whose active ministry, by whose speedy obedience, passing to and fro at will with angelic freedom and readiness, they shall preserve and maintain that peace and blessedness amongst the sojourners of the earth, in which the millennium will consist. And thus, without going into further particulars, it is that the change in the world's temper and condition will be accomplished; and thus that the elect church will be rewarded by being made the spouse, the sister of the king, the joint-heirs, the fellow-judges, and governors, and possessors of the kingdom.

'Such, in few words, is the form of doctrine concerning the second advent of our blessed Lord, which was made known to me in the much study of the Holy Scriptures; and which, after several months of secret meditation, I began last Christmas, with all discretion and with fear and trembling, to break up and deal out to the church which God hath committed to my charge, resting and grounding the substance of it all upon the very words of our Lord himself, and using the Old Testament only when the language manifestly carried me thither, and the other books of the New Testament for further exposition and unfolding of those seeds of truth which are all contained in our Lord's own recorded discourses. For I hold it to be a great principle, which may almost be laid down as a canon of exposition, that every fundamental truth of faith should be shown to be present under some form or other, in every part, or rather I should say in every period, of divine revelation, unfolding itself more and more onwards to the end.'

We cannot afford space for a more enlarged view of this new scheme. The above are extracts from the Preliminary Discourse of this popular commentator, prefixed to his Translation of a Spanish work entitled La Venida del Mesias en Gloria y Majestad, 1827.

MILLE PASSUS, or MILLIA PASSUUM, a very common expression among the ancient Romans for a measure of distance, commonly called a mile. Milliarium was rarely used. Heyschius made it to consist of seven stadia; Plutarch little short of eight; but Strabo, Polybius, and many others, make it just eight stadia. This distance is sometimes called lapis. Each passus consisted of five feet.

MILLEP'EDES, *n. s.* Fr. *mille-pieds;* Lat. *mille* and *pes*, foot. A species of wood-lice, well furnished with feet, as well as teeth.

If pheasants and partridges are sick, give them *millepedes* and earwigs, which will cure them.

Mortimer's Husbandry.

MILLEPES, or wood-louse, in entomology, a species of oniscus. These insects are found in cellars, under stones, and in cold moist places; in the warmer countries they are rarely met with. Millepedes have a faint disagreeable smell, and a somewhat pungent, sweetish, nauseous taste.

MILLEPORA, in natural history, a genus of lithophytes, of a hard structure and full of holes, which are not stellate or radiated, and whose animal is the hydra. It differs from the madrepora, and comprehends fourteen different species. The animal, which forms and inhabits the millepora, occupies the substance; and the milleporæ grow upon one another; these little animals produce their spawn, which, attaching itself either to the extremity of the body already formed, or underneath it, gives a different form to this production. Hence the various shapes of the millepora, which is composed of an infinite number of the cells of those little insects, which all together exhibit different figures, though every particular cellula has its essential form, and the same dimensions, according to its own species.

MILLER (Joseph), a witty actor, whose name is identified with a low kind of wit where-ever the English language is known, was born in London in 1684, and was a favorite low comedian. He performed Sir Joseph Wittol, in Congreve's Old Bachelor; and Ben in Love for Love. Another of his characters was Teague, in The Committee. He died August 15th, 1738, and was buried in the church-yard of St. Clements, where a stone (recently renewed) was placed to his memory, with an epitaph, written by 'Stephen Duck.' The jests which have immortalised his name were collected by John Mottley, author of the Life of Peter the Great, and other works. They had run through eleven editions in 1751, and were reprinted, after a lapse of thirty years, by Barker, of Russel Street. A copy of the original edition was lately valued at ten guineas.

MILLER (James), an English dramatic writer, born in Dorsetshire, in 1703. He studied at Oxford, entered into orders, and published, 1. The Humors of Oxford, a comedy; acted in 1729: 2. Mahomet, a tragedy; which had a great run: 3. A volume of Sermons: 4. Poems, &c. He died in 1743.

MILLER (Philip), F.R.S., a celebrated botanist and gardener, born in Scotland, in 1691. He succeeded his father as gardener to the Apothecaries' Company at Chelsea, in 1722. He published several works, the principal of which is his Gardener's Dictionary, in folio. He died in 1771.

MILLER (Edward), music doctor, was of humble parentage and born at Norwich in 1736. Eloping from his father, he went to Lynn, where Dr. Burney first discovered his genius for music. He obtained in 1756 the appointment of organist at Doncaster, and after continuing in this situation thirty years took his doctor's degree at Cambridge. To his skill on the organ, he added that of an excellent flute player, and performed upon this instrument in Handel's oratorios. Dr. Miller was the author of The elements of Thorough Bass and Composition; The Institutes of Music; and of a topographical work of merit on the History and Antiquities of Doncaster. He also arranged and published a set of new melodies for the Psalms. His death took place at Cambridge in 1807.

MILLERIA, a genus of the polygamia necessaria order, and syngenesia class of plants; natural order, forty-ninth, compositæ.

MILLES (Jeremiah), F.R.S., a learned antiquary and divine, born in Hampshire, in 1713, and educated at Eton and Baliol Colleges, Oxford; of which his father, Jeremiah, was tutor and

fellow. He took his degree of A. M. in 1735, and of D.D. in 1747. His uncle, Thomas Milles, bishop of Waterford, gave him a prebend, and left him a large fortune in 1740. He married a daughter of archbishop Potter, through whom he obtained various preferments in England, the last of which was the deanery of Exeter, in 1762. In 1759 he was elected president of the Antiquarian Society. He published an elegant edition of Rowley's Poems, with a glossary; but was treated with great asperity by his opponents in that controversy. He also published a sermon, several papers in the Archeologia, and left many curious MSS. on Doomsday Book, on the Danish coinage, and ample materials for a history of Devonshire. He died at London, February 13th, 1784, aged seventy-one, leaving three sons and two daughters.

MILLESIMO, a town of France, in the department of the Stura, and late duchy of Montserrat, ten miles east of Ceva. On the 11th of April, 1796, the defiles leading to it were forced by the French under Buonaparte and Augereau, and the Austrians under general Provera, defeated with the loss of 1500 grenadiers; and on the 16th a second battle took place, in which the Austrians were again defeated, about 1000 men killed, and general Provera obliged to surrender with 9000 men, thirty-two pieces of cannon, and fifteen pairs of colors.

MIL'LET, *n. s.* Fr. *millet;* Ital. *milgio;* Lat. *milium.* A plant, see MILIUM. Also misprinted for MULLET, a fish, which see.

Some fish are gutted, split, and kept in pickle; as whiting, mackerel, *millet.* *Carew.*

In two ranks of cavities is placed a roundish stud, about the bigness of a grain of *millet.*
Woodward on Fossils.

Millet is diarrhœtick, cleansing, and useful in diseases of the kidneys. *Arbuthnot on Aliments.*

The *millet* hath a loose divided panicle, and each single flower hath a calyx, consisting of two leaves, which are instead of petals, to protect the stamina and pistillum of the flower which afterwards becomes an oval shining seed. This plant was originally brought from the eastern countries, where it is still greatly cultivated, from whence we are annually furnished with this grain, which is by many persons much esteemed for puddings. *Miller.*

MILLET, in botany. See MILIUM.

MILLET GRASS. See PANICUM.

MILLET, INDIAN. See HOLCUS.

MILLETIERE (Theophilus Brachet), lord of, a Protestant French advocate of the seventeenth century, who studied the law at Heidelberg; afterwards studied Hebrew, became a divine, and obtained an office in the consistory of the church of Paris. Being elected a representative of the assembly of Rochelle, he had a principal hand in their most spirited resolutions, and wrote a work encouraging the reformers to take up arms; upon which he was imprisoned and put to the torture. Yet, after all this, being liberated, he turned Roman Catholic, in 1645, and wrote several tracts for the purpose of reconciling the Huguenots to the mother-church, which only procured him the ill will of both parties. He died in 1665.

MILLIARIUM AUREUM was a gilded pillar in the forum of Rome, at which all the highways of Italy met, as one common centre. From this pillar the miles were counted, and at the end o every mile a stone was put down. The miliary column was erected by Augustus Cæsar, and is still to be seen.

MI'LLINER, *n. s.* I believe from Milaner, an inhabitant of Milan, as a Lombard is a banker.—Johnson. But there is a Goth. and Swed. *milla* and *molla,* to divide, and also to deal. One who sells ribands and dresses for women.

He was perfumed like a *milliner;*
And 'twixt his finger and his thumb he held
A pouncet box, which ever and anon
He gave his nose. *Shakspeare. Henry IV.*

The mercers and *milliners* complain of her want of publick spirit. *Tatler.*

If any one asks Flavia to do something in charity, she will toss him half a crown, or a crown, and tell him, if he knew what a long *milliner's* bill she had just received, he would think it a great deal for her to give. *Law.*

MILLION, *n. s.* } Fr. *million;* Ital. *milliogne.*
MILLIONTH, *adj.* } Ten hundred thousand; taken proverbially for any very large number.

Within thine eyes sat twenty thousand deaths,
In thy hands clutched as many *millions,*
In thy lying tongue both numbers. *Shakspeare.*

There are *millions* of truths that a man is not concerned to know. *Locke.*

She found the polished glass whose small convex
Enlarges to ten *millions* of degrees
The mite, invisible else. *Phillips.*

Midst thy own flock, great shepherd, be received;
And glad all heaven with *millions* thou hast saved.
Prior.

The first embrio of an ant is supposed to be as big as that of an elephant; which nevertheless can never arrive at the *millionth* part of the other's bulk. *Bentley.*

The *million* flit as gay
As if created only like the fly,
That spreads its motley wings in the eye of noon,
To sport their season, and be seen no more.
Cowper.

MILLO, a part of mount Zion at its extremity; and therefore called Millo of the city of David (2 Chron. xxxii.), taken in with the wall that encompassed mount Zion. It is uncertain whether Beth-Millo (Judges ix. 20) denotes a place; if it did, it lay near Shechem.

MILLOT (Claude Francis Xavier), a member of the French academy, born at Besançon, in March 1726, and for some time a Jesuit. He continued to preach after he left the Society: but the weakness of his voice and his timidity, not permitting him to continue in this profession, he relinquished it. The marquis of Felino, minister of Parma, having instituted an historical class for the benefit of the young nobility, he gave the charge of it to abbé Millot. After having filled the historical chair, with great approbation, he returned to France, and was appointed preceptor to the duke of Enghien. In this situation he died, A. D. 1785, aged fifty-nine. He composed several works, which are digested with great care, and written in a pure, simple, and natural style. The principal are, 1. Elemens de l'Histoire de France, depuis Clovis jusque à Louis XIV. 3 vols. 12mo, 2. Elemens de l'Histoire d'Angleterre, depuis son origine sous les

Romains, jusqu' à George II.; 3 vols. 12mo. 3. Elemens de l'Histoire Universelle, 9 vols. 12mo. 4. L'Histoire des Troubadours, 3 vols. 12mo, compiled from the MSS. of M. de Sainte-Palaie. 5. Memoires Politiques et Militaires, pour servir à l'Histoire de Louis XIV, et de Louis XV., composed from original papers collected by Adrian Maurice, duke of Noailles, marshal of France, in 6 vols. 12mo. 6. Several Discourses on Philosophical Questions; and 7. Translations of the most Select Harangues in the Latin Historians.

MILMAN (Sir Francis), M. D., baronet, was the son of a clergyman of Devonshire, where he was born in 1746. After receiving a grammatical education with a view to the church he entered of Exeter College, Oxford, where, in 1767, he took the degree of M. A., but directed his attention to physic: in 1770 he proceeded to the degree of bachelor in that faculty. In 1776 he completed his graduation as a doctor, and now entered into orders, actually taking his degree of B. D. in 1778. Returning to the practice of physic, he travelled on Dr. Radcliff's foundation, and attended the duke of Gloucester at Rome. This circumstance fixed his professional pursuits; on his return to England, he became a member of the Royal Society, and a fellow of the College of Physicians, by whom, in 1780, he was appointed to deliver the Gulstonian lecture. After this he was nominated physician to the king and the royal household; which procured his elevation to the baronetage. He died June 24th 1821. Sir Francis was the author of Animadversiones de Natura Hydropis ejusque curatione, 8vo. 1779; and A Treatise on the Source of the Scurvy and Putrid Fever, 8vo. 1782.

MILNE (Colin), LL. D., a divine and botanist, was born at Aberdeen, and educated at the Marischal College there, under his uncle, Dr. Campbell. Thence he removed to Edinburgh; after which, becoming tutor to lord Algernon Percy, he took orders in the church of England, and was presented to the rectory of North Chapel, Essex. He was also chosen lecturer of Deptford, and obtained the degree of doctor of laws from Aberdeen. He died in 1815. He published 1. A Botanical Dictionary, 8vo. 2. Linnæi Institutiones Botannicæ, 4to. 3. Indigenous Botany, or the Habitats of English Plants. 4. A volume of sermons, 8vo.

MILNER (Joseph), a modern divine, and ecclesiastical historian, was the son of a poor weaver at Leeds, and born there in 1744. He was educated at the free grammar-school, and at Catherine Hall, Cambridge, where he took his bachelor's degree in 1766, and obtained one of the chancellor's medals. Entering into orders he became master of the grammar-school, and afternoon lecturer, at Hull. He was afterwards presented to the vicarage of North Ferriby; and latterly to that of the Holy Trinity church in Hull. He died November 15th, 1797. His works are, 1. The Life of William Howard. 2. Answer to Gibbon's Attack on Christianity. 3. Essays on the Influence of the Holy Spirit. 4. A History of the Church of Christ, 4 vols. 8vo. 5. Two volumes of sermons, with his life prefixed.

MILNER (Isaac), D. D., younger brother of the preceding, was actually brought up to the weaving business; but, while at the loom, was so intent on study, and so devoted to the classics and mathematics, that his brother took him for an assistant in the grammar-school, and afterwards sent him to Queen's College, Cambridge, where, in 1774, he was senior wrangler, and gained the first mathematical prize. He soon became a tutor in that science; and, among other pupils, had Mr. Wilberforce and Mr. Pitt, with whom he made a tour on the continent. In 1783 he was appointed professor of natural philosophy; and in 1788 elected master of his college. The same year he was made dean of Carlisle; in 1792 he served the office of vice-chancellor; and in 1798 succeeded Waring as Lucasian professor of mathematics. He died in 1820. His publications are, 1. Animadversions on Hawker's Church History. 2. A Continuation of his brother's Ecclesiastical History. 3. Strictures on the Publications of Dr. Marsh, respecting the Bible Society. 4. Life of Mr. Joseph Milner, prefixed to his sermons.

MILO, the son of Diotimus, a celebrated athlete of Crotona in Italy. He early accustomed himself to carry the greatest burdens, and by degrees became a prodigy of strength. It is said that he carried on his shoulders a young bullock, four years old, for above forty yards; afterwards killed it with one blow of his fist, and ate it up in one day. He was seven times crowned at the Pythian games and six at the Olympian. He presented himself a seventh time; but no one had the courage or boldness to enter the lists against him. He was a disciple of Pythagoras; and to his uncommon strength, it is said, the learned preceptor and his pupils owed their lives. The pillar which supported the roof of the school suddenly gave way, but Milo supported the whole weight of the building, and gave the philosopher and his auditors time to escape. In his old age, Milo attempted to split a growing tree, and partly effected it; but his strength being gradually exhausted, the tree, when half cleft, reunited, and his hands remained pinched in the body of the tree. He was then alone; and, being unable to disentangle himself, he was devoured by wild beasts, about A. A. C. 500.

MILO (T. Annius), a native of Lanuvium, who attempted to obtain the consulship at Rome. Clodius the tribune opposed his views, yet Milo would have succeeded had not an unfortunate circumstance taken place between his suite and that of Clodius as he was going to the country. Clodius and eleven of his servants were killed, and the body of the murdered tribune was carried to Rome and exposed to public view. Cicero, as is well known to every classical student, undertook the defence of Milo, but with no effect; he was condemned and banished to Massalia.

MILO, an island in the Archipelago, anciently called Melos, about sixty miles in circumference, with a harbour, which is one of the largest in the Mediterranean. This island was formerly rich and populous. From the earliest times of antiquity it enjoyed liberty; but, the Melians having refused to join the Athenians in the Peloponnesian war, the latter made a descent upon the

island, and, although in two different expeditions they failed of their purpose, they accomplished it in the third, and killed or carried captive all the inhabitants. See MELOS. This act of cruelty disgraces the Athenian name. But Lysander, the Lacedemonian general, expelled the Athenian colony and re-established the remains of its original inhabitants. Melos afterwards lost its liberty when the Romans conquered all the isles of the Archipelago. In the partition of the empire, it fell to the eastern emperors, was governed by dukes, and was at last conquered by Soliman II. Since that period it has groaned under the yoke of Turkish despotism, and has lost its opulence and splendor. At the commencement of the eighteenth century it had seventeen churches, eleven chapels, and above 20,000 inhabitants. It was very fertile in corn, wine, and fruits; and the whole space from the town to the harbour, which is nearly two miles, was laid out in beautiful gardens. M. Tournefort, who visited it in 1700, gives the following fine description of it. 'The earth, being constantly warmed by subterraneous fires, produced almost without interruption plentiful crops of corn, barley, cotton, vines, and melons. St. Elias, the finest monastery in the island, and on the most elevated spot, is encircled with orange, citron, cedar, and fig trees. Its gardens are watered by a copious spring. Olive trees grow in great abundance around it. The vineyards afford excellent wine. In a word, all the productions of the island are the very best of their kinds; its partridges, quails, kids, and lambs, are highly valued, and yet may be bought at a very cheap price.' But M. Savary says, in his forty-second Letter on Greece, that 'were M. Tournefort to return to Milo, he would no longer see the fine island which he has described. He might still see alum, in the form of feathers, and fringed with silver thread, hanging from the arches of the caverns; pieces of pure sulphur filling the cliffs of the rocks; a variety of mineral springs; hot baths, though these are now only a set of small dirty caves; the same subterraneous fires which in his days warmed the bosom of the earth, and were the cause of its extraordinary fertility: but instead of 5000 Greeks, paying the capitation tax, he would now find no more than about 700 inhabitants on an island eighteen leagues in circumference. He would sigh to behold the finest lands lying uncultivated, and the most fertile valleys converted into morasses; of the gardens scarcely a vestige left; three-fourths of the town in ruins, and the inhabitants daily decreasing. During the last fifty years, Milo has assumed a quite different appearance. The plague, which the Turks propagate every where, has cut off one part of its inhabitants; the injudicious administration of the Porte, and the oppressive extortions of the pacha, have destroyed the rest. For want of hands, they cannot cut out a free channel for their waters, which stagnate in the valleys, corrupt, and infect the air with their putrid exhalations. The salt marshes, being equally neglected, produce the same effects. Sulphureous exhalations arise all over the island, by which the inhabitants of Milo are afflicted with dangerous fevers during three-fourths of the year. Yet a judicious and enlightened government might expel those evils. The whole inhabitants of this island are now below 1000, of whom not the fifth part inhabit the petty village which is the chief place. Long. of the harbour of Milo, 24° 13′ 32″ E., lat. 36° 42′ 30″ N.

MILT, *n. s.* & *v. a.* } Saxon milt; Belgic
MIL'TER, } *mildt*; Teut. *miltz*; Ital. *millte*. The spleen; the sperm of a male fish: to milt is to impregnate the roe or spawn of the female fish: milter is a name for the male.

You shall scarce take a carp without a *melt*, or a female without a roe or spawn. *Walton's Angler.*

The spawner and *milter* labor to cover their spawn with sand. *Id.*

MILT, or MELT, in natural history, the soft roe in fishes, thus called from its yielding, by expression, a whitish juice resembling milk.

MILTHORP, a town of Westmoreland, at the mouth of the Can, five miles from Kendal. It is the only sea-port in the county, and goods are brought hither in small vessels from Grange in Lancashire. Here are two paper-mills. It has a market on Friday, with a fair on old May-day; and a good stone bridge over the river Betha, which runs through the town.

MILTIADES, an Athenian general, son of Cypselus. He obtained a victory in a chariot-race at the Olympic games. He led a colony of Athenians to the Chersonesus. The causes of this appointment are striking and singular. The Thracian Dolonci, harassed by a long war with the Absynthians, were directed by the oracle of Delphi to take for their king the first man they should meet in their return home, who should invite them to come under his roof, and partake his entertainments. They met Miltiades, whom their appearance, with their strange arms and garments, struck. He invited them to his house, and was made acquainted with the commands of the oracle. He obeyed; and, when the oracle of Delphi had approved a second time the choice of the Dolonci, he departed for the Chersonesus, and was invested by the inhabitants with sovereign power. The first measure he took was to stop the further incursions of the Absynthians by building a strong wall across the Isthmus. When he had established himself, and fortified his dominions, he turned his arms against Lampsacus. He was afterwards taken in an ambuscade, but Crœsus, king of Lydia, procured his release. He lived a few years after he had recovered his liberty. As he had no issue he left his kingdom and possessions to Stesagoras, the son of Cimon, who was his brother by the same mother. The memory of Miltiades was greatly honored by the Dolonci; and they regularly celebrated festivals in commemoration of a man to whom they owed their preservation and greatness.

MILTIADES, the son of Cimon, and brother of Stesagoras above mentioned, was, some time after the death of the latter, who died without issue, sent by the Athenians, with one ship, to take possession of the Chersonesus. At his arrival Miltiades appeared mournful, as if lamenting the recent death of his brother. The principal inhabitants of the country visited the new governor to condole with him; but Miltiades abused their con-

fidence, seized their persons, and made himself absolute in Chersonesus. To strengthen himself he married Hegesipyla, the daughter of Olorus, king of the Thracians. When Darius I., king of Persia, undertook an expedition against the Scythians, and throwing a bridge across the Danube marched into their country, he entrusted the guard of the bridge to the Ionian Greeks, the commanders of whom he had attached to himself by raising them to the supreme authority in their several cities. Miltiades, who was one of them, excited by that spirit of Grecian patriotism to which every other duty was made subservient, urged the other leaders to break down the bridge, in order that a prince so entirely inimical to Grecian liberty might never return in safety. His council was approved by all the rest except Hystiæus the Milesian, who had influence enough to prevent its taking effect. Miltiades, judging it imprudent to await the monarch's return, embarked for Athens, and in his way took possession of the isle of Lemnos for his countrymen. At the celebrated battle of Marathon all the chief officers ceded their power to him; and, by his superior abilities, an important victory was gained over the more numerous forces of the Persians. Some time after Miltiades was entrusted with a fleet of seventy ships, and ordered to punish those islands which had revolted to the Persians. He was successful at first; but, on a sudden report that the Persian fleet was coming to attack him, as he was besieging Paros, he raised the siege, and returned to Athens. He was accused of treason, and Miltiades, not being able to come into the assembly on account of a wound which he had received before Paros, his enemies, taking advantage of his absence, became more eager in their accusations. He was condemned to death, but the rigor of his sentence was retracted on account of his great services to the republic; and he was put in prison till he should pay a fine of fifty talents to the state. His inability to discharge so great a sum detained him in confinement; and, his wounds becoming incurable, he died a prisoner about A. A. C. 489. His body was ransomed by his son Cimon, who was obliged to borrow fifty talents to give his father a decent burial. The accusations against him were the more readily believed, because he had made himself absolute in Chersonesus. Cornelius Nepos has written the life of Miltiades; but he confounds the actions of the son of Cimon with those of the son of Cypselus.

MILTON (John), the most illustrious of the English poets, was descended of a genteel family seated at Milton in Oxfordshire. He was born December 9th, 1608, and received his education first under a private tutor, afterwards at London, in which his father had settled as a scrivener. At the age of seventeen he was sent to Christ's College, Cambridge, where he made a great progress in all parts of academical learning. In 1628 he proceeded A. B., having performed his exercise for it with great applause. His father designed him for the church; but young Milton's attachment to the muses was so strong that it became impossible to engage him in any other pursuit. In 1632 he took the degree of A. M., and retired to the residence of his parents at Horton, near Colnbrook, in Bucks, where he enriched his mind with the choicest stores of Grecian and Roman literature; and wrote his poems of Comus, L'Allegro, Il Penseroso, and Lycidas. About five years afterwards he travelled into France and Italy, and at Paris became acquainted with the celebrated Grotius. Upon his return he set up an academy in Aldersgate-Street, London. In 1641 he began to write in defence of the Presbyterian party; and in 1642 he married the daughter of Richard Powel esq. of Forest Hill, in Oxfordshire; who being a zealous royalist she was soon advised to return to her relations; which so incensed her husband that he resolved never to take her again, and wrote and published several tracts in defence of the Doctrine and Discipline of Divorce. He also paid his addresses to another lady; but this incident proved the means of a reconciliation with Mrs. Milton, who purposely threw herself in his way at the house of a mutual relation, and on her knees entreated and received his forgiveness. This affecting incident made a deep impression on Milton's sensibility, and enabled him to paint to the life the beautiful scene in his Paradise Lost, b. x. v. 940; where, describing Adam's feelings, he says,

> Soon his heart relented
> Towards her, his life so late and sole delight,
> Now at his feet submissive in distress.

In 1644 he wrote his Tract upon Education and the restraint on the liberty of the press being continued by act of parliament, he wrote boldly and nobly against that restraint. In 1645 he published his juvenile poems; and about two years after, on the death of his father, he took a smaller house in High Holborn, the back of which opened into Lincoln's Inn Fields. Here he quietly prosecuted his studies till the death of Charles I., on which occasion he published his Tenure of Kings and Magistrates in justification of the fact. He was now taken into the service of the commonwealth, and made Latin secretary to the council of state, who resolved neither to write to foreign princes, nor to receive any answers, except in the Latin tongue, which was common to them all. The famous Εικων Βασιλικη coming out about the same time, Milton wrote and published his Iconoclastes the same year. It was also, by order of his masters, backed by the reward of £1000, that, in 1651, he published his celebrated piece entitled Pro Populo Anglicano Defensio, A Defence of the People of England, in answer to Salmasius's Defence of the King; which work spread his fame over all Europe. He now dwelt in a pleasant house, with a garden, in Petty France, Westminster. In 1652 he buried his wife, who died not long after the delivery of her fourth child; and about the same time lost his eye-sight by a gutta serena, which had been growing upon him many years. In 1653 Cromwell took the reins of government into his own hands, but retained Milton in his office. His leisure hours he employed in prosecuting his studies; wherein he was so far from being discouraged by the loss of his sight that he even conceived hopes this misfortune would add new

vigor to his genius, which, in fact, seems to have been the case. Thus animated, he again ventured upon matrimony; and married the daughter of captain Woodcock of Hackney, who died in childbed about a year after. On the deposition of the protector, Richard Cromwell, and on the return of the long parliament, Milton being still continued secretary, he appeared again in print, pleading for a further reformation of the laws relating to religion; and, during the anarchy that ensued, he drew up several schemes for re-establishing the commonwealth, exerting all his abilities to prevent the return of Charles II. England's destiny, however, and Charles's good fortune, prevailing, Milton retired to a friend's house in Bartholomew Close. A prosecution was intended against him; but the just esteem to which his admirable genius and extraordinary accomplishments entitled him, had raised him so many friends, even among those of the opposite party, that he was included in the general amnesty. This storm over, he married his third wife, Elizabeth, daughter of Mr. Minshull, a Cheshire gentleman; and, not long after, he took a house in the Artillery Walk. This was his last stage, where he resided longer than he had done any where. He now applied himself to finish his grand work, Paradise Lost; one of the noblest poems that ever were produced by human genius. It was published in 1667, and his Paradise Regained in 1670. After this he published many pieces in prose; for which we refer our readers to Millar's edition of his whole works in 2 vols. 4to. 1753. This great man died at his house in Bunhill Fields, November 10th, 1674, in his sixty-sixth year. A monument was erected to his memory in 1737, in Westminster Abbey, by Mr. Benson. His person was remarkably handsome, but his constitution was tender, and by no means equal to his incessant studies. Though he had lost great part of his fortune at the Restoration, yet he died worth £1500 in money, beside household goods. He left behind him three daughters, whom he had by his first wife; the youngest of whom was married and had ten children. Mr. Walpole pays as high a compliment to Milton's taste and genius in gardening as the public in general have allowed to his merits in poetry. His remains were interred in the church of Cripplegate, where the elder Samuel Whitbread has erected a monument to his memory. In 1750 the masque of Comus was performed for the benefit of one of his grand-daughters, named Foster, then in a very humble situation.

In 1825 was published his Treatise on Christian Doctrine in Latin and English, 4to. found among the state papers by Mr. Lemon. With it were found corrected copies of Milton's foreign despatches, and several papers relating to the popish trials and rye-house plots. The whole was wrapped in an envelope, addressed 'To Mr. Skinner, Merchant,' the well known friend of the poet. The authenticity of the MS. appears indeed unquestionable: it attests the Arianism of its great author; defends the sentiments he is well known to have adopted on the subject of divorce; advocates polygamy, anthropomorphitism (which Mr. Locke has somewhere said to be almost confined to the ignorant), the eternity of matter, and the abrogation of the Sabbath. His Latin style is always easy, often beautiful; the translation undertaken by order of his majesty (Geo. IV.) was made by Mr. Sumner, a royal chaplain. On the whole the work has disappointed the admirers of Milton. It has few claims to originality of thought or expression; was looked for with avidity, but will ever be read, we are persuaded, with difficulty by those who are at all acquainted with the subjects on which he writes, and presents to our view the melancholy exhibition of a great prostrate intellect struggling in the fetters of various and contradictory systems of theology—to make a worse.

MILTON, a post town of Saratoga county, New York, thirty miles north of Albany. Population 2763. It contains valuable mills, a woollen manufactory, and five houses for public worship.

MILTON, a market town of Kent, near Sittingbourn and the isle of Sheppey, six miles northwest of Feversham, and forty east of London; also called Middleton from its situation near the middle of the county, between Deptford and the Downs. The kings of Kent had a castellated palace here, which stood below the church, but was burnt down in Edward the Confessor's time by earl Godwin. The church stands a mile off. On approaching the town up the Thames, by east Swale, it seems hid among the creeks; yet it is large, and has a considerable market on Saturday, and a fair 24th July. The oysters taken hereabouts are the most famous in Kent. It is governed by a portreeve, and lies fourteen miles north-east of Maidstone.

MILTON, a town of Kent, a mile on the east side of Gravesend, incorporated with it in the reign of queen Elizabeth under a portreeve, jurats, &c. King Henry VIII. raised a platform here for the defence of both towns and the river. It has a fair 25th January.

MILVIUS, MOLVIUS, or MULVIUS, PONS, a bridge on the Tiber, two miles from Rome, on the Via Flaminia, built by Æmilius Scaurus the censor, in the time of Sylla, and repaired by Augustus. From this bridge the ambassadors of the Allobroges were brought back to Rome by Cicero's order, and made a discovery of Catiline's conspiracy.—Sallust. Near it Maxentius was defeated by Constantine.—Eutropius.

MILVUS, in ornithology, a species of falco.

MI'ME, *n. s.* & *v. n.*
MI'MER, *n. s.*
MIME'TIC, *adj.*
MIM'IC, *n. s. adj.* & *v. a.*
MIM'ICAL, *adj.*
MIM'ICALLY, *adv.*
MIM'ICRY, *n. s.*
MIMOG'RAPHER.

Fr. *mime;* Ital. *mimo;* Lat. *mimus, mimicus;* Gr. *μιμος.* Mime, mimer, and mimic, alike mean a jester, antic imitator, or buffoon: to mime or mimic is to imitate as a buffoon; ridicule by burlesque imitation: mimic, as an adjective, signifies imitative, resembling: mimetic, having the faculty of mimicing: mimicry, burlesque or ridiculous imitation: a mimographer is a word which we find only in Johnson for a writer of farces.

Think'st thou, *mime,* this is great? or that they strive,
Whose noise shall keep thy *miming* most alive,
Whilst thou dost raise some player from the grave,
Out-dance the babion, or out-boast the brave?

Ben Jonson.

Man is of all creatures the most *mimical* in gestures, styles, speech, fashion, or accents.
Wotton on Education.

Let us grant these faculties so fixed upon any nation, that all our water must necessarily be fetched at their well, and add unto these a few waste compliments and *mimical* courtesies, which must needs be put into the match of our ordinary travel.
Bp. Hall.

Jugglers and dancers, anticks, mummers, *mimers*.
Milton.

In reason's absence *mimick* fancy wakes
To imitate her; but misjoining shapes,
Wild work produces oft, and most in dreams.
Id.

Is not this plainly the life of a child, that is ever busy, yet never hath any thing to do? or the life of that *mimical* brute which is always active in playing uncouth and unlucky tricks. *Barrow.*

Singers and dancers entertained the people with light songs and *mimical* gestures, that they might not go away melancholy from serious pieces of the theatre. *Dryden's Juvenal.*

Morpheus expressed
The shape of man and imitated best;
The walk, the words, the gesture, could supply,
The habit *mimick*, and the mien belye. *Id.*

A *mimical* daw would needs try the same experiment; but his claws were shackled.
L'Estrange.

By an excellent faculty in *mimickry*, my correspondent tells me, he can assume my air, and give my taciturnity a slyness which diverts more than any thing I could say. *Spectator.*

Like poor Andrew I advance,
False *mimick* of my master's dance:
Around the cord awhile I sprawl,
And thence, though slow, in earnest fall. *Prior.*

Who would with care some happy fiction frame,
So *mimicks* truth, it looks the very same. *Granville.*

The busy head with *mimick* art runs o'er
The scenes and actions of the day before. *Swift.*

I called moreover into action my *mimetic* powers, and, before the expiration of my eleventh year, was able to imitate, with no small share of success, the tone and manner of the writing usher in pronouncing 'Very well, master Simkins, I shall sartinly get you vipt for dartying on your breeches.' *Canning.*

MIMI, MIMES, from μιμεομαι, to imitate; in the ancient comedy, buffoons or mimics, who entertained the people by imitating and caricaturing certain characters. There were, on the Roman stage, female performers of this kind called Mimæ. Some of the mimi acted their parts to the sound of the tibia; these they called mimauli.

MIMI were also a kind of farces or ludicrous comedies generally performed by one person. They had no acts, nor any exordium. They were introduced upon the Roman stage long after comedy and tragedy had arrived at perfection. The actor wore no mask, but smeared his face with soot, was dressed in lambskin, wore garlands of ivy, and carried a basket of flowers and herbs in honor of Bacchus, and diverted the audience with ridiculous tricks and dances. They afterwards underwent many alterations. See PANTOMIME.

MIMNERMUS, an ancient poet and musician of Smyrna, who flourished about A. A. C. 590, and was contemporary with Solon. Athenæus says he invented pentameter verse. His elegies, of which only a few fragments are preserved, were so much admired, that Horace preferred them to those of Callimachus. He composed one, as we learn from Pausanias, upon the battle between the people of Smyrna and the Lydians, under Gyges: and another in elegiac verse, quoted by Strabo, entitled Nanno. With respect to amorous poetry, Horace celebrates his abilities Ep. vi. lib. i. v. 65; and Propertius (lib. i. el. 9, v. 11) says,

Plus in amore valet Mimnermi versus Homero.

MIMOSA, the sensitive plant, a genus of the polygamia order, and monœcia class of plants, natural order thirty-third, lomentaceæ: HERMAPHRODITE. CAL. quinquedentate: COR. quinquefid; stamina five or more; pistil one, and a legumen: MALE CAL. quinquedentate: COR. quinquefid, with five, ten, or more stamina. The name mimosa signifies mimic, and is given to this genus on account of the sensibility of the leaves, which seem to mimic the motion of animals. To this genus Linnæus joins many of the acacias, and it comprises many different species, all natives of warm climates. Of the sorts cultivated in our stoves, &c., some are of the shrub and tree kind, and two or three are herbaceous perennials and annuals. The sensitive plants are exceedingly curious in the very singular circumstance of their leaves receding rapidly from the touch, and running up close together; and in some sorts the foot-stalks are affected, so as instantly to fall downward as if fastened by hinges; which last are called humble sensitives. They have all winged leaves, each wing consisting of many small pinnæ. In the Systema Vegetabilium this genus, including the mimosas properly so called, and the acacias, is divided into several sections, distinguished by the figure, situation, and arrangement of the leaves; as simple, simply pinnated, bigeminous and tergeminous, conjugate and pinnated, doubly pinnated. The following are the most remarkable species:—

1. M. arborea, the wild tamarind tree, is common in all the woodlands in Jamaica. It rises to a considerable height, and is proportionably thick. The timber is excellent, and serves many purposes in rural economy; it is of the color of cedar, pretty hard, and takes a good polish. The leaves are numerous; the flowers globular and white. The pods are about a foot long, of a fine scarlet color; when ripe they open and become twisted. The seeds then appear: they are oblong, smooth, and of a shining black and quite soft. The leaves, flowers, and pods exhibit a singular and beautiful contrast. It is raised in hot-houses in this country, but might be made to grow in the open air.

2. M. asperata, the Panama sensitive plant. Of this curious species, which has been well described by Dr. Browne, there is a good figure in the Reliquiæ Houstonianæ, published by Sir Joseph Banks. It grows in moist places, and by the sides of rivulets, in Jamaica. It seldom rises above three feet, but its slender branches extend considerably on the neighbouring bushes. It is armed with crooked sharp spines so thickly set on the trunk, branches, and leaves,

that there is no touching it with safety. 'But it is very beautiful: the flowers are yellow and globular, growing at the extremity of the branches. The pods are hairy, brown, and jointed, each containing a small, flat, and brown seed. The leaves are numerous, small, and winged, and very irritable, contracting with the least touch, and remaining so for several minutes after. This species would form a good hedge round a garden, and, by being trimmed now and then, may be easily kept from spreading.

3. M. catechu grows only to about the height of twelve feet, and one foot in diameter; it is covered with a thick rough brown bark, and, towards the top, divides into many close branches; the leaves are bipinnated, or doubly winged, and are placed alternately upon the younger branches. The partial pinnæ are nearly two inches long, and are commonly from fifteen to thirty pair, having small glands inserted between the pinnæ; each wing is usually furnished with forty pairs of pinnulæ or linear lobes, beset with short hairs; the spines are short, recurved, and placed in pairs at the bases of each leaf; the flowers are hermaphrodite and male, and stand in close spikes, which arise from the axillæ of the leaves, and are four or five inches long: the calyx is tubular, hairy, and divides at the limb into five oval pointed segments; the corolla is monopetalous, whitish, and of the same form as the calyx, but twice its length; the filaments are numerous, capillary, double the length of the corolla, adhering at the base of the germen, and crowned with roundish antheræ; the germen is oval, and supports a slender style, which is of the length of the filaments, and terminated by a simple stigma; the fruit or pod is lance-shaped, brown, smooth, compressed, with an undulated thin margin; it contains six or eight roundish flattened seeds, which produce a nauseous odor when chewed. From this tree, which grows plentifully on the mountains of Hindostan, where it flowers in June, is produced the officinal drug long known in Europe by the name of terra japonica.

4. M. cinerea, and M. pinnata, cashew bushes. These species are common about Kingston and Spanish town, Jamaica, and rise by slender trunks to about twenty feet. Dr. Roxburgh, of Madras, found the lac insect on these species.

5. M. cornigera, the horned Mexican mimosa, or great horned acacia, has a shrubby upright deformed stem, branching irregularly, armed with very large, horn-like, white spines, by pairs, connated at the base; bipinnated leaves thinly placed; and flowers growing in spikes. This species is esteemed for the oddity of its large spines, resembling the horns of animals, and which are often variously wreathed, twisted, and contorted.

6. M. cornuta, the horned ergett, a native of Abyssinia, described by Mr. Bruce. The flower very much resembles that of the acacia vera in size and shape, excepting that it is attached to the branch by a strong woody stalk of considerable length, which grows out at the bottom of the branch bearing the leaves, and is sheltered as in a case by the lower part of it. The branches are all covered with short, strong, and sharp-pointed thorns, having their points inclined backwards towards the root. The pods are covered with a prickly kind of hair, which easily rubs off with the fingers, sticks to them, and gives a very uneasy sensation. They have thirteen divisions, in each of which are three hard, round, and shining seeds, of a dusky brown color.

7. M. farnesiana, the fragrant acacia, grows in woodlands and waste lands in Jamaica; rising twenty-five or thirty feet, with suitable thickness. The bark of the trunk is brown and scaly, the branches are alternate. It is adorned with bipinnated leaves of a bright green color, and yellow globular flowers from the axillæ, of a fragrant smell. The pods are about three inches long, and half an inch broad: they are of a light brown color, smooth, compressed, and contain five or six smooth flat seeds. Formerly the flowers of this tree were used as an ingredient in the theriaca andromachi of the old dispensatories. It is sometimes planted for a hedge round enclosures; and the timber, though small, is useful in rural economy.

8. M. latifolia, shag-bark, or white wild tamarind. This excellent timber tree is very common in Jamaica, and rises to a moderate height and good thickness. The trunk is rough and scaly: the leaves are numerous, of a rhomboidal figure, and yellowish cast. The flower-spikes are from the axillæ; their color is yellow. The seed vessels are flat, jointed, and twisted. The seeds are of the bigness of a vetch, white, and finely streaked with blue.

9. M. nilotica, the true Egyptian acacia, rises to a greater height than the preceding: the bark of the trunk is smooth, and of a gray color; that of the branches has commonly a purplish tinge: the leaves are bipinnated, and placed alternately: the partial pinnæ are opposite, furnished with a small gland between the outermost pair, and beset with numerous pairs of narrow elliptical pinnulæ; the spines are long, white, spreading, and proceed from each side of the base of the leaves: the flowers are hermaphrodite and male; of a globular shape, and standing four or five together, upon slender peduncles, which arise from the axillæ; the calyx is small, bell-shaped, and divided at the mouth into five minute teeth; the corolla consists of five narrow yellowish segments: the filaments are numerous, capillary, and furnished with roundish yellow antheræ. the germen is conical, and supports a slender style, crowned with a simple stigma: the fruit is a long pod, resembling that of the lupin, and contains many flattish brown seeds. It is a native of Arabia and Egypt, and flowers in July. Though this species grows in great abundance over the vast extent of Africa, yet gum arabic is produced chiefly by those trees which are situated near the equatorial regions; and in Lower Egypt the solar heat is never sufficiently intense for this purpose. The gum exudes in a liquid state from the bark of the trunk and branches of the tree, like the gum often produced upon the cherry trees, &c., in this country: and by exposure to the air it soon acquires solidity. In Senegal it begins to flow when the tree first opens its flowers, and continues during the rainy season till December, when it is collected for the first

time. Another collection of it is made in March, from incisions in the bark. Gum arabic is now usually imported from Barbary in large casks. The various figures which it assumes depend upon accidental circumstances during its transudation and concretion. The pale yellowish gum is most esteemed; pieces which are large, rough, of a roundish figure, and of a brownish or reddish hue, are less pure, being produced from a different species; but the Arabian and Egyptian gum is commonly intermixed with pieces of this kind. Gum arabic does not admit of solution by spirit or oil; but in twice its quantity of water it dissolves into a mucilaginous fluid, of the consistence of a thick syrup; and in this state answers many useful pharmaceutical purposes, by rendering oily, resinous, and pinguious substances, miscible with water. It is preferred to most other gums as a demulcent in catarrhal affections, &c., and has been generally employed in cases of ardor urinæ and strangury. See CHEMISTRY and MEDICINE.

10. M. Pernambucana, the Pernambuca slothful mimosa, with unshrubby, procumbent, unarmed stems, branching two or three feet around; bipinnated leaves of three or four pairs of short winged foliola; and, at the axillæ drooping spikes of pentandrous flowers, the lower ones castrated. This species recedes very slowly from the touch, only contracting its pinnæ a little when smartly touched; hence the name slothful.

11. M. plena, the annual, or double-flowered sensitive mimosa, rises with an herbaceous, erect, round, unarmed stem, closely branching and spreading every way, three or four feet high; bipinnated leaves of four or five pairs of winged lobes, of many pairs of pinnæ; and at the axillas and termination of the branches, spikes of yellow pentandrous flowers, the lower ones double; succeeded by short broad pods. It is only sensitive in the foliola, but extremely sensible of the touch or air.

12. M. pudica, the bashful humble plant, rises with an undershrubby, declinated, prickly stem, branching two or three feet around, armed with hairy spines; pinnated, digitated leaves, each leaf being of five or more long folioles, attached by their base to a long foot-stalk, and spread out above like the fingers of a hand; and at the sides and ends of the branches roundish heads of greenish white flowers, succeeded by small jointed prickly pods. This is truly of the humble sensitive kind: for by the least touch the leaves instantly recede, contract, close, and with the foot-stalk quickly decline downward.

13. M. punctata, the punctuated sensitive mimosa, rises with a shrubby, upright, taper, spotted, unarmed stem, branching erectly five or six feet high; bipinnated leaves, of four or five pairs of long-winged folioles, having each about twenty pairs of pinnæ; and at the axillas and termination of the branches oblong spikes of yellowish decandrous flowers, the inferior ones castrated; succeeded above by oblong seed-pods. This sort, though naturally shrubby and perennial in its native soil, yet in this country sometimes decays in winter. It is only sensitive in the foliola, but quick in the motion.

14. M. quadrivalvis, the perennial, or quadrivalve humble mimosa, has herbaceous, slender, quadrangular, prickly stems, branching and spreading all around, armed with recurved spines; bipinnated leaves of two or three pairs of winged lobes, having each many pinnæ; and at the axillas globular heads of purple flowers succeeded by quadrivalvular pods. Both leaves and foot-stalks recede from the touch.

15. M. scandens, cacoons, mafootoo wyth, or the climbing mimosa. This species is frequent in all the upland valleys and woodlands on the north side of Jamaica. It climbs up the tallest trees, and spreads itself in every direction by its cirrhi or claspers, so as to form a complete arbor, and to cover an English acre from one root. This has a bad effect on the trees or bushes so shaded. Light, air, and rain, being shut out, the leaves drop off, the tree gradually rots, and the limbs fall down by the weight o, this parasite. The roots run superficially under the ground or herbage. The trunk is seldom thicker than a man's thigh, and sends off many branches, with numerous shining green leaves, each of which terminates in a tendril or clasper, that serves to fasten it to trees or bushes. The flower-spikes are from the axillæ; they are slender, and the florets small and numerous. The pod is perhaps the largest and longest of any in the world; being sometimes eight or nine feet long, five inches broad, jointed, and containing ten or fifteen seeds, which are brown, shining, flattened, and very hard, and called cacoons. They are mentioned in the Philosophical Transactions as being thrown ashore on the Hebrides and Orkneys. This happens in the following manner: the seeds or beans fall into the rivers, and are conveyed to the sea. The trade winds carry them westward till they fall into the gulf stream, which drives them northwards along the coast of America, and Bahama Islands. As the winds blow frequent and strong from America, these seeds are driven eastward, till they are thrown ashore and left with the tide as aforesaid. This bean, after being long soaked in water, is boiled and eaten by some negroes; but the chief use made of it is for a sort of snuff-box.

16. M. Senegalensis, the Senegal mimosa, is a native of Guinea, and was some time ago introduced into Jamaica. Dr. Wright saw both this and the nilotica, of the size of a cherry-tree, growing at Dr. Paterson's in the parish of Hanover, Jamaica. The flowers are globular, yellow, and fragrant. The pods are brown, and of the size of a goose-quill. The tree, on being wounded, exudes gum-arabic, though in a smaller quantity, and less transparent, than that of the shops, which is obtained from the nilotica.

17. M. sensitiva, the common humble sensitive plant, rises with an undershrubby prickly stem, branching six or eight feet high, armed with crooked spines; conjugated, pinnated leaves, with bijugated partial lobes or wings, having the inner ones least, each leaf on a long foot-stalk; and at the sides and ends of the branches many purple flowers in roundish heads, succeeded by broad, flat, jointed pods, in radiated clusters. The leaves and foot-stalks recede from the touch, though not with such facility as in some other species.

18. M. viva, the lively mimosa, or smallest sensitive weed, has many creeping-roots, and spreads itself so as to cover large spots of ground. It rises at most to two inches, has winged leaves, with numerous small pinnæ. The flower is globular, of a bluish color, and grows in clusters from the axillæ; these are followed by little short hairy pods, containing smooth, shining seeds. This is the most sensible of all the mimosas, the pudica not excepted. By running a stick over the plant, a person may write his name, and it will remain visible for ten minutes.

The sensitive plants are well known to possess a kind of motion, by which the leaves and stalks are contracted and fall down upon being slightly touched, or shaken with some degree of violence. The contraction of the leaves and branches of the sensitive plant when touched, is a very singular phenomenon. Different hypotheses have been formed by botanists to explain it; but these have generally been deduced rather from analogical reasonings than from a collection of facts and observations. The following are the most important facts collected upon this curious subject:—It is difficult to touch the leaf of a healthy sensitive plant so delicately that it will not immediately collapse, the foliola or little leaves moving at their base till they come into contact, and then applying themselves close together. If the leaf be touched with a little more force, the opposite leaf will exhibit the same appearance. If a little more force be applied, the partial foot-stalks bend down towards the common foot-stalk, from which they issue, making with it a more acute angle than before. If the touch be more violent still, all the leaves situated on the same side with the one that has been touched will instantly collapse, and the partial foot-stalk will approach the common foot-stalk to which it is attached, in the same manner as the partial foot-stalk of the leaf approaches the stem or branch from which it issues; so that the whole plant, from having its branches extended, will immediately appear like a weeping willow. These motions on the plant are performed by means of three distinct and sensible articulations. The first that of the foliola or lobes to the partial foot-stalk; the second that of the partial foot-stalk to the common one; the third that of the common foot-stalk to the trunk. The primary motion of all is the closing of the leaf upon the partial foot-stalk, which is performed in a similar manner, and by a similar articulation. This, however, is much less visible than the others. These motions are wholly independent on one another. Winds and heavy rains make the leaves of the sensitive plant contract and close; but no such effect is produced from slight showers. At night, or when exposed to much cold in the day, the leaves meet and close in the same manner as when touched, folding their upper surfaces together, and in part over each other like scales of tiles, so as to expose as little as possible of the upper surface to the air. The opposite sides of the foliola, or leaves, do not come close together in the night; for when touched they apply themselves closer together. Dr. Darwin kept a sensitive plant in a dark place for some hours after day-break; the leaves and footstalks were collapsed; and on exposing it to the light, above twenty minutes passed before it was expanded. In August, a sensitive plant was carried in a pot out of its usual place into a dark cave, the motion that it received in the carriage shut up its leaves, and they did not open till twenty-four hours afterwards; at this time they became moderately open, but were afterwards subject to no changes at night or morning, but remained three days and nights with their leaves in the same moderately open state. At the end of this time they were brought out again into the air, and there recovered their natural periodical motions, shutting every night and opening every morning, as naturally and as strongly as if the plant had not been in this forced state; and while in the cave it was observed to be very little less affected with the touch than when abroad in the open air. The great heats of summer, when there is open sunshine at noon, affect the plant in some degree like cold, causing it to shut up its leaves a little, but never in any very great degree. The plant, however, is least of all affected about nine A. M., and that is consequently the properest time to make experiments on it. A branch of the sensitive plant, cut off and laid by, retains yet its property of shutting up and opening in the morning for some days, and it holds it longer if kept with one end in water, than if left to dry more suddenly. The leaves only of the sensitive plant shut up in the night, not the branches; and if it be touched at this time, the branches are affected in the same manner as in the day, shutting up or approaching to the stalk or trunk in the same manner and often with more force. It is of no consequence what the substance is with which the plant is touched; but there is a little spot, distinguishable by its paler color in the articulations of its leaves, where the greatest and nicest sensibility is evidently placed. Du Hamel having observed, about the 15th of September in moderate weather, the natural motion of a branch of a sensitive plant, remarked, that at nine A. M. it formed with the stem an angle of 100°; at noon 112°; at three P. M. it returned to 100°; and after touching the branch, the angle was reduced to 90°. Three-quarters of an hour after it had mounted to 112°; and at eight P. M. it descended again without being touched to 90°. The day after, in finer weather, the same branch at eight A. M. made an angle of 135° with the stem; after being touched, the angle was diminished to 80°; an hour after it rose again to 135°; being touched a second time it descended again to 80°; an hour and a half after it had risen to 145°; and upon being touched a third time descended to 135°, and remained in that position till five P. M., when, being touched a fourth time, it fell to 110°. The parts of the plants which have collapsed, afterwards unfold themselves, and return to their former expanded state. The time required for that purpose varies according to the vigor of the plant, the season of the year, the hour of the day, the state of the atmosphere. Sometimes half an hour is requisite, sometimes only ten minutes. The order in which the parts recover themselves

varies in like manner; sometimes it is the common foot-stalk; sometimes the rib to which the leaves are attached; and sometimes the leaves themselves are expanded, before the other parts have made any attempt to recover their former position. If, without shaking the other smaller leaves, we cut off the half of a leaf or lobe belonging to the last pair, at the extremity or summit of a wing, the leaf cut, and its antagonist, that is to say, the first pair, begin to approach each other; then the second, and so on successively, till all the smaller leaves, or lobes of that wing, have collapsed in like manner. Frequently, after twelve or fifteen seconds, the lobes of the other wings, which were not immediately affected by the stroke, shut; whilst the stalk and its wing, beginning at the bottom, and proceeding in order to the top, gradually recover themselves. If, instead of one of the lesser extreme leaves, we cut off one belonging to the pair that is next the foot-stalk, its antagonist shuts, as do the other parts successively, from the bottom to the top. If all the leaves of one side of a wing be cut off, the opposite leaves are not affected, but remain expanded. With some address, it is possible even to cut off a branch without hurting the leaves or making them fall. The common foot-stalk of the winged leaves being cut as far as three-fourths of its diameter, all the parts which hang down collapse, but quickly recover without appearing to have suffered any considerable violence by the shock. An incision being made into one of the principal branches to the depth of half the diameter, the branches betwixt the section and the root will fall down; those above the incision remain as before, and the lesser leaves continue open; but this direction is soon destroyed, by cutting off one of the lobes at the extremity. A whole wing being cut off with precaution, near its insertion into the common foot-stalk, the other wings are not affected by it, and its own lobes do not shut. No motion ensues from piercing the branch with a needle or other sharp instrument. If the end of one of the leaves be burned with the flame of a candle, or by a burning glass, or by touching it with hot iron, it closes up in a moment, and the opposite leaf does the same, and after that the whole series of leaves on each side of the partial or little foot-stalk; then the foot-stalk itself; then the branch or common foot-stalk; all do the same, if the burning has been in a sufficient degree. This proves that there is a very nice communication between all the parts of the plant, by means of which, the burning, which is only applied to the extremity of one leaf, diffuses its influeuce through every part of the shrub. If a drop of aquafortis be carefully laid upon a leaf of the sensitive plant, so as not to shake it in the least, the leaf does not begin to move till the acrid liquor corrodes the substance of it; but at that time, not only that particular leaf, but all the leaves placed on the same foot-stalk, close themselves up. The vapor of burning sulphur has also this effect on many leaves at once, according as they are more or less exposed to it; but a bottle of very acrid and sulphureous spirit of vitriol, placed under the branches unstopped, produces no such effect. Wetting the leaves with spirit of wine has been observed also to have no effect, nor the rubbing oil of almonds over them, though this last application destroys many plants. From the preceding experiments the following conclusions may be fairly drawn:—The contraction of the parts of the sensitive plant is occasioned by an external force, and the contraction is in proportion to the force. All bodies which can exert any force affect the sensitive plant; some by the touch or by agitation, as the wind, rain, &c.; some by chemical influence, as heat and cold. Touching or agitating the plant produces a greater effect than an incision or cutting off a part, or by applying heat or cold. Attempts have been made to explain these curious phenomena. Dr. Darwin, in the notes to his Botanic Garden, lays it down as a principle, that 'the sleep of animals consists in a suspension of voluntary motion; and, as vegetables are subject to sleep as well as animals, there is reason to conclude,' says he, 'that the various actions of closing their petals and foliage may be justly ascribed to a voluntary power; for without the faculty of volition sleep would not have been necessary to them.' Whether this definition of sleep when applied to animals be just, we shall not enquire; but it is evident that the supposed analogy between the sleep of animals and the sleep of plants has led Dr. Darwin to admit this astonishing conclusion, that plants have volition! As volition presupposes a mind or soul, it were to be wished that he had given us some information concerning the nature of a vegetable soul, which can think and will. We suspect, however, that this vegetable soul will turn out to be a mere mechanical or chemical one; for it is affected by external forces uniformly in the same way, its volition is merely passive, and never makes any successful resistance against those causes by which it is influenced.

MIMULUS, in botany, monkey flower, a genus of the angiospermia order, belonging to the didynamia class of plants; natural order fortieth, personatæ.

MINA, or MANEH, in Jewish antiquity, a species of money, which properly signifies one part or ounce. This word occurs in the books of Kings, Chronicles, Ezra, and Ezekiel. This last prophet tells us (xlv. 12), that the minah or maneh was valued at sixty shekels; which in gold make of our English money about £54 15s. and in silver, almost £7.

MINA, in Grecian antiquity, or the attic mina, which is probably that mentioned in the books of the Maccabees and in the New Testament, is valued at 100 drachmæ, or about £2 17s. sterling. There was also a lesser mina, valued at seventy-five drachmæ.

MINAB, a flourishing sea-port of Kirwar, on the Persian Gulf; the territory around abounds in dates, and supplies the neighbouring country with grain. Forage is so plentiful that, during the dry season, the cattle of the adjacent districts are sent in great numbers here to pasture. Long. 56° 40′ E., lat. 27° 8′ N.

MINA'CIOUS, *adj.*
MINAC'ITY, *n. s.*
MIN'ATORY, *adj.*
} Lat. *minax*, *minor* Threatening; abounding in threats; this

both the adjectives signify: minacity, proneness to threaten. Words seldom used.

The king made a statute monitory and *minatory*, towards justices of peace, that they should duly execute their office, inviting complaints against them.

Bacon's Henry VII.

MIN'ARET. Fr. *minaret*; Pers. *minar*. A round tower, generally encircled by balconies, and erected near the mosques in Mohammedan countries, from which the *Muezzin* summons the people to prayer, and announces the hours; bells not being in use among the Mussulmans.

MINAS GERAES, a province of Brasil, extending from north to south from 600 to 700 miles, and about the same distance east and west. It is bounded on the north by Bahia, on the west by Goyaz, and on the south by the Paraibuna, which divides it from the capitania of Rio de Janeiro. From Espiritu Santo and the coast it is separated by an immense chain of mountains, and a country little known. It contains the four districts of St. Joao del Rey, Sabara, Villa Rica, and Cerro do Fio, which produced much more gold a few years after they were discovered than in modern times; though, according to Mr. Mawe, in 1809 the royal fifth amounted to 150 arrobas of 32 lbs. each, or about £1,100,000. Abundance both of gold and diamonds are still, therefore, found; besides which the country yields platina, iron, antimony, bismuth, and chromate of lead. It is rich also in sugar, cotton, wheat, and almost all sorts of grain. In the woods the finest trees are frequently destroyed by the creeping plants; but they abound with trees of various quality, and fit for all purposes. Aromatic shrubs, and occasionally the mulberry and silk-worm, are found, but the latter are not well managed. The palma Christi grows spontaneously; beans, peas, and pulse in general are also fine, as well as pumpkins and cabbages. Here also the rose is extremely fragrant, and in bloom all the year. Varieties of the passion-flower, pinks, carnations, with numberless other flowers, grow in great profusion. The regular military establishment was at a late period 1400 cavalry. Their principal station is Villa Rica. They escort diamonds and treasure to the capital. The regiment enjoys a high reputation, so that numbers are continually offering to enlist. Besides this force there is a militia, in which all the male inhabitants of the capitania are enrolled. The population is estimated at 360,000, of whom 200,000 are negroes; the Indians are not included, but they are not considered numerous.

MINCE, *v. a.* & *n. s.* } Fr. *mincer*. To cut
MINC'INGLY, *adv.* } into small pieces; hence to speak cautiously, or communicate a small portion of information at a time; to speak affectedly: as a neuter verb, to walk in short steps; to walk delicately or affectedly: mincingly, in small parts; not fully or largely.

By her side did sit the bold Sansloy,
Fit mate for such a *mincing* minion,
Who in her looseness took exceeding joy.

Faerie Queene.

Justice requireth nothing *mincingly*, but all with pressed and heaped, and even over-enlarged measure.

Hooker.

She saw Pyrrhus make malicious sport,
In *mincing* with his sword her husband's limbs.

Shakspeare.

Iago,
Thy honesty and love doth *mince* the matter,
Making it light to Cassio. *Id. Othello.*

These gifts,
Saving your *mincing*, the capacity
Of your soft cheveril conscience would receive,
If you might please to stretch it. *Shakspeare.*

I'll turn two *mincing* steps
Into a manly stride. *Id. Merchant of Venice.*

With a good chopping knife *mince* the two capons as small as ordinary *minced* meat. *Bacon.*

A good schoolmaster *minces* his precepts for children to swallow; hanging clogs on the nimbleness of his own soul, that his scholars may go along with him. *Fuller.*

I'll try to force you to your duty:
For so it is, however you *mince* it,
Ere we part I shall evince it. *Hudibras.*

If, to *mince* his meaning, I had either omitted some part of what he said, or taken from the strength of his expression, I certainly had wronged him.

Dryden.

The reeve, miller, and cook, are as much distinguished from each other, as the *mincing* lady prioress and the broad-speaking wife of Bath.

Id. Fables.

What means the service of the church so imperfectly, and by halves, read over? What makes them *mince* and mangle that in their practice, which they could swallow whole in their subscriptions?

South's Sermons.

These, seeing no where water enough to effect a general deluge, were forced to *mince* the matter, and make only a partial one of it, restraining it to Asia.

Woodward.

Revive the wits;
But murder first, and *mince* them all to bits.

Dunciad.

A harlot form soft sliding by,
With *mincing* step, small voice, and languid eye.

Id.

MINCH, an arm of the North Sea, which separates the Isle of Sky from the Long Island.

MINCHA, in the Jewish customs, offerings of meal, cakes, or biscuits, made in the temple. The LXX have sometimes preserved this word in their translation; but, instead of mincha, they read manaa, which doubtless was the received pronunciation in their time. Manaa is used in the same sense, in Baruch i. 10, Levit. ii. 3, &c. See the Septuagint of Jerem. xvii. 26; Dan. ii. 46; 2 Kings viii. 5, 9, xvii. 7, xx. 12; 2 Chron. vii. 7; Nehem. xiii. 5, 9, &c.

MINCIO, a river of Italy, flowing southward from the Garda Lake, and which, after forming the marshes that surround Mantua, falls into the Po, eight miles below that city. Its banks are uncommonly fertile, and celebrated for the descriptions of their scenery by Virgil. Several streams flow from the mountains into the lake; that, commonly considered as the commencement of the Mincio, is the Sarca, rising in the south of the Tyrol.

MIND, *n. s.*, *v. a.* & *v. n.* } Sax. mynd ȝemind; Goth. and
MIND'ED, *adj.* } Swed. *mod*; Dan.
MIND'FUL, } *minde*. Intellect;
MIND'FULLY, *adv* } intellectual power
MIND'LESS, *adj.* } or capacity; hence
MIND'STRICKEN,

thought, sentiment, opinion, judgment, memory: to mind is to mark or heed; attend; put in remembrance; and, as a neuter verb, to incline; be disposed: minded is disposed; inclined; affected: mindful, attentive; careful; having memory (taking of); mindless, without intellectual powers; inattentive; heedless; stupid: mind-stricken, violently moved or affected in mind.

Hast thou a wife after thy *mind?* forsake her not. *Ecclus.*

I am not *high-minded,* I have no proud looks. *Psalm.*

Be of the same *mind* one towards another. *Rom.* xii. 16.

He had been so *mind-stricken* by the beauty of virtue in that noble king, though not born his subject, he ever professed himself his servant. *Sidney.*

His mournful plight is swallowed up unwares,
Forgetful of his own, that *minds* another's cares. *Spenser's Faerie Queene.*

When one of them *mindeth* to go into rebellion, he will convey away all his lordships to feoffees in trust. *Spenser.*

Our question is, Whether all be sin which is done without direction by scripture, and not whether the Israelites did at any time amiss, by following their own *minds,* without asking counsel of God? *Hooker.*

I am a very foolish, fond old man;
I fear I am not in my perfect *mind.* *Shakspeare.*

Being so hard to me that brought your *mind,*
I fear she'll prove as hard to you in telling her *mind.* *Id.*

I will have nothing else but only this;
And now methinks I have a *mind* to it. *Id.*

Let me be punished, that have *minded* you
Of what you should forget. *Id. Winter's Tale.*

We come to know
How you stand *minded* in the weighty difference
Between the king and you. *Id. Henry VIII.*

Cursed Athens, *mindless* of thy worth,
Forget now thy great deeds, when neighbour states,
But for thy sword and fortune, trod upon them. *Shakspeare.*

This word being often used for the soul giving life, is attributed abusively to madmen, when we say that they are of a distracted *mind,* instead of a broken understanding: which word, *mind,* we use also for opinion; as, I am of this or that *mind:* and sometimes for men's conditions or virtues; as, he is of an honest *mind,* or a man of a just *mind:* sometimes for affection; as, I do this for my *mind's* sake; sometimes for the knowledge of principles, which we have without discourse; oftentimes for spirits, angels, and intelligences, &c. *Raleigh.*

They had a *mind* to French Britain; but they have let fall their bit. *Bacon's War with Spain.*

The king knows their disposition; a small touch will put him in *mind* of them. *Bacon.*

A man who cannot *mind* his own business, is not to be trusted with the king's. *Saville.*

God first made angels bodiless, pure *minds;*
Then other things, which *mindless* bodies be:
Last, he made man. *Davies.*

O envy, the corrosive of all ill *minds,* and the root of all desperate actions. *Bp. Hall's Contemplations.*

The proverbs of several nations were much studied by Bishop Andrews, and the reason he gave was, because by them he knew the *minds* of several nations, which is a brave thing. *Selden.*

I acknowledge the usefulness of your directions, and I promise you to be *mindful* of your admonitions. *Hammond.*

We say that learning's endless, and blame fate
For not allowing life a longer date,
He did the utmost bounds of knowledge find,
He found them not so large as was his *mind.* *Cowley.*

Who this observes, may in his body find
Decrepit age, but never in his *mind.* *Denham.*

Waller coasted on the other side of the river, but at such a distance that he had no *mind* to be engaged. *Clarendon.*

Sudden *mind* arose
In Adam, not to let the occasion pass,
Given him by this great conference, to know
Of things above this world. *Milton's Paradise Lost.*

Not then mistrust, but tender love enjoins,
That I should *mind* thee oft, and *mind* thou me. *Milton.*

Whose fellowship therefore unmeet for thee,
Good reason was thou freely should'st dislike,
And be so *minded* still. *Id. Paradise Lost.*

Somewhat always of suspicion and ill opinion will stick in the *minds* of those who have given ear to slander. *Barrow.*

Truth is the special ornament of our *minds,* decking it with a graceful pleasant lustre. *Id.*

If, in the raving of a frantic muse,
And *minding* more his verses than his way,
Any of these should drop into a well. *Roscommon.*

All the arguments to a good life will be very insignificant to a man that hath a *mind* to be wicked, when remission of sins may be had upon such cheap terms. *Tillotson's Sermons.*

If men were *minded* to live virtuously, to believe a God would be no hindrance to any such design, but very much for its advancement. *Tillotson.*

I thought the eternal *mind*
Had made us masters. *Dryden.*

These, and more than I to *mind* can bring,
Menalcus has not yet forgot to sing. *Id.*

Cease to request me; let us *mind* our way;
Another song requires another day. *Id.*

This *minds* me of a cobbling colonel. *L'Estrange.*

These men are of the *mind,* that they have clearer ideas of infinite duration than of infinite space, because God has existed from all eternity; but there is no real matter co-extended with infinite space. *Locke.*

I shall only *mind* him, that the contrary supposition, if it could be proved, is of little use. *Id.*

Pyrrhus is nobly *minded;* and I fain
Would live to thank him. *Philips.*

I desire to *mind* those persons of St. Austin. *Burnet.*

They are the same beams that shine and enlighten, and are apt to scorch too; and it is impossible for a man engaged in any wicked way, to have a clear understanding of it, and a quiet *mind* in it altogether. *South.*

Suppose that after eight years peace he hath a *mind* to infringe any of his treaties, or invade a neighbouring state, what opposition can we make? *Addison.*

As the strong eagle in the silent wood,
Mindless of warlike rage, and hostile care,
Plays round the rocky cliff, or crystal flood. *Prior.*

He is daily called upon by the word, the ministers, and inward suggestions of the Holy Spirit, to attend to those prospects, and *mind* the things that belong to his peace. *Rogers.*

They will put him in *mind* of his own waking thoughts, ere these dreams had as yet made their impressions on his fancy. *Atterbury's Sermons.*

The gods permitting traitors to succeed,
Become not parties in an impious deed;
And, by the tyrant's murder, we may find,
That Cato and the gods were of a *mind*.
Granville.

A wholesome law time out of *mind*,
Had been confirmed by fate's decree. *Swift.*

Whether this last sentiment be right or wrong, I am not accountable; it is an original component feature of my *mind*. *Burns.*

Streams never flow in vain, where streams abound;
How laughs the land with various plenty crowned!
But time, that should enrich the nobler *mind*,
Neglected, leaves a dreary waste behind. *Cowper.*

Come, then, Philander! for thy lofty *mind*
Looks down from far on all that charms the great.
Beattie.

MIN'DANAO. See MAGINDANAO.

MINDEN, a government of Prussia, comprising the north-east part of what has been, since 1815, the province of Westphalia, and made up of the old principalities of Minden, Paderborn, Rittberg, and Corvey, the bailiwick of Reckeberg, and the lordship of Rheda. Its area is about 2000 square miles; its population 330,000. It is divided into thirteen districts, or circles, viz. Minden town, Minden district, Rahden, Bunde, Herford, Bielefeld, Halle, Wiedenbruck, Paderborn, Buren, Warburg, Hoxter, and Brakel. The soil is unequal, but the greatest part is fertile in corn, hemp, and flax. The manufactures are linen and thread. The pasturage is good, and the cattle numerous. The principal minerals are iron, lead, and salt. The chief river the Weser.

MINDEN, a town of Prussia, and the capital of the above government, stands in a pleasant situation, partly on eminences, on the bank of the Weser. While the see of a bishop, it formed a petty republic under his protection, and is a very old town. Over the Weser is a bridge 600 feet in length, and an object of curiosity to architects, for the correct and excellent form of its arches. It has three Lutheran, one Calvinist, and two Catholic churches; a gymnasium, orphan-house, and four hospitals. It has also a Lutheran convent; but the Catholic convent and ancient episcopal chapter, are suppressed. Here are manufactures of woollen, linen, leather, &c. Brewing is also a main pursuit; and the river affords the means of exporting corn and timber. In the vicinity is a number of saw-mills; and the Porta Westphalica, an opening in the neighbouring mountains, through which the Weser passes, is considered an object of curiosity. In 1757 Minden was taken by the French, and retaken the following year by the Hanoverians. In 1759 the French entered once more; but a memorable action, highly honorable to the British troops, being fought in the neighbourhood on the 1st of August, they were obliged to quit it immediately. It was occupied in 1806 by the French, and finally ceded to Prussia in 1814. Inhabitants 6800. Thirty-four miles west from Hanover.

MINDEN, a post town of Montgomery, county of New York, on the south side of the Mohawk; sixty-two W. N. W. Albany, west 448.

MINDORO. See PHILIPPINE ISLANDS.

MINE, *pron poss*. Sax. myn; Teut. ... Fr. *mien;* Lat. *meus*. Of or belonging to me. It was the ancient practice to use my before a consonant, and mine before a vowel, which euphony still requires. Mine is still used also when the substantive precedes: as, this cat is mine.

Jhesus answeride to hem, and seide, *myn* doctrine is not *myn*, but his that sente me. *Wiclif. Jon.* 7.

A friend of *mine* is come to me, and I have nothing to set before him. *Luke.*

While fortune unfaithfull favoured me with light godes, that sorrowful houre, that is to saie, the deth, had almoste drent *myne* hedde; but now for fortune cloudie hath chaunged her decevable chere to mewarde, *myne* unpitous life draweth along ungreable dwellynges. *Calvile.*

Thou art a soul in bliss, but I am bound
Upon a wheel of fire; that *mine* own tears
Do scald like molten lead.
Shakspeare. King Lear.

When a wise man gives thee better counsel, give me *mine* again. *Id.*

That palm is *mine*. *Dryden.*

My son! my son! may kinder stars
Upon thy fortune shine;
And may those pleasures gild thy reign,
That ne'er wad blink on *mine!* *Burns.*

MINE, *n. s. v. n.* & *v. a.*, MI'NER, *n. s.* MIN'ERAL, *n. s.* & *adj.* MIN'ERALIST, MINERAL'OGIST, MINERAL'OGY. Belg. *myn;* Teut. Dan. and Fr. *mine;* Swed. and Span. *mina;* Wel. *mum;* Fr. *mineral;* Lat. *mineralia*. A mine is a place or cavern whence minerals are dug; hence a cavern or hollow place dug under a fortification: to mine is to dig or form mines or burrows; to sap; ruin by mining; hence to destroy by degrees or secretly: a miner is one who digs in or forms mines: a mineral is a fossile substance dug from mines; an inorganic body of the mass of the earth: as an adjective, consisting of fossile substances; a mineralist, is a person working or skilled in minerals: mineralogy, is the science or doctrine of these bodies, and particularly of their classification, see below: a mineralogist one who treats of, or is skilled in this science.

Surely there is a *mine* for the silver.
Job xxviii. 1. *Marg.*

By what eclipse shall that sun be defaced?
What *mine* hath erst thrown down so fair a tower?
What sacrilege hath such a saint disgraced?
Sidney.

Build up the walls of Jerusalem, which you have broken down, and fill up the *mines* that you have digged. *Whitgift.*

It will but skin and film the ulcerous place,
While rank corruption, *mining* all within,
Infects unseen. *Shakspeare. Hamlet.*

She did confess, she had
For you a mortal *mineral;* which, being took,
Should by the minute feed on life, and lingering
By inches waste you. *Id. Cymbeline.*

The *minerals* of the kingdom, of lead, iron, copper, and tin, are of great value. *Bacon.*

They *mined* the walls, laid the powder, and rammed the mouth; but the citizens made a countermine.
Hayward.

The ranging stork in stately beeches dwells;
The climbing goats on hills securely feed;
The *mining* coneys shroud in rocky cells. *Wotton.*

Part, hidden veins digged up, nor hath this earth
Entrails unlike, of *mineral* and stone. *Milton.*

Others to a city strong
Lay siege, encamped; by battery, scale, and *mine*,
Assaulting. *Id.*

The covetous man is a downright servant, a draught horse without bells or feathers, a man condemned to work in *mines*, which is the lowest and hardest condition of servitude. *Cowley.*

Though streighter bounds your fortune did confine,
In your large heart was found a wealthy *mine*. *Waller.*

A workman, to avoid idleness, worked in a groove or *mine*-pit thereabouts, which was little esteemed. *Boyle.*

A *mine*-digger may meet with a gem or a *mineral*, which he knows not what to make of till he shows it a jeweller, or a *mineralist*. *Id.*

The metals and *minerals* which are lodged in the perpendicular intervals do still grow, to speak in the *mineralist's* phrase, or receive additional increase. *Woodward.*

By experience upon bodies in any *mine*, a man may conjecture at the metallick or *mineral* ingredients of any mass found there. *Id.*

Of this various matter the terrestrial globe consists from its surface to the greatest depth we ever dig or *mine*. *Id. Natural History.*

By me king's palaces are pushed to ground,
And *miners* crushed beneath their *mines* are found. *Dryden.*

As the bombardeer levels his mischief at cities, the *miner* busies himself in ruining private houses. *Tatler.*

A man whose great qualities want the ornament of superficial attractions, is like a naked mountain with *mines* of gold, which will be frequented only till the treasure is exhausted. *Rambler.*

Can gold calm passion, or make reason shine?
Can we dig peace, or wisdom, from the *mine*?
Wisdom to gold prefer; for 'tis much less,
To make our fortune, than our happiness. *Young.*

Mine, in the military art, a subterraneous passage, dug under the wall or rampart of a fortification intended to be blown up by gunpowder. It is commonly about four feet square; at the end of this is the chamber of the mine, which is a cavity of about five feet in width and in length, and about six feet in height, and here the gunpowder is stowed. The saucisse of the mine is the train, for which there is always a little aperture left. Two ounces of powder are capable of raising two cubic feet of earth; consequently 200 oz., or 12 lbs. 8 oz., will raise 200 cubic feet, which is only sixteen feet short of a cubic toise, because 200 oz. together have proportionably a greater force than two ounces, as being a united force. All the turnings a miner uses to carry on his mines, and through which he conducts the saucisse, should be well filled with earth and dung; and the masonry in proportion to the earth to be blown up, as three to two. The entrance of the chamber of the mine ought to be firmly shut with thick planks, in the form of St. Andrew's cross, so that the enclosure be secure, and the void spaces shut up with dung or tempered earth. If a gallery be made below, or on the side of the chamber, it must absolutely be filled up with the strongest masonry, half as long again as the height of the earth; for this gallery will not only burst, but likewise obstruct the effect of the mine. The powder should always be kept in sacks, which are opened when the mine is charged, and some of the powder strewed about; the greater the quantity of earth to be raised is, the greater is the effect of the mine, supposing it to have the due proportion of powder. The branches which are carried into the solidity of walls do not exceed three feet in depth, and two feet six inches in width nearly; this sort of mine is fit to blow up the strongest walls. The weight of a cubic foot of powder should be 80 lbs.; one foot one inch cube will weigh 100 lbs.; and one foot two inches and eleven-twelfths, 150 lbs.; and 200 lbs. of powder will be one foot five inches cube; however, there is a diversity in this, according to the quantity of saltpetre in the gunpowder. If, when the mines are made, water be found at the bottom of the chamber, dry planks are laid, on which the powder is placed either in sacks or barrels of 100 lbs. each. The saucisse must have a clear passage to the powder, and be laid in an auget or wooden trough, through all the branches. When the powder is placed in the chamber, the planks are laid to cover it, and others again across these; then one is placed over the top of the chamber, which is shaped for that purpose; between that and those which cover the powder props are placed, which shore it up; some inclining towards the outside, others to the inside of the wall, all the void spaces being filled with earth, dung, bricks, and rough stones. Afterwards planks are placed at the entrance of the chamber, with one across the top, whereon they buttress three strong props, whose other ends are likewise propped against another plank situated on the side of the earth in the branch; which props being well fixed between the planks, with wedges, the branch should then be filled up to its entrance with the forementioned materials. The saucisses which pass through the side branches must be exactly the same length with that in the middle, to which they join; the part which reaches beyond the entrance of the mine is that which conveys the fire to the other three; the saucisses, being of equal length, will spring together. See Fortification.

The force of a mine is always towards the weakest side; so that the disposition of the chamber of a mine does not at all contribute to determine this effect. The quantity of powder must be greater or less in proportion to the greater or less weight of the bodies to be raised, and to their greater or less cohesion; so that we must allow for each cubic fathom of loose earth 9 lbs. or 10 lbs. Of firm earth and strong sand, 11 lbs. or 12 lbs.; of flat clayey earth 15 lbs. or 16 lbs.; of new masonry, not strongly bound, 15 lbs. or 20 lbs.; and of old masonry, well bound, 25 lbs. or 30 lbs. The aperture, or entonnoir of a mine, if rightly charged, is a cone, the diameter of whose base is double the height taken from the centre of the mine. When the mine has been overcharged, its entonnoir is nearly cylindrical, the diameter of the upper extreme not much exceeding that of the chamber. Besides the shock of the powder against the bodies

it takes up, it likewise crushes all the earth that borders upon it, both underneath and sidewise. To charge a mine, so as to have the most advantageous effect, the weight of the matter to be carried must be known; that is, the solidity of a right cone, whose base is double the height of the earth over the centre of the mine; thus, having found the solidity of the cone in cubic fathoms, multiply the number of fathoms by the number of pounds of powder necessary for raising the matter it contains; and, if the cone contains matters of different weights, take a mean weight between them all, always having a regard to their degree of cohesion. As to the disposition of mines, there is but one general rule, viz. that the side towards which one would determine the effect be the weakest; but this varies according to circumstances.

It has been found by experiments that the figure produced by the explosion is a paraboloid, and that the centre of the powder, or charge, occupies the focus. The place where the powder is lodged is called the chamber of the mine, or fourneau. The passage leading to the powder is called the gallery. The line drawn from the centre of the chamber, perpendicular to the nearest surface of the ground, is called the line of least resistance. The pit, or hole, made by springing the mine, is called the excavation.

The fire is communicated to the mine by a pipe, or hose, made of coarse cloth, whose diameter is about one inch and a half, called a saucisson (for the filling of which near half a pound of powder is allowed to every foot), extending from the chamber to the entrance of the gallery, to the end of which is fixed a match, that the miner who sets fire to it may have time to retire before it reaches the chamber.

To prevent the powder from contracting any dampness, the saucisson is laid in a small trough, called an auget, made of boards, three inches and a half broad, joined together lengthwise, with straw in it, and round the saucisson, with a wooden cover nailed upon it.

Some authors call the end of the saucisson that comes within the work, and which is to be set fire to, the foyer, or focus; but, by most people, this is generally understood to be the centre of the chamber, though a different view is taken of the matter in Muller's Treatise.

MINES.

MINES. To carry on all the processes of the mine requires the combination of very considerable skill in several difficult branches of engineering. Most countries in which metallic veins are found, have the strata under the upper soil, consisting of rock of various degrees of hardness, it is therefore an essential part of the miner's art, and what indeed particularly distinguishes him from a common laborer, to be able to break ground of this sort under all the disadvantages of being cramped for room, exposed to constant streams of water, and not unfrequently to unwholesome air.

In Cornwall the workmen generally divide the ground, or rock, into two general classes, one of which they call working ground, and the other is distinguished by the name of shooting ground. The first class includes all such kinds of rock as may be separated or broken by the use only of the pick and wedge, which latter is technically called a gad.

The latter denomination is applied to all rock that is so hard as to require the use of gunpowder, which is bored by tools of steel, and loosened and detached by the explosion of the charges rammed into the holes.

The tools used by the miners of Cornwall and Devon are simple, and in their hands very effective; the form of the principal ones is delineated in MINING, plate I.

The pick, fig. 2, is usually of the shape shown in the drawing, but it is varied a little for some purposes, or for different kinds of rock; the one side is used as a hammer, and is called the poll, it serves to drive the gads, or to detach and loosen projecting parts; the point is steel, carefully tempered, and drawn under the hammer to its proper form, in which considerable nicety is required, as one kind of point will not do for all kinds of ground. The weights of picks are likewise various, according to the situation and circumstances in which they are to be used, but are never very heavy, as experience has fully shown that a rapid succession of smart blows, which may be given by a light tool, produces more effect than a less number from a weighty instrument, which soon tires the workman.

The gads, fig. 3, are wedges of steel, which are driven into crevices of the rock, or into small openings made with the point of the pick, and, in skilful hands, they serve to loosen ground of very dense texture.

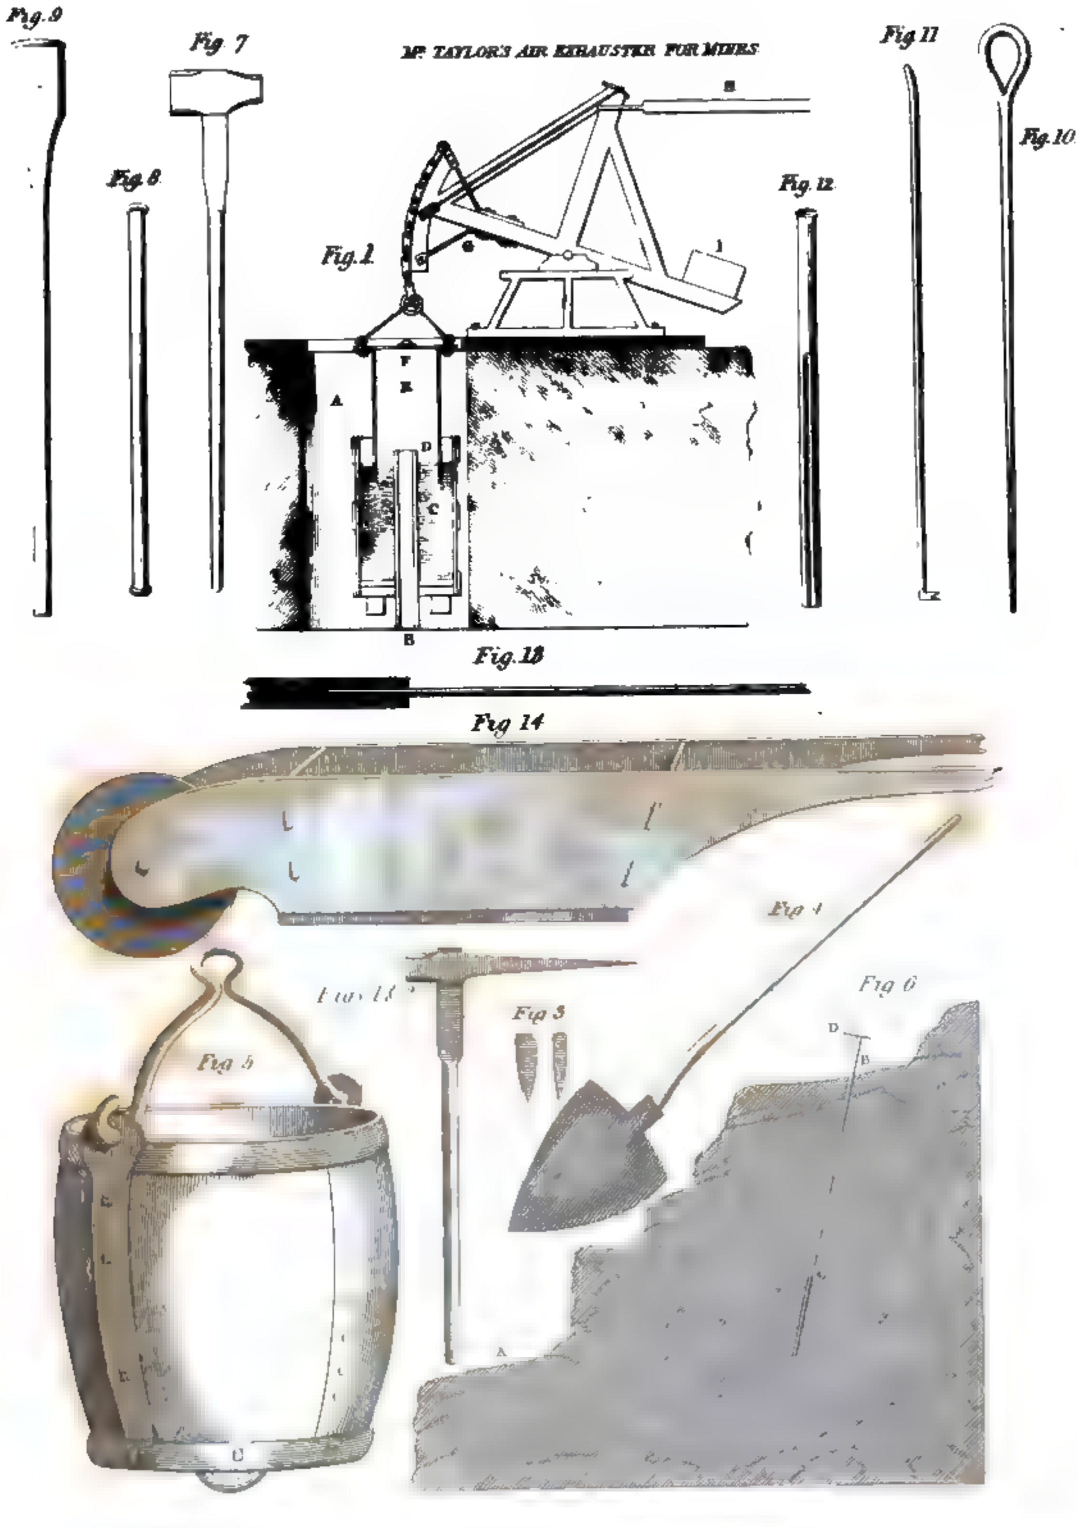
The miners' shovel, fig. 4, has a pointed form, which is necessary to make it possible to force it into or under the coarse and hard fragments of which the waste from a mine principally consists. It is furnished with a long handle somewhat bent, by which a man's power is applied in the most convenient form without stooping the body.

The tools for blasting, or, as it is technically called, shooting, consist of the

	Fig.
Sledge, or mallet,	7
Borer	8
Claying bar	9
Needle, or nail,	10
Scraper,	11
Tamping-bar,	12

Besides these tools there are required a powder-horn, rushes to be filled with powder, occasionally tin cartridges for very wet ground, and paper rubbed with gunpowder, or sometimes grease, for the snufts or fuses.

The borer, fig. 8, is a bar of iron, with a steel end, formed like a thick chisel, and is used by one man holding it in the hole and constantly turning it round, while his comrade strikes the



London Published by Thomas Tegg 73 Cheapside J. Shury Sculp

upper end with the iron sledge or mallet, fig. 7. The hole is occasionally cleaned out by the scraper, fig. 11, which is an iron rod turned up at one end; or if the ground is very wet, and the hole fills with mud, a stick beat at the extremity till it forms a kind of brush is used, and is called a swab-stick.

Holes for blasting are generally about one inch and a quarter in the bore, and of various depths from ten or twelve inches to three feet; but these, as well as the position and direction in which they are bored, and the charge of powder employed, are subject to the skill and discretion of the miner. The rules by which he is guided are to direct the effort of the explosion to a part of the rock which is most easily displaced, and to proportion the charge to the effect required, so as to shake and loosen a larger portion rather than to blow out a less quantity.

Fig. 6 serves to explain the process of blasting, and represents a section of a hole ready for firing. When the hole is bored it must be made as dry as possible; to do which it is partly filled with good tenacious clay and a round iron bar, nearly fitting the bore of the hole, but somewhat tapering, and called the claying-bar; this is driven in with great violence, which so forces the clay into all the crevices of the rock, that, when the bar is withdrawn, the hole usually remains dry. Where this plan fails, from the great flow of water all round, it becomes necessary to use tin cartridges furnished with a stem or tube through which the powder may be inflamed. A section of one of these cartridges is shown in the plate, fig. 13.

When the hole is dry, either by clay, or otherwise, the proper charge of gunpowder is introduced, and the nail, a small taper rod which ought to be made of copper, is inserted, and reaches to the bottom of the hole; the hole is then ready to receive the tamping, which is the most difficult and dangerous part of the process. It is by this that the gunpowder is confined, and the effect produced; different substances are in use for ramming into the hole for this purpose; that most usually employed is any soft kind of rock, which is free from quartz or flinty matter. Small quantities at a time are introduced into the hole, and rammed very hard by the tamping bar, which is held by one man, and struck with a sledge by another; this is continued until the hole is filled up, and the nail being then drawn out by putting a bar through the eye, and striking it upward, leaves a small perforation or vent for the rush which conveys the fire.

The danger of beating the tamping with iron tools in hard rock, and the many dreadful accidents that frequently happen in this operation, have led to the introduction of contrivances to diminish the risk; but, though some of these have been well adapted for the purpose, yet, as they occasion a little more trouble, they have not been generally adopted by the miner. The simplest and best precaution against danger is to have the nail of copper instead of iron; but, as the former is not so easily made or repaired by the smiths on a mine as the latter, they are not so well liked by the workmen.

The other mode of preventing danger in tamping is by employing substances to confine the gunpowder which require little or no force in beating them into the hole, and as dry sand will often serve the purpose if the rock is not very hard it may be sometimes used; but there are many cases in mines where it will not succeed, and therefore it is seldom attempted. A better substance to confine gunpowder in holes is good tough clay, and this will answer in many cases where sand will fail particularly in wet ground, or in holes that are inclined upwards, it will produce the proper effect in all but very hard rocks, and, if the men could be induced to use it, would undoubtedly tend to the saving many lives.

When the tamping is completely rammed in, and the nail drawn out, a small vent or touch-hole remains, which is to receive the rush to communicate the fire. Any small tube filled with gunpowder will answer for this purpose, but nothing is better or more easily prepared than those in common use. For this purpose, the green rushes which grow in wet marsh lands are chosen, and are selected as long and large as can be had. By making a slit in one side, and drawing along in it the sharp end of a piece of stick, the pith may be taken out very completely, and from the elasticity of the skin of the rush the slit closes again. To fill this tube with gunpowder, the rush is held in one hand so as to pass through a small quantity of powder retained in the palm of the hand; and by opening the slit with a small wedge, and pushing the rush along through the powder at the same time, it is made to embrace a quantity sufficient to communicate inflammation.

To fire the hole, one of these charged rushes is dropped through the vent, and is made steady by a piece of clay; a paper snuff is then fixed to the top, which is so adjusted as to burn a sufficient time to permit the man who fires it to retreat to a proper distance.

Fig. 6 represents a section of a charged hole in a rock. The portion which would be dislodged by the explosion is that part included between A and B. The charge of powder is shown by the white part, which reaches as high in the hole as C: from that point to the surface of the rock the hole is filled with tamping, excepting the small orifice which contains the rush, and which has the snuff affixed at D.

Fig. 14 is a drawing of a wheelbarrow, such as is used under ground for conveying ore and waste to the shafts: these barrows are very simple in their construction, and adapted to the narrow and low levels through which they have to pass. They are usually made all of deal, this timber being the most fitted to the purpose. The wheel has a narrow band of iron round it.

Fig. 5 is an iron bucket, or, as it is called in Cornwall, a kibble, and is used for holding the ore and waste while it is drawn up the shafts by machines, worked by horses, called whims. Kibbles are generally made of wood, having very stout staves, very strongly bound with heavy iron binds or hoops; but as those made with iron plates are to be preferred, and need not much exceed the others in weight, we are glad to be

able to exhibit a drawing of one of the latter of an approved form and construction.

A kibble, such as is used with horse-whims, holds about 300 weight of ore, and 120 kibbles will just clear a cubic fathom of rock.

Miners' work under ground is chiefly divided into sinking, driving, and stoaping.

Sinking is applied to shafts, and to other smaller perpendicular openings from one level to another, usually called winzes.

Shafts are of different dimensions according to the purposes they are designed for; the largest kind is the engine-shaft, in which are generally placed the pumps for draining the mine of water, the ladders for the men, and a part divided off and called the whim-shaft, for the kibbles to pass up and down. Plate II., Mining, will be found to represent a perspective view of a part of the interior of these shafts.

A good engine shaft measures about eight feet by twelve, though some are sunk of larger dimensions. Shafts intended only for hauling ores through, and those for air and foot-ways, may be about six feet by four.

In large shafts, a set of twelve men are usually employed; in smaller ones eight, or even six, are a sufficient complement to keep the work going. They work two or three at a time, and relieve each other every six or eight hours, keeping good the whole twenty-four without intermission. The miners are attended by laborers, or winze men, who haul up the stuff out of their way as it is broken.

Sinking is contracted for by the fathom in depth, and the price therefore varies according to the dimensions of the shaft, as well as according to the hardness of the ground, and the circumstances relating to water, air, &c. A medium price is about £20 a fathom for shafts at some depth from the surface, but some have cost £80, and others are executed as low as £5.

Driving is the term applied to the execution of horizontal passages, which are called adits when used for the conveyance of water near the surface, and levels when made for opening the lode or vein, and forming communications from one shaft to another under ground. Levels ought to be seven feet in height, and two feet and a half wide; by constructing them as high as this, room is given to admit contrivances for ventilation, so that they may be continued to considerable lengths without inconvenience. More than two miners cannot work at one time on the end of a level, and the set of men therefore employed may consist of six, relieving every eight hours, or of four relieving twice in the twenty-four hours, or two men only, who may work as long as circumstances will permit. Driving is paid for by the fathom in length, the height and width being limited; a great variation of prices takes place according as the rock is hard or soft, as work of this sort is done from 10s. a fathom to £30, but about £5 a fathom is the most usual sum paid for this kind of work. These prices here, as well as in sinking shafts, include every expense, as the men pay for their tools, candles, and gunpowder, and likewise are charged with the wheeling the stuff, and hauling it to the surface.

Stoaping is that kind of work which is not included in sinking or driving, but more generally means the breaking away the ground between the levels on the course of the lode or vein, to get the ore. When the men work over head, it is called stoaping the backs, and when the work is carried downwards it is denominated stoaping the bottoms. As both these operations usually take place where ore is obtained, the mode of payment is quite different from that in sinking or driving, and is here called tribute-work, while the other is called tutwork. Tribute means payment by a proportion of the produce, so that the men agree to undertake a particular piece of ground for a certain part of the value of the ore they may procure, when completely merchantable and fit for sale, every operation and process to make it so being conducted at their expense. This mode of contracting is of great advantage to the owners of the mine, as the men have a constant interest concurring with that of their employers, in discovering and procuring the greatest possible quantities of ore, and of returning it in the best and cheapest manner. The proportion paid to the miner, varies of course exceedingly, as many things must be taken into account in estimating a fair tribute for any particular part of a mine, but the contracts are made at so much out of every pound's worth sold, and this fluctuates often in different parts of the same mine from three-pence to fourteen shillings. Nothing shows the necessity of a mine being in the hands of skilful and honorable managers more than the great variation in the prices of all kinds of work carried on in these extensive undertakings.

An engine-shaft is delineated in Mining, plate II.

A, A, A, A, timber-framing put in to support the ground, where, from the rock not being sufficiently hard to stand securely, this precaution becomes necessary. Where boarding is required the planks are driven perpendicularly between the transverse timber and the ground.

B, B, B, B, are dividing-pieces, or beams thrown across the shaft. They serve to support the sides of the shaft, to attach the casing-boards to, which part off the whim-shaft from the foot-way and pump, or engine-shaft (it being usual to consider a large shaft of this kind as divided into the three kinds, each bearing its particular name). And, lastly, the dividing-pieces support the ends of the bearers which carry the pumps, ladders, &c.

C, C, C, C, casing-boards which part off the whim-shaft from the other parts; they are stout planks securely spiked to the dividing-pieces, and, when the shaft is not perpendicular, the kibbles slide upon them.

D, the whim-kibble which conveys up the ore and waste, two of which are employed in a shaft, one going up while the other goes down.

E, F, ladders for the workmen, forming what is usually called the foot-way.

G, saller, a small platform at the foot of each ladder.

H, a column of pumps drawing out of a cistern K, which is supplied by a lower tier of pumps I, furnished at the top with a collar

London. Published by Thom ... side

J Shury Sculp

launder J, which delivers into the cistern, which likewise receives the stream flowing from the level at L.

M, a set off, which connects the pump rods, so that one set goes into the column I, and another is continued lower to a deeper lift of pumps.

N, N, N, N, bearers, or timber beams, which support the pumps and keep them steady in their places.

The ventilation of mines is so important a subject that we insert at length the following account of a machine invented and applied to that purpose by Mr. Taylor, late the manager of the principal copper mines in Devon; and for which he received the silver medal from the society for the Encouragement of Arts, Manufactures, and Commerce.

'Next in importance to the means employed for draining underground works from water, may be reckoned those which are intended to afford a supply of pure air, sufficient to enable the workmen to continue their operations with ease and safety to themselves, and to keep up, undiminished, the artificial light upon which they depend. It is well known, indeed, to all who are practically engaged in concerns of this kind, that men are frequently obliged to persevere in their labor, where a candle will scarcely burn, and where not only their own health materially suffers in the end, but their employers are put to considerable additional expense by the unavoidable hindrance and the waste of candles and other materials.

'The following remarks are confined to such mines as are worked upon metalliferous veins, according to the practice of this district, and that of the great seat of mining in the neighbouring county of Cornwall, from which indeed ours is borrowed. We find then that a single shaft, not communicating by levels to another, can hardly be sunk to any considerable depth, nor can a level (or, as the foreign miners call it, a gallery) be driven horizontally to any great distance, without some contrivance for procuring currents of air to make up the deficiency of oxygen, which is so rapidly consumed by respiration and combustion in situations like these, where otherwise the whole remains in nearly a stagnant condition.

'We are here unacquainted with the rapid production of those gases which occasionally in the collieries are the cause of such dreadful effects; such as hydrogen gas, or the fire-damp, carbonic acid, or the choke-damp; the inconvenience we experience takes place gradually as we recede from the openings to the atmosphere, and seems to arise solely from the causes which have been before assigned, though it is found to come on more rapidly in certain situations than in others.

'The most obvious remedy, and that which is most frequently resorted to, is the opening a communication either to some other part of the mine, or to the surface itself; and as soon as this is done, the ventilation is found to be complete, by the currents which immediately take place, often with considerable force, from the different degrees of temperature in the subterranean and upper atmospheres; and these currents may be observed to change their directions as the temperatures alternate.

'The great objection to this mode of curing the evil is the enormous expense with which it is most commonly attended. In driving a long level, or tunnel, for instance, it may happen to be at a great depth under the surface, and the intervening rock of great hardness; in such a case every shaft which must be sunk upon it for air alone, where not required (as often they might not) to draw up the waste, would cost several hundred pounds; or in sinking a shaft it may be necessary, at an expense not much less, to drive a level to it from some other for this purpose alone.

'To avoid this, recourse has been had to dividing the shaft or level into two distinct parts, communicating near the part intended to be ventilated, so that a current may be produced in opposite directions on each side the partition; and this, where room is to be spared for it, is often effectual to a certain extent. It is found, however, to have its limits at no very great distance, and the current at best is but a feeble one, from the nearly equal states of heat in the air on each side. The only scheme besides these has hitherto been to force down a volume of purer air, through a system of pipes placed for the purpose, and a variety of contrivances have been devised for effecting this; most of them are so old that they may be found described in Agricola's work, De Re Metallicâ. The most common are by bellows worked by hand; by boxes or cylinders of various forms placed on the surface with a large opening against the wind, and a smaller one communicating with the air-pipes by a cylinder and piston working in it, which when driven by a sufficient force has great power. But the cheapest and most effectual scheme for this purpose, where circumstances will admit of its being applied, is one which was adopted some time since in the tunnel of the Tavistock canal. It is by applying the fall of a stream of water for this purpose, and it has been long known that a blast of considerable strength may may be obtained in this manner, which has the advantage of being constant and self-acting. The stream, being turned down a perpendicular column of pipes, dashes in at a vessel so contrived as to let off the water one way, with an opening at another part for the air, which, being pressed into it by the falling water, may be conveyed in any direction, and will pass through air-pipes with a strong current, which will be found efficacious in ventilating mines in many instances, as it has likewise, in some cases, been sufficient for urging the intensity of fires for the purposes of the forge. It is easily procured where a sufficient fall is to be had; and the perpendicular column can be so fixed as that the water from the bottom may pass off, while the air is forced into a pipe branching from the air-vessel, and which is to be continued to the part of the mine where the supply of fresh air is required.

'It has been found, however, that the forcing into vitiated air a mixture of that which is purer, even when the best means are used, though

a measure which affords relief, is not, in bad cases, a complete remedy; and, where the operation depends on manual labor, or any means that are not unremitted in their action, it becomes quite ineffectual. The foul air, charged with the smoke of gunpowder used in blasting, and which it strongly retains, is certainly meliorated by the mixture of pure air, but is not removed. While the blast continues, some of it is driven into the other parts of the mine; but, when the influx of pure air ceases, it returns again: or if, during the influx of pure air, a fresh volume of smoke be produced by explosions, which are constantly taking place, it is not until some time afterwards that it becomes sufficiently attenuated for the workmen to resume their stations with comfort.

'A consideration of these circumstances led me to the supposition that the usual operation of ventilating engines ought to be reversed, to afford all the advantages that could be desired; that, instead of using the machines which serve as condensers, exhausters should be adopted; and thus, instead of forcing pure air into that in a vitiated state, a complete remedy could only be had by pumping out all that was impure as fast as it became so.

'Many modes of doing this suggested themselves, by the alteration of the machines commonly applied, and by producing an ascending stream of air through pipes by a furnace constructed for the purpose. The latter mode would, however, have been here expensive in fuel as well as in attendance; and the others required power to overcome the friction of pistons, and so on, or considerable accuracy in construction.

'At length the machine was erected of which the annexed is a drawing; which, while it is so simple in construction, and requires so small an expense of power, is so complete in its operation, and its parts are so little liable to be injured by wear, that nothing more can be desired where such an one is applied. This engine bears considerable resemblance to Mr. Pepys's gazometer, though this did not occur to the inventer until after it was put to work. It will readily be understood by an inspection of the engraving, plate III., where the shaft of the mine is represented at A; and it may here be observed that the machine will be as well placed at the bottom of the shaft as at the top, and, in either case, it is proper to fix it upon a floor, which may prevent the return of the foul air into the mine, after being discharged from the exhauster: this floor may be furnished with a trap door, to be opened occasionally for the passage of buckets through it.

'B, the air-pipe from the mine passing through the bottom of the fixed vessel or cylinder C, which is formed of timber, and bound with iron hoops; this is filled with water nearly to the top of the pipe B, on which is fixed a valve opening upwards at D.

'E, the air or exhausting-cylinder made of cast-iron, open at the bottom and suspended over the air-pipe, immersed some way in the water. It is furnished with a wooden top, in which is an opening fitted with a valve likewise opening upwards at F.

'The exhausting-cylinder has its motion up and down given to it by the bob G, connected to any engine by the horizontal rod H, and the weight of the cylinder is balanced, if necessary, by the counterpoise I.

'The action is obvious.—When the exhausting-cylinder is raised, a vacuum would be produced, or rather the water would likewise be raised in it, were it not for the stream of air from the mine rushing through the pipe and valve D. As soon as the cylinder begins to descend, this valve closes, and prevents the return of the air which is discharged through the valve F.

'The quantity of air exhausted is calculated of course from the area of the bore of the cylinder, and the length of the stroke.

'The dimensions which have been found sufficent for large works are as follow:—

'The bore of the exhausting-cylinder two feet.

'The length six feet, so as to afford a stroke of four feet.

'The pipes which conduct the air to such an engine ought not to be less than six-inch bore.

'The best rate of working is from two to three strokes a minute; but, if required to go much faster, it will be proper to adapt a capacious air-vessel to the pipes near the machine, which will equalise the current pressing through them.

'Such an engine discharges more than 200 gallons of air in a minute; and I have found that a stream of water supplied by an inch and a half bore falling twelve feet is sufficient to keep it regularly working.

'A small engine to pump out two gallons at a stroke, which would be sufficient in many cases, could be worked by a power equal to raising a very few pounds weight, as the whole machine may be put into complete equilibrium before it begins to work, and there is hardly any other friction to overcome but that of the air passing through the pipes.

'The end of the tunnel of the Tavistock Canal, which it was my object to ventilate, was driven into the hill at a distance of nearly 300 yards from any opening to the surface; and being at a depth of 120 yards, and all in hard schistus rock, air-shafts would have been attended with an enormous expense; so that, the tunnel being a long one, it was most desirable to sink as few as possible, and, of course, at considerable distances from each other. Thus a ventilating machine was required which should act with sufficient force through a length of nearly half a mile; and, on the side of the hill where it first became necessary to apply it, no larger stream of water to give it motion could be relied on than such a one as is mentioned after the description of the engine, and even that flowed at a distance from the shaft where the engine was to be fixed, which made a considerable length of connexion-rods necessary.

'Within a very short time after the engine began to work, the superiority of its action over those formerly employed was abundantly evident. The whole extent of the tunnel, which had been uninterruptedly clouded with smoke for some months before, and which the air that was forced

in never could drive out, now became speedily so clear that the day-light and even objects at its mouth were distinctly seen from its furthest end. After blowing up the rock, the miners could instantly return to the place where they were employed, unimpeded by the smoke, of which no appearance would remain under-ground in a very few minutes, while it might be seen to be discharged in gusts, from the valve at the top of the shaft. The constant current into the pipe at the same time effectually prevented the accumulation of air unfit for respiration. The influx of air, from the level into the mouth of the pipe, rushes with such force as instantly to extinguish the flame of a large candle; and any substance applied, so as to stop the orifice, is held tight by the outward pressure.

'It is now more than two years since the machine was erected, and it has been uninterruptedly at work ever since, and without repair. The length of the tunnel has been nearly doubled, and the pipes, of course, in the same proportion, and no want of ventilation is yet perceptible.

'Two similar engines have been since constructed for other parts of the same tunnel, and have in every respect answered the purpose for which they were designed.

'The original one is worked by the small stream of water before-mentioned, by means of a light overshot-wheel twelve feet in diameter, and about six inches in breast. The two others are attached to the great overshot-wheel which pumps the water from the shafts which are sinking upon the line; and, as their friction is comparatively nothing, this may be done in any case, with so little waste of power for this purpose as not to be an object of consideration, even if the power be derived from more expensive means.

'The size of the exhauster may always be proportioned to the demand for air; and, by a due consideration of this circumstance, this engine may be effectually adapted not only to mines and collieries, but also to manufactories, workhouses, hospitals, prisons, ships, and so on.

'Thus, if it were required to ventilate a shaft of a mine, or a single level, which is most frequently the case, where three men are at work at one time, and we allow that those three men vitiate each twenty-seven cubic inches and a half of air per minute (as determined by the experiments of Messrs. Allen and Pepys), and allowing further that their candles vitiate as much as the men, there will be six times twenty-seven and a half cubic inches of air to be drawn out in a minute, equal to 165.

'Now a cylinder five inches in diameter, working with a stroke at nine inches, will effect this by one stroke in a minute; though it would certainly be advisable to make it larger.

'Not being practically acquainted with collieries, or mines that suffer from peculiar gases that are produced in them, I cannot state, from actual experiment, what effect this machine might have in relieving them; but it must appear evident, to every person at all acquainted with the first principles of pneumatics, that it must do all that can be wished, as it is obvious that such a machine must in a given time pump out the whole volume of air contained in a given space, and thus change an impure atmosphere for a better one. And in constructing the machine it is only necessary to estimate the volume of gas produced in a certain time, or the capacity of the whole space to be ventilated. It is easy to judge how much more this must do for such cases as these, than such schemes as have lately been proposed of exciting jets of water, or slaking lime, both of which projects, likewise, must fail when applied; as one of them has when applied to the case of hydrogen gas. But with such a machine as this, if the dreadful effects of explosions of this air are to be counteracted, it may be done by one of sufficient size to draw off the air as fast as it is generated; and by carrying the pipes into the elevated parts of the mine, where from its lightness it would collect. If, on the other hand, it is desired to free any subterraneous work from the carbonic acid gas, it may as certainly be done by suffering the pipe to terminate in the lower parts, where this air would be directed by its gravity.

'In workhouses, hospitals, manufactories, &c., it is always easy to calculate the quantity of air contained in any room, or number of rooms, and easy to estimate how often it is desirable to change this in a certain number of hours, and to adjust the size and velocity of the engine accordingly. Where this change of foul air for pure is to take place in the night, means for working the machine may be provided by pumping up a quantity of water into a reservoir of sufficient height to admit of its flowing out during the night in a small stream, with sufficient fall, so as to give motion to the engine; or by winding up a weight of sufficient size, or by many other means which are easily devised.

'If, for instance, a room in which fifty persons slept was eighty feet long, twenty wide, and ten high, it would contain 16,000 cubic feet of air, and, if this was to be removed twice in eight hours, it would require a cylinder of thirty inches diameter, working with a four-feet stroke four times in a minute, to do it; or nearly that. Such a cylinder could be worked by the descent of ten gallons of water ten feet in a minute; or, for the whole time, by eighty hogsheads falling the same height.

'But this is a vast deal more than could be required, as the fifty people would in eight hours vitiate only 3000 gallons of air, which could be removed by 150 strokes of a cylinder, twelve inches diameter, with a four feet stroke, which would not require an expenditure of more than 1500 gallons of water properly applied, or about twenty-eight hogsheads.'

Mr. Price, in his Treatise on the Cornish mines, observes, 'that the comparative smallness of the largest fissures to the bulk of the whole earth is really wonderful. In the finest pottery we can make, by a microscopic view, we may discover numerous cracks and fissures, so small as to be impenetrable by any fluid, and impervious to the naked eye;' as, by the laws of nature originally imposed by the Creator, it happens that matter cannot contract itself into solid large masses, without leaving fissures between them, and yet the very fissures are as necessary and

useful as the strata through which they pass. They are the drains that carry off the redundant moisture from the earth; which, but for them, would be too full of fens and bogs for animals to live, or plants to thrive on. In these fissures, the several ingredients which form lodes, by the continual passing of waters, and the menstrua of metals, are brought out of the adjacent strata, collected and conveniently lodged in a narrow channel, much to the advantage of those who search for them; for if metals and minerals were more dispersed, and scattered thinly in the body of the strata, the trouble of finding and getting at them would be endless, and the expense of procuring them exceed the value of the acquisition. The insides of the fissures are commonly coated over with a hard, crystalline, earthy substance or rind, which very often, in the breaking of hard ore, comes off along with it, and is commonly called the capels or walls of the lode: but Mr. Price is of opinion that the proper walls of the lode are the sides of the fissure itself, and not the coat, which is the natural plaster upon those walls, furnished perhaps by the contents of the fissures, or from oozings of the surrounding strata. The breadth of a lode is known by the distance betwixt the two incrusted sides of the stones of ore; and, if a lode yields any kind of ore, it is a better sign that the walls be regular and smooth, or at least that one of them be so, than otherwise; but few of these fissures have regular walls until they have been sunk down some fathoms. Thus the inner part of the figure, in which the ore lies, is all the way bounded by two walls of stone, which are generally parallel to one another, and include the breadth of the vein or lode. Whatever angle of inclination some fissures make in the solid strata, at their beginning, they generally continue to do the same all along. Some are small at their upper part, and wide underneath, and vice versâ. Their breadth, as well as depth, varies much; for, though a fissure may be many fathoms wide in one place, yet a little further east or west it may not be one inch wide. This excessive variation happens generally in very compact strata, when the vein is squeezed, as it were, through hard rocks which seem to straiten it. A true vein, however, is never entirely obliterated, but always shows a string of metallic ore, or of a veiny substance; which often serves as a leader for the miners, until it sometimes leads them to a richly impregnated part. Their length is in a great measure unlimited. The richest state for copper, according to Mr. Price, is from forty to eighty fathoms deep: for tin from twenty to sixty; and, though a great quantity of either may be raised at eighty or 100 fathoms, yet 'the quality is often too much decayed and dry for metal.' He says that the fissures or veins of the Cornish mines extend from east to west; or, more properly, one end of the fissure points west and by south, or west and by north; while the other tends east and by south, or east and by nórth. Thus they frequently pass through a considerable tract of country with few variations in their direction, unless interrupted by some intervening cause. But, besides this east and west direction, there is what the miners call the underlying or hade of the vein or lode, viz. the deflection or deviation of the fissure from its perpendicular line, as it is followed in depth like the slope of the roof of a house, or the descent of the steep side of a hill. This slope is generally to the north or south; but varies much in different veins, or sometimes even in the same vein; for it will often slope or underlie a small space in different ways, as it may be forced by hard strata on either side. Some of the fissures do not vary much from a perpendicular, while some deviate more than a fathom; that is, for every fathom they descend in perpendicular height, they deviate likewise as much to the south or north. Others differ so much from the perpendicular that they assume a position almost horizontal; whence they are also called horizontal or flat lodes, and sometimes lode plots. Another kind has an irregular position with regard to the rest; widening horizontally for a little way, and then descending perpendicularly almost like stairs, with only a small string or leader to follow after; and thus they alternately vary and yield ore in several flat horizontal fissures. This, by the Cornish tinners, is called (but in Mr. Price's opinion erroneously) a floor or squat; which, properly speaking, is a hole or chasm impregnated with metal, making no continued line of direction or regular walls. Neither does a floor of ore descend to any considerable depth; for underneath it there appears no sign of a vein, either leading directly down or any other way. This kind of vein is very rare in Britain. The fissures most common in Britain are the perpendicular and inclined, to whatever point their direction be. The perpendicular and horizontal fissures (Mr. Price says) remain little altered from their first position, when they were formed at the induration of the strata immediately after the waters left the land. The perpendicular fissures are more commonly situated in level ground, at a distance from hills, and from the sea shore; but with regard to the latter, the upper and under masses of strata differ in their solidity and properties. 'Hence (says Mr. Price) it is plain, that inclined fissures owe their deflection to some secondary cause, violence, or subsidence of the earth; for, though perpendicular fissures are seldom to be seen, yet such as are inclined at very considerable depths become more and more perpendicular, as the more central strata, by reason of the vast superincumbent weight, do not seem so likely to be driven out of their position as those which lie nearer the surface.' The fissures are often met with fractured as well as inclined; the reason of which, Mr. Price thinks, has been a subsidence of the earth, from some extraordinary cause. 'The original position, says he, must have been horizontal, or parallel to the surface of the earth: but we often find these strata very sensibly declined from the first position; nay, sometimes quite reversed, and changed into perpendicular. When we see a wall lean, we immediately conclude that the foundation has given way, according to the angles which the wall makes with the horizon; and, when we find the like declination in strata, we may conclude, by parity of reason, that there has been a like failure of what supported them,

in proportion to that declination; or that whatever made the strata to fall so much awry, must also cause every thing included in those strata to fall proportionably. Wherever the greatest subsidence is to the north the top of the lode or fissure will point to the north, and of consequence underlie to the south, and vice versâ: the slide or heave of the lode manifests the greater subsidence of the strata; but the same lode is frequently fractured and heaved in several places: all of which, by due observation, will show us they were occasioned by so many several shocks or subsidences, and that the strata were not unfooted, shaken, or brought to fall once only or twice, but several times.'

Mr. Price observes that, though the metallic veins generally run from east to west, they are frequently intersected by veins or lodes of other matters, which run from north to south. Some of these cross veins contain lead or antimony, but never tin or copper. Sometimes one of these unmetallic veins intersects the true one at right angles, sometimes obliquely; and sometimes the mixture of both is so intimate that the most expert miners are at a loss to discover the separated part of the true vein. When this last is intercepted at right angles it is moved, either north or south, a very little way, perhaps not above a fathom; in which case, having worked to a small distance in one of these directions, if they find themselves disappointed, they turn to the other hand, and seldom fail of meeting with what they expected. Sometimes they are directed in their search by the pointing of a rib or string of the true vein; but, when the interruption happens in an oblique direction, the difficulty of finding the vein again is much greater. When two metallic veins near each other run in an oblique direction, and meet together, they commonly produce a body of ore at the place where they intersect; and, if both are rich, the quantity will be considerable; but if one be poor and the other rich, then both are either enriched or impoverished by the meeting. After some time they separate again, and each will continue its former direction near to the other; but sometimes, though rarely, they continue united. It is a sign of a poor vein when it separates or diverges into strings; but, when several of them are found running into one, it is accounted a promising sign. Sometimes there are branches without the walls of the vein in the adjacent strata, which often come either obliquely or transversely into it. If these branches are impregnated with ore, or if they underlie faster than the true vein, that is, if they dip deeper into the ground, then they are said to overtake or come into the lode, and to enrich it; or, if they do not, then they are said to go off from it, and to impoverish it. But neither these nor any other marks, either of the richness or poverty of a mine, are to be entirely depended upon; for many mines, which have a very bad appearance at first, turn out extremely well afterwards; while others, which in the beginning seemed very rich, turned gradually worse; but in general, where a vein has a very bad appearance at first, it will be imprudent to be at much expense with it. Veins of metal are often so compressed betwixt hard strata that they are not an inch wide; nevertheless, if they have a string of good ore, it will generally be worth while to pursue them; and they often turn out well at last. It is an encouragement to go on, if the leaders of ore enlarge either in width or depth as they are worked; but it is a bad sign if they continue horizontal without inclining downwards; though it is not proper always to discontinue the working of a vein which has an unfavorable aspect at first. Veins of tin are worth working when only three inches wide, provided the ore be good: and copper ores, when six inches wide, will pay very well for the working. Some of the great mines, however, have very large veins, with a number of other small ones very near each other. There are also veins crossing one another sometimes met with, which are called contras, vulgarly caunters. Sometimes two veins run down into the ground in such a manner that they meet in the direction of their depths; in which case the same observations apply to them which are applicable to those that meet in a horizontal direction. Sometimes a vein suddenly disappears, by becoming narrower, or of worse quality; which by the miners is called a start or leap, and is common in the mines of Cornwall. In one day they may thus be disappointed in the working of a rich vein of tin, and have no further sign of any thing to work upon: at the fractured extremity of their vein they perceive a body of clay or other matter; and the method of recovering their vein is to drive on their work in the direction of the former part, so that their new work shall make the same angle with the clay that the other part of the vein does. Sometimes they sink a shaft down from the surface; but it is generally a matter of difficulty to recover a vein when thus lost.

The method of *discovering mines* is a matter of so much difficulty that it seems surprising how those who were totally unacquainted with the nature of metals first thought of digging them out of the earth. Lucretius says, the discovery was made by the conflagration of woods, which melted the veins of metal in the earth beneath them; and Aristotle tells us that, some shepherds in Spain having set fire to the woods, the earth was thus heated to such a degree that the silver near the surface of it melted and flowed into a mass; and that in a short time the metallic mass was discovered by the rending of the earth in the time of an earthquake. The same story is told by Strabo, who ascribes the discovery of the mines of Andalusia to this accident. The discovery of gold has been ascribed to Mercury, Cadmus, Thoas of Thrace, Piseus king of Italy, Cæacus, and other fabulous heroes; but Æschylus attributes the discovery of all the metals to Prometheus. The copper mines in Cyprus were first discovered by Cinyras, the son of Agriopas; and Hesiod ascribes the discovery of the iron mines of Crete to the Cretan Dactyli Idæi. The extraction of lead or tin from its ore, in the island of Cassiteris, according to several ancient authors, was discovered by Midacritus. Moses, however, ascribes the invention of brass and iron, or at least of the methods of working them,

to Tubal Cain, before the flood. In later times, mines have been often discovered by accident; as in sea-cliffs, among broken craggy rocks, by the washing of the tides or floods, also by irruptions and torrents of water issuing out of hills and mountains, and sometimes by the wearing of high roads. Mr. Price mentions, among other methods by which mines have been discovered, one by fiery corruscations, ignes fatui, or falling stars, and says, 'the tinners generally search with uncommon eagerness the ground over which these jack-a-lanterns have appeared.' But this mode of judging of mines has now lost all credit. Mines are now most commonly discovered by investigating the nature of such veins, ores, and stones, as seem most likely to turn to account: but there is a particular sagacity, or habit of judging from particular signs, which can be acquired only by long practice. Mines, especially those of copper, may also be discovered by the harsh and disagreeable taste of the waters which issue from them; though this only happens when the ore lies above the level of the water; for it does not seem likely that the taste of the ore could ascend, unless we were to suppose a pond or lake of water standing above it. The presence of copper in any water is easily discovered by immerging in it a bit of polished iron, which will thus instantly be turned of a copper color, by the precipitation of the metal upon it. A candle, or piece of tallow, put into water of this kind, will in a short time be tinged green. Another, and still more wonderful method of discovering mines, is said to be by the virgula divinatoria, or divining-rod; which, however incredible the stories related concerning it may be, is still relied on by some, and among others by Mr. Price. It is not known who was the inventor of this method; but Agricola supposes that it took its rise from the magicians, who pretended to discover mines by enchantment. No mention is made of it, however, before the eleventh century, since which time it has been in frequent use; and the Corpuscular Philosophy has even been called in to account for it. It is said to be performed in consequence of a certain unaccountable attraction which the metals have for rods of nut or other fruit-trees. But the account given by Price, which he had from a Mr. Cookworthy of Plymouth, who is said to have had the first information concerning this rod from one captain Ribera, a deserter from the Spanish service in queen Anne's reign, and afterwards captain-commandant in the garrison of Plymouth, is so very incredible, not to add unintelligible and unphilosophical, that we think it unnecessary to quote it; and shall therefore leave it to be investigated from Mr. Price's work, by such of our readers (if any such there be) as have faith in the obsolete and occult sciences of astrology, enchantment, and magic. Another, and very ancient mode of discovering mines, but extremely difficult and precarious, is that called shoding; that is, tracing them by loose stones, fragments, or shodes, which may have been separated and carried off to a considerable distance from the vein, and are found by chance in running waters, on the surface of the ground, or a little under. 'When the tinners,' says Mr. Price, 'meet with a loose single stone of tin ore, either in a valley, or in ploughing or hedging, though at 100 fathoms distance from the vein it came from, those who are accustomed to this work will not fail to find it out. They consider that a metallic stone must originally have appertained to some vein, from which it was severed and cast at a distance by some violent means. The deluge, they suppose, moved most of the loose earthy coat of the globe, and in many places washed it off from the upper towards the lower grounds, with such a force that most of the backs or lodes of veins which protruded themselves above the fast were hurried downwards with the mass: whence the skill in this part of their business lies much in directing their measures according to the situation of the surface.' Afterwards, however, our author complains, that this art of shoding, as he calls it, is in a great measure lost. The following account of a method of finding silver mines, by Alonzo Barba, seems to be similar to that of shoding:—'The veins of metal,' says he, 'are sometimes found by great stones above ground; and if the veins be covered they hunt them out after this manner: viz. taking in their hands a sort of mattock, which has a steel point at one end to dig with, and a blunt head at the other, wherewith to break stones, they go to the hollows of the mountains, where the current of rain water descends, or to some other part of the skirts of the mountains, and there observe what stones they meet with, breaking in pieces those that seem to have any metal in them; whereof they find many times both middling sort of stones and small ones also of metal. Then they consider the situation of that place, and whence these stones can tumble, which of necessity must be from higher ground, and follow the tract of them up the hill as long as they can find any of them,' &c. Another way, says Mr. Price, of discovering lodes, is by working drifts across the country, as we call it, that is, from north to south, and vice versâ. I tried the experiment in an adventure under my management, where I drove all open at grass about two feet in the shelf, very much like a level to convey water upon a mill-wheel; by so doing I was sure of cutting all lodes in my way; and did accordingly discover five courses, one of which has produced above 180 tons of copper-ore, but the others were never wrought upon. This method of discovering lodes is equally cheap and certain; for 100 fathoms in shallow ground may be driven at 50s. expense.' In that kind of ground called by our author feasible, and which he explains by the phrase tender-standing, he tells us that 'a very effectual, proving, and consequential way is, by driving an adit from the lowest ground, either north or south, whereby there is a certainty to cut all lodes at twenty, thirty, or forty fathoms deep, if the level admits of it. In driving adits or levels across, north or south, to unwater mines already found, there are many fresh veins discovered, which frequently prove better than those they were driving to.'

After the mine is found, the next thing to be considered is, whether it may be dug to advantage. To determine this we are duly to

weigh the nature of the place, and its situation, as to wood, water, carriage, healthiness, and the like; and compare the result with the richness of the ore, the charge of digging, stamping, washing, and smelting. The form and situation of the spot should be well considered. A mine must either happen, 1. In a mountain; 2. In a hill; 3. In a valley; or, 4. In a flat. But mountains and hills are dug with much greater ease and convenience, chiefly because the drains and burrows, that is, the adits or avenues, may be here readily cut, both to drain the water, and to form gangways for bringing out the lead, &c. In all the four cases we are to look out for the veins which the rains or other accidental thing may have laid bare; and, if such a vein be found, it may often be proper to open the mine at that place, especially if the vein prove tolerably large and rich; otherwise the most commodious place for situation is to be chosen for the purpose, viz. neither on a flat, nor on the tops of mountains, but on the sides. The best situation for a mine is a mountainous, woody, wholesome spot, of a safe and easy ascent, and near a navigable river. The places abounding with mines are generally healthy, as standing high, and every where exposed to the air; yet some places where mines are found prove poisonous, and can upon no account be dug, though ever so rich: the way of examining a suspected place of this kind is to make experiments upon brutes, by exposing them to the effluvia, to discover their effects. Devonshire and Cornwall, where there are many mines of copper and tin, are very mountainous; which gives an opportunity to make adits or subterraneous drains to some valley at a distance, by which to carry off the water from the mine, which otherwise would prevent them from getting the ore. These adits are sometimes carried a mile or two, and dug at an experse of from £2000 to £4000, especially where the ground is rocky; and yet they find this cheaper than to draw up the water out of the mine quite to the top, when the water runs in plenty and the mine is deep. Sometimes, indeed, they cannot find a level near enough, to which an adit may be carried from the very bottom of the mine; yet they find it worth while to make an adit at half the height to which the water is to be raised, thereby saving half the expense. The late Mr. Costar, considering that sometimes from small streams, and sometimes from little springs or collections of rain water, one might have a good deal of water above ground, though not a sufficient quantity to turn an overshot-wheel, thought that, if a sufficient fall might be had, this collection of water might be made useful in raising the water in a mine to the adit, where it may be carried off. But now the most general method of draining mines is by the steam engine. See Steam Engine, Metallurgy, and Mineralogy.

MINEHEAD, an ancient seaport and market-town of Somersetshire, with a harbour in the Bristol Channel, near Dunster Castle, formerly much frequented by passengers to and from Ireland. It was incorporated by queen Elizabeth, with great privileges, on condition of keeping the quay in repair; but its trade falling off, the quay was neglected, and the privileges were lost. A statute was obtained in the reign of William III. for recovering the port, and keeping it in repair; and the quay was rebuilt. In pursuance of another act, a new head was built to the quay, and the beach cleared. It was formerly governed by a portreve, and now by two constables chosen annually at a court-leet, held by the lord of the manor. Its chief trade is with Ireland, whence about forty vessels used to come hither in a year with wool. The market is on Wednesday, and fair on Whitsun-Wednesday. Minehead is thirty-one miles north of Exeter, and 163 west by south of London.

MINERAL WATERS.

Mineral Waters, or Mineral Springs. All waters naturally impregnated with any heterogeneous matter which they have dissolved within the earth may be called mineral waters, in the most extensive meaning of that name; which might therefore comprehend almost all those that flow within or upon the earth; for almost all these contain some earth or selenites. But waters containing only earth or selenites are not generally called mineral, but hard or crude waters. These, when chemically analysed, show no marks of an acid or alkali, nor of any volatile, sulphureous, or metallic matters. Waters which contain calcareous earth change the color of syrup of violets to a green; and those that contain selenites, being mixed with a solution of mercury in nitrous acid, form a turbith mineral; and, when a fixed alkali is added, they are rendered turbid, and a white sediment is precipitated. These waters do not dissolve soap well. Any water which produces these effects is a hard, earthy, or selenitic water. The waters impregnated with gases are also hard. Although the waters of the sea and saline springs be not generally enumerated amongst mineral waters, they might nevertheless be justly considered as such; for, besides earthy and selenitic matters, they also contain a large quantity of mineral salts. But mineral waters, properly so called, are those in which gas, or sulphureous, saline, or metallic substances, are discovered by chemical trials. As many of these are employed successively in medicine, they are also called medicinal waters. Mineral waters receive their peculiar principles by passing through earths containing salts, or other mineral substances, in

a state of decomposition. Some of these are valuable for the quantity of useful salts which they contain, particularly of common salt, see SALT, and others for their medicinal qualities. 'All waters,' says Dr. Thomson, 'which are distinguished from common water by a peculiar smell, taste, color, &c., and which, in consequence of these properties, cannot be applied to the purposes of domestic economy, have been called mineral waters. These occur in different parts of the earth, constituting wells, springs, or fountains; sometimes of the temperature of the soil through which they pass, sometimes warm, and in some cases even at the boiling temperature. Mineral springs,' continues this writer, 'attracted the attention of mankind in the earliest ages, and were resorted to by those who labored under diseases, and employed as a medicine. But it was not till towards the end of the seventeenth century that any attempt was made to detect the ingredients of which these waters were composed, or to discover the substances to which they owed their properties. Mr. Boyle may be considered as the first who pointed out the method of examining water. He first ascertained the existence of air in it, and pointed out a number of tests, by which conjectures might be made concerning the saline bodies which the water held in solution. In 1665 Dominici Du Clos attempted to examine the mineral waters in France. He employed almost all the re-agents recommended by Boyle, and added several of his own. In 1680 Hierne published a set of experiments on the mineral waters of Sweden. Soon after various improvements were introduced by Regis, Didier, Burlet, and Homberg; and in 1726 Boulduc pointed out a method of precipitating several of the saline contents of water by alcohol. But it was not till after the discovery of carbonic acid, by Dr. Black, that any considerable progress was made in ascertaining the composition of mineral waters. That subtile acid which is so often contained, and which serves as a solvent to many of the earths, and even metallic bodies, had thwarted all the attempts of former chemists to detect the composition of these liquids. Since the discovery of this acid the analysis of mineral waters has advanced with great rapidity, in consequence, chiefly, of the admirable dissertation on the subject published by Bergman in 1778. Since that period, much has been done by Gioanetti, Black, Klaproth, Westrumb, Fourcroy, Brezé, Kirwan, and many other eminent chemists; so that, notwithstanding the difficulty of the subject, scarcely any branch of chemistry has made greater progress, or is farther advanced, than the knowledge of mineral waters.

Dr. Ure has very ably digested the latest information on this subject: we quote his chemical analysis, as below, together with his table of the principal mineral waters. To Dr. Ryan late of Kilkenny, now of London, we are indebted for the ample list of all the known mineral waters which follows. It was first published by him in the London Medical and Physical Journal; but he has favored us with his own latest corrections of the original paper.

'The topography of the place where these waters rise is the first thing to be considered,' observes Dr. Ure. 'By examining the ooze formed by them, and the earth or stones through which they are strained and filtered, some judgment may be formed of their contents. In filtering through the earth, and meandering on its surface, they take with them particles of various kinds, which their extreme attenuation renders capable of being suspended in the fluid that serves for their vehicle. Hence we shall sometimes find in these waters, siliceous, calcareous, or argillaceous earth; and at other times, though less frequently, sulphur, magnesian earth, or, from the decomposition of carbonated iron, ochre.

The following are the ingredients that may occur in mineral waters:—

1. Air is contained in by far the greater number of mineral waters: its proportion does not exceed one twenty-eighth of the bulk of the water.

2. Oxygen gas was first detected in waters by Scheele. Its quantity is usually inconsiderable; and it is incompatible with the presence of sulphuretted hydrogen gas or iron.

3. Hydrogen gas was first detected in Buxton water by Dr. Pearson. Afterwards it was discovered in Harrowgate waters by Dr. Garnet, and in those of Leamington Priors by Mr. Lambe.

4. Sulphuretted hydrogen gas constitutes the most conspicuous ingredient in those waters, which are distinguished by the name of hepatic or sulphurous.

The only acids hitherto found in waters, except in combination with a base, are the carbonic, sulphuric, and boracic.

5. Carbonic acid was first discovered in Pyrmont water by Dr. Brownrigg. It is the most common ingredient in mineral waters, 100 cubic inches of the water generally containing from six to forty cubic inches of this acid gas. According to Westrumb, 100 cubic inches of Pyrmont water contain 187 cubic inches of it, or almost double its own bulk.

6. Sulphurous acid has been observed in several of the hot mineral waters in Italy, which are in the neighbourhood of volcanoes.

7. The boracic acid has also been observed in some lakes in Italy.

The only alkali which has been observed in mineral waters, uncombined, is soda; and the only earthy bodies are silex and lime.

8. Dr. Black detected soda in the hot mineral waters of Geyser and Rykum in Iceland; but in most other cases the soda is combined with carbonic acid.

9. Silex was first discovered in waters by Bergman. It was afterwards detected in those of Geyser and Rykum by Dr. Black, and in those of Karlsbad by Klaproth. Hassenfratz observed it in the waters of Pougues, as Brezé did in those of Pu. It has been found also in many other mineral waters.

10. Lime is said to have been found uncombined in some mineral waters; but this has not been proved in a satisfactory manner.

The only salts hitherto found in mineral waters are the following:—sulphates, nitrates, muriates, carbonates and borates; and of these the carbo-

nates and muriates occur by far most commonly, and the borates and nitrates most rarely.

11. Sulphate of soda is not uncommon, especially in those mineral waters which are distinguished by the epithet saline.

12. Sulphate of ammonia is found in mineral waters near volcanoes.

13. Sulphate of lime is exceedingly common in water. Its presence seems to have been first detected by Dr. Lister in 1682.

14. Sulphate of magnesia is almost constantly an ingredient in those mineral waters which have purgative properties. It was detected in Epsom waters in 1610, and in 1696 Dr. Grew published a treatise on it.

15. Alum is sometimes found in mineral waters, but it is exceedingly rare.

16. Sulphate of iron occurs sometimes in volcanic mineral waters, and has even been observed in other places.

17. Sulphate of copper is only found in the waters which issue from copper mines.

18. Nitre has been found in some springs in Hungary, but it is exceedingly uncommon.

19. Nitrate of lime was first detected in water by Dr. Home, of Edinburgh, in 1756. It is said to occur in some springs in the sandy deserts of Arabia.

20. Nitrate of magnesia is said to have been found in some springs.

21. Muriate of potash is uncommon; but it has lately been discovered in the mineral springs of Uhleaborg in Sweden by Julin.

22. Muriate of soda is so extremely common in mineral waters that hardly a single spring has been analysed without detecting some of it.

23. Muriate of ammonia is uncommon, but it has been found in some mineral springs in Italy and Siberia.

24. Muriate of barytes is still more uncommon, but its presence in mineral waters has been announced by Bergman.

25 and 26. Muriates of lime and magnesia are common ingredients.

27. Muriate of alumina has been observed by Dr. Withering, but it is very uncommon.

28. Muriate of manganese was mentioned by Bergman as sometimes occurring in mineral waters. It has lately been detected by Lambe in the waters of Leamington Priors, but in an extremely limited proportion.

29. The presence of carbonate of potash in mineral waters has been mentioned by several chemists; if it do occur, it must be in a very small proportion.

30. Carbonate of soda is, perhaps, one of the most common ingredients of these liquids, if we except common salt and carbonate of lime.

31. Carbonate of ammonia has been discovered in waters, but it is uncommon.

32. Carbonate of lime is found in almost all waters, and is usually held in solution by an excess of acid. It appears from the different experiments of chemists, as stated by Mr. Kirwan, and especially from those of Berthollet, that water saturated with carbonic acid is capable of holding in solution 0·002 of carbonate lime. Now water saturated with carbonic acid, at the temperature of 50°, contains very nearly 0·002 of its weight of carbonic acid. Hence it follows that carbonic acid, when present in such quantity as to saturate waters, is capable of holding its own weight of carbonate of lime in solution. Thus we see 1000 parts by weight of water, when they contain two parts of carbonic acid, are capable of dissolving two parts of carbonate of lime. When the proportion of water is increased, it is capable of holding the carbonate of lime in solution, even when the proportion of carbonic acid united with it is diminished. Thus 24,000 parts of water are capable of holding two parts of carbonate of lime in solution, even when they contain only one part of carbonic acid. The greater the proportion of water, the smaller proportion of carbonic acid is necessary to keep the lime in solution; and, when the water is increased to a certain proportion, no sensible excess of carbonic acid is necessary. It ought to be remarked also, that water, however small a quantity of carbonic acid it contains, is capable of holding carbonate of lime in solution, provided the weight of the carbonic acid present exceed that of the lime. These observations apply equally to the other earthy carbonates held in solution by mineral waters.

33. Carbonate of magnesia is also very common in mineral waters, and is almost always accompanied by carbonate of lime.

34. Carbonate of alumina is said to have been found in waters, but its presence has not been properly ascertained.

35. Carbonate of iron is by no means uncommon; indeed, it forms the most remarkable ingredient in those waters which are distinguished by the epithet of chalybeate.

36. Borax exists in some lakes in Persia and Thibet, but the nature of these waters has not been ascertained.

37 and 38. The hydrosulphurets of lime and of soda have been frequently detected in those waters which are called sulphurous, or hepatic.

Mr. Westrumb says, that all sulphurous waters contain more or less hydrosulphuret of lime. To detect this he boiled the mineral water, excluding the contact of atmospheric air, to expel the sulphuretted hydrogen gas and carbonic acid. Into the water thus boiled he poured sulphuric acid, when more sulphuretted hydrogen gas was evolved, and sulphate of lime was thrown down; fuming nitric acid, which separated from it sulphur; and oxalic acid, which expelled sulphuretted hydrogen, and formed oxalate of lime. The water evaporated in open vessels let fall sulphate of lime, and gave out sulphuretted hydrogen gas. To ascertain the quantity of sulphuretted hydrogen gas and carbonic acid, Mr. Westrumb proceeded as follows:—He introduced the sulphurous water into a matrass, till it was filled to a certain point, which he marked; fitted to it a curved tube, which terminated in a long cylinder; filled this cylinder with lime water for the one experiment, and with acetate of lead, with excess of acid, for the other; luted the apparatus; and boiled the water till no more gas was expelled. When the lime water is used, carbonate of lime is precipitated in the proportion of twenty grains to every ten cubic inches of carbonic acid gas: when the solution of acetate of lead, hydrosulphuret of lead is thrown down, in

the proportion of nineteen grains to ten cubic inches of sulphuretted hydrogen gas.

Beside these substances, certain vegetable and animal matters have been occasionally observed in mineral waters. But in most cases these are rather to be considered in the light of accidental mixtures, than of real component parts of the waters in which they occur. From this synoptical view of the different ingredients contained in mineral waters, it is evident that these substances occur in two different distinct states: 1. As being suspended in them; and 2. As being dissolved in them chiefly in the form of a salt.

The investigation of mineral waters consists, 1. In the examination of them by the senses: 2. In the examination of them by re-agents: 3. In the analysis properly so called.

The examination by the *senses* consists in observing the effect of the water as to appearance, smell, and taste. The appearance of the water, the instant in which it is pumped out of the well, as well as after it has stood for some time, affords several indications, from which we are enabled to form a judgment concerning its contents. If the water be turbid at the well, the substances are suspended only, and not dissolved; but if the water be clear and transparent at the well, and some time intervenes before it becomes turbid, the contents are dissolved by means of carbonic acid. The presence of this gas is likewise indicated by small bubbles, that rise from the bottom of the well, and burst in the air while they are making their escape, though the water at the same time perhaps has not an acid taste. This is the case, according to count Razoumowski, with respect to the tepid springs in Vallais, and the cold vitriolated chalybeate springs at Astrakhan. But the most evident proof of a spring containing carbonic acid is the generation of bubbles on the water being shaken, and their bursting with more or less noise while the air is making its escape. The sediment deposited by the water in the well is likewise to be examined: if it be yellow, it indicates the presence of iron; if black, that of iron combined with sulphur; but, chalybeate waters being seldom sulphuretted, the latter occurs very rarely. As to the color of the water itself, there are few instances where this can give any indication of its contents, as there are not many substances that color it. The odor of the water serves chiefly to discover the presence of sulphuretted hydrogen in it: such waters as contain this substance have a peculiar fetid smell, somewhat resembling rotten eggs. The taste of a spring, provided it be perfectly ascertained by repeated trials, may afford some useful indications with respect to the contents. It may be made very sensible by tasting water in which the various salts that are usually found in such waters are dissolved in various proportions. There is no certain dependence, however, to be placed on this mode of investigation; for, in many springs, the taste of sulphate of soda is disguised by that of the sea salt united with it. The water too is not only to be tasted at the spring, but after it has stood for some time. This precaution must be particularly observed with respect to such waters as are impregnated with carbonic acid; for the other substances contained in them make no impression on the tongue, till the carbonic acid has made its escape; and it is for the same reason that these waters must be evaporated in part, and then tasted again. Though the specific gravity of any water contributes but very little towards determining its contents, still it may not be entirely useless to know the specific weight of the water, the situation of the spring, and the kind of sediment deposited by it.

The examination of the water by means of *re-agents* shows what they contain, but not how much of each principle. In many instances this is as much as the enquiry demands; and it is always of use to direct the proceedings in the proper analysis. It is absolutely necessary to make the experiment with water just taken up from the spring, and afterwards with such as has been exposed for some hours to the open air; and sometimes a third essay is to be made with a portion of the water that has been boiled and afterwards filtered. If the water contain but few saline particles, it must be evaporated; as even the most sensible re-agents do not in the least affect it, if the salts, the presence of which is to be discovered by them, are diluted with too great a quantity of water. Now, it may happen, that a water shall be impregnated with a considerable number of saline particles of different kinds, though some of them may be present in too small a quantity; for which reason the water must be examined a second time, after having been boiled down to three-fourths.

The substances of which the presence is discoverable by re-agents, are:—

1. Carbonic acid. When this is not combined with any base, or not with sufficient to neutralise it, the addition of lime water will throw down a precipitate soluble with effervescence in muriatic acid. The infusion of litmus is reddened by it: but the red color gradually disappears, and may be again restored by the addition of more of the mineral water. When boiled it loses the property of reddening the infusion of litmus. According to Pfaff, the most sensible test of this acid is acetate of lead.

2. The mineral acids, when present uncombined in water, give the infusion of litmus a permanent red, even though the water has been boiled. Bergman has shown that paper stained with litmus is reddened when dipped into water containing $\frac{1}{3321}$ of sulphuric acid.

3. Water containing sulphuretted hydrogen gas is distinguished by the following properties: It exhales the peculiar odor of sulphuretted hydrogen gas. It reddens the infusion of litmus fugaciously. It blackens paper dipped into a solution of lead, and precipitates the nitrate of silver black or brown.

4. Alkalis, and alkaline and earthy carbonates, are distinguished by the following tests:—the infusion of turmeric, or paper stained with turmeric, is rendered brown by alkalis; or reddish-brown, if the quantity be minute. This change is produced when the soda in water amounts only to $\frac{1}{1817}$ part. Paper stained with Brasil wood, or the infusion of Brasil wood, is rendered blue; but this change is produced also by the alkaline and earthy carbonates. Bergman ar-

certained that water, containing [illegible]th part of carbonate of soda, reddens paper stained with Brasil wood blue. Litmus paper reddened by vinegar is restored to its original blue color. This change is produced by the alkaline and earthy carbonates also. When these changes are fugacious, we may conclude that the alkali is ammonia.

5. Fixed alkalis exist in water that occasions a precipitate with muriate of magnesia after being boiled. Volatile alkali may be distinguished by the smell; or it may be obtained in the receiver by distilling a portion of the water gently, and then it may be distinguished by the above tests.

6. Earthy and metallic carbonates are precipitated by boiling the water containing them; except carbonate of magnesia, which is precipitated but imperfectly.

7. Iron is discovered by the following tests:—The addition of tincture of gall gives water, containing iron, a purple or black color. This test indicates the presence of a very minute portion of iron. If the tincture have no effect upon the water, after boiling, though it colors it before, the iron is in the state of a carbonate. The following observations of Westrumb on the color which iron gives to galls, as modified by other bodies, deserve attention. A violet indicates an alkaline carbonate, or earthy salt. Dark purple indicates other alkaline salts. Purplish-red indicates sulphuretted hydrogen gas. Whitish, and then black, indicates sulphate of lime. Mr. Phillips has lately ascertained that, while the iron is little oxided, the presence of lime rather facilitates the application of this test; but the lime prevents the test from acting, provided the iron be considerably oxidised. The prussian alkali occasions a blue precipitate in water containing iron. If an alkali be present, the blue precipitate does not appear unless the alkali is saturated with an acid.

8. Sulphuric acid exists in waters that form a precipitate with the following solutions: muriate, nitrate, or acetate of barytes, strontia, or lime, or nitrate or acetate of lead. Of these the most powerful by far is muriate of barytes, which is capable of detecting the presence of sulphuric acid uncombined, when it does not exceed the $\frac{1}{1000000}$th part of the water. Acetate of lead is next in point of power. The muriates are more powerful than the nitrates. The calcareous salts are least powerful. All these tests are capable of indicating a much smaller proportion of uncombined sulphuric acid than when it is combined with a base. To render muriate of barytes a certain test of sulphuric acid, the following precautions must be observed:—The muriate must be diluted; the alkalis or alkaline carbonates, if the water contain any, must be previously saturated with muriatic acid; the precipitate must be insoluble in muriatic acid; if boracic acid be suspected, muriate of strontia must be tried, which is not precipitated by boracic acid. The hydrosulphurets precipitate barytic solutions, but their presence is easily discovered by the smell.

9. Muriatic acid is detected by nitrate of silver, which occasions a white precipitate or a cloud, in water containing an exceedingly minute portion of this acid. To render this test certain, the following precautions are necessary:—The alkalis or carbonates must be previously saturated with nitric acid. Sulphuric acid, if any be present, must be previously removed by means of nitrate of barytes. The precipitate must be insoluble in nitric acid. Pfaff says, that the mild nitrate of mercury is the most sensible test of muriatic acid; and that the precipitate is not soluble in an excess of any acid.

10. Boracic acid is detected by means of acetate of lead, with which it forms a precipitate insoluble in acetic acid. But, to render this test certain, the alkalis and earths must be previously saturated with acetic acid, and the sulphuric and muriatic acids removed by means of acetate of strontia and acetate of silver.

11. Barytes is detected by the insoluble white precipitate which it forms with diluted sulphuric acid.

12. Lime is detected by means of oxalic acid, which occasions a white precipitate in water containing a very minute proportion of this earth. To render this test decisive the following precautions are necessary:—The mineral acids, if any be present, must be previously saturated with an alkali. Barytes, if any be present, must be previously removed by means of sulphuric acid. Oxalic acid precipitates the magnesia but very slowly, whereas it precipitates lime instantly.

13. Magnesia and alumina. The presence of these earths is ascertained by the following tests: pure ammonia precipitates them both, and no other earth, provided the carbonic acid have been previously separated by a fixed alkali and boiling. Lime water precipitates only these two earths, provided the carbonic acid be previously removed, and the sulphuric acid also, by means of nitrate of barytes.

The alumina may be separated from the magnesia, after both have been precipitated together, either by boiling the precipitate in caustic potassa, which dissolves the alumina and leaves the magnesia; or the precipitate may be dissolved in muriatic acid, precipitated by an alkaline carbonate, dried in the temperature of 100°, and then exposed to the action of diluted muriatic acid, which dissolves the magnesia without touching the alumina.

14. Silex may be ascertained by evaporating a portion of water to dryness, and redissolving the precipitate in muriatic acid. The silex remains behind undissolved.

By these means we may detect the presence of the different substances commonly found in waters; but, as they are generally combined so as to form salts, it is necessary we should know what these combinations are. This is a more difficult task, which Mr. Kirwan teaches us to accomplish by the following methods:—1. To ascertain the presence of the different sulphates. The sulphates which occur in water are seven; but one of these, namely, sulphate of copper, is so uncommon, that it may be excluded altogether. The same remark applies to sulphate of ammonia. It is almost necessary to observe, that no sulphate need be looked for, unless both its acid and base have been previously detected in

the water. Sulphate of soda may be detected by the following method:—Free the water to be examined of all earthy sulphates, by evaporating it to one-half, and adding lime water as long as any precipitate appears. By these means the earths will all be precipitated except lime, and the only remaining earthy sulphate will be sulphate of lime, which will be separated by evaporating the liquid till it becomes concentrated, and then dropping into it a little alcohol, and, after filtration, adding a little oxalic acid. With the water, thus purified, mix solution of lime. If a precipitate appear, either immediately or on the addition of a little alcohol, it is a proof that sulphate of potassa or of soda is present Which of the two may be determined, by mixing some of the purified water with acetate of barytes. Sulphate of barytes precipitates. Filter and evaporate to dryness. Digest the residuum in alcohol. It will dissolve the alkaline acetate. Evaporate to dryness, and the dry salt will deliquesce if it be acetate of potassa, but effloresce if it be acetate of soda. Sulphate of lime may be detected by evaporating the water suspected to contain it to a few ounces. A precipitate appears, which, if it be sulphate of lime, is soluble in 500 parts of water; and the solution affords a precipitate with the muriate of barytes, oxalic acid, carbonate of magnesia, and alcohol. Alum may be detected by mixing carbonate of lime with the water suspected to contain it. If a precipitate appear, it indicates the presence of alum, or at least of sulphate of alumina; provided the water contains no muriate of barytes or metallic sulphates. The first of these salts is incompatible with alum: the second may be removed by the alkaline prussiates. When a precipitate is produced in water by muriate of lime, carbonate of lime, and muriate of magnesia, we may conclude that it contains alum or sulphate of alumina. Sulphate of magnesia may be detected by means of hydrosulphuret of strontia, which occasions an immediate precipitate with this salt, and with no other; provided the water be previously deprived of alum, if any be present, by means of carbonate of lime, and provided also that it contain no uncombined acid. Sulphate of iron is precipitated from water by alcohol, and then it may be easily recognised by its properties.

2. To ascertain the presence of the different muriates. The muriates found in waters amount to eight, or to nine if muriate of iron be included. The most common by far is muriate of soda. Muriate of soda and of potassa may be detected by the following method: Separate the sulphuric acid by alcohol and nitrate of barytes. Decompose the earthy nitrates and muriates by adding sulphuric acid. Expel the excess of muriatic and nitric acids by heat. Separate the sulphates thus formed by alcohol and barytes water. The water thus purified can contain nothing but alkaline nitrates and muriates. If it form a precipitate with acetate of silver, we may conclude that it contains muriate of soda or of potassa. To ascertain which, evaporate the liquid thus precipitated to dryness. Dissolve the acetate in alcohol, and again evaporate to dryness. The salt will deliquesce, if it be acetate of potassa; but effloresce if it be acetate of soda. Muriate of barytes may be detected by sulphuric acid, as it is the only barytic salt hitherto found in water. Muriate of lime may be detected by the following method.—Free the water from sulphate of lime and other sulphates by evaporating it to a few ounces, mixing it with alcohol, and adding last of all nitrate of barytes, as long as any precipitate appears. Filter the water; evaporate to dryness; treat the dry mass with alcohol; evaporate the alcohol to dryness; and dissolve the residuum in water. If this solution give a precipitate with acetate of silver and oxalic acid, it may contain muriate of lime. It must contain it in that case, if, after being treated with carbonate of lime, it give no precipitate with ammonia. If the liquid in the receiver give a precipitate with nitrate of silver, muriate of lime existed in the water. Muriate of magnesia may be detected by separating all the sulphuric acid by means of nitrate of barytes. Filter; evaporate to dryness; and treat the dry mass with alcohol. Evaporate the alcoholic solution to dryness, and dissolve the residuum in water. The muriate of magnesia, if the water contained any, will be found in this solution. Let us suppose, that, by the tests formerly described, the presence of muriatic acid and of magnesia, in this solution, has been ascertained. In that case, if carbonate of lime afford no precipitate, and if sulphuric acid and evaporation, together with the addition of a little alcohol, occasion no precipitate, the solution contains only muriate of magnesia. If these tests give precipitates, we must separate the lime which is present by sulphuric acid and alcohol, and distil off the acid with which it was combined. Then the magnesia is to be separated by the oxalic acid and alcohol, and the acid with which it was united is to be distilled off. If the liquid in the retort give a precipitate with nitrate of silver, the water contains muriate of magnesia. Muriate of alumina may be discovered by saturating the water, if it contain an excess of alkali, with nitric acid, and by separating the sulphuric acid by means of nitrate of barytes. If the liquid, thus purified, give a precipitate with carbonate of lime, it contains muriate of alumina. The muriate of iron or of manganese, if any be present, is also decomposed, and the iron precipitated by this salt. The precipitate may be dissolved in muriatic acid, and the alumina, iron, and manganese, if they be present, may be separated by the rules laid down below.

3. To ascertain the presence of the different nitrates.—The nitrates but seldom occur in waters; but, when they do, they may be detected by the following results:—Alkaline nitrates may be detected by freeing the water examined from sulphuric acid by means of acetate of barytes, and from muriatic acid by acetate of silver. Evaporate the filtered liquid, and treat the dry mass with alcohol; what the alcohol leaves can consist only of the alkaline nitrates and acetate of lime. Dissolve it in water. If carbonate of magnesia occasion a precipitate, lime is present. Separate the lime by means of carbonate and magnesia. Filter and evaporate to dryness, and treat the dried mass with alcohol. The alcohol now leaves only the alkaline nitrates, which may be easily recognised, and distinguished by their

respective properties. Nitrate of lime.—To detect this salt, concentrate the water, and mix it with alcohol to separate the sulphates. Filter, and distil off the alcohol; then separate the muriatic acid by acetate of silver. Filter; evaporate to dryness; and dissolve the residuum in alcohol. Evaporate to dryness, and dissolve the dry mass in water. If this last solution indicate the presence of lime by the usual tests, the water contained nitrate of lime. To detect nitrate of magnesia, the water is to be freed from sulphates and muriates exactly as described in the last paragraph. The liquid thus purified is to be evaporated to dryness, and the residuum treated with alcohol. The alcoholic solution is to be evaporated to dryness, and the dry mass dissolved in water. To this solution potash is to be added, as long as any precipitate appears. The solution, filtered, and again evaporated to dryness, is to be treated with alcohol. If it leave a residuum consisting of nitre (the only residuum which it can leave), the water contained nitrate of magnesia. Such are the methods by which the presence of the different saline contents of waters may be ascertained. The labor of analysis may be considerably shortened, by observing that the following salts are incompatible with each other, and cannot exist together in water, except in very minute proportion:

Salts.	Incompatible with.
Fixed alkaline sulphates	Nitrates of lime and magnesia, Muriates of lime and magnesia.
Sulphate of lime	Alkalis, Carbonate of magnesia, Muriate of barytes.
Alum	Alkalis, Muriate of barytes, Nitrate, muriate, carbonate of lime, Carbonate of magnesia.
Sulphate of magnesia	Alkalis, Muriate of barytes, Nitrate and muriate of lime.
Sulphate of iron	Alkalis, Muriate of barytes, Earthy carbonates.
Muriate of barytes	Sulphates, Alkaline carbonates. Earthy carbonates.
Muriate of lime	Sulphates, except of lime, Alkaline carbonates, Earthy carbonates.
Muriate of magnesia	Alkaline carbonates, Alkaline sulphates.
Nitrate of lime	Alkaline carbonates, Carbonate of magnesia and alumina, Sulphates, except of lime.

Besides the substances above described, there is sometimes found in water a quantity of bitumen combined with alkali, and in the state of soap. In such waters acids occasion a coagulation; and the coagulum collected on a filter discovers its bituminous nature by its combustibility. Water also sometimes contains extractive matter; the presence of which may be detected by means of nitrate of silver. The water suspected to contain it must be freed from sulphuric and nitric acid by means of nitrate of lead: after this, if it give a brown precipitate with nitrate of silver, we may conclude that extractive matter is present.

But it is not sufficient to know that a mineral water contains certain ingredients; it is necessary to ascertain the proportions of these, and thus we arrive at their complete analysis. 1. The different aërial fluids ought to be first separated and estimated. For this purpose, a retort should be filled two-thirds with the water, and connected with a jar full of mercury, standing over a mercurial trough. Let this water be made to boil for a quarter of an hour. The aërial fluids will pass over into the jar. When the apparatus is cool, the quantity of air expelled from the water may be determined either by bringing the mercury within and without the jar to a level; or, if this cannot be done, by reducing the air to the proper density by calculation. The air of the retort ought to be carefully subtracted, and the jar should be divided into cubic inches and tenths. The only gaseous bodies contained in water are common air, oxygen gas, nitrogen gas, carbonic acid, sulphureted hydrogen gas, and sulphurous acid. The last two never exist in water together. The presence of either of them must be ascertained previously by the application of the proper tests. If sulphureted hydrogen gas be present, it will be mixed with the air contained in the glass jar, and must be separated before this air be examined. For this purpose the jar must be removed into a tub of warm water, and nitric acid introduced, which will absorb the sulphureted hydrogen. The residuum is then to be again put into a mercurial jar, and examined. If the water contain sulphurous acid, this previous step is not necessary. Introduce into the air a solution of pure potash, and agitate the whole gently. The carbonic acid and sulphurous acid gas will be absorbed, and leave the other gases. The bulk of this residuum, subtracted from the bulk of the whole, will give the bulk of the carbonic acid and sulphurous acid absorbed. Evaporate the potash slowly, almost to dryness, and leave it exposed to the atmosphere. Sulphate of potash will be formed, which may be separated by dissolving the carbonate of potash by means of diluted muriatic acid, and filtering the solution: 100 grains of sulphate of potash indicate 36·4 grains of sulphurous acid, or 53·66 cubic inches of that acid in the state of gas. The bulk of sulphurous acid gas ascertained by this method, subtracted from the bulk of the gas absorbed by the potash, gives the bulk of the carbonic acid gas. Now 100 cubic inches of carbonic acid, at the temperature of 60° and barometer thirty inches, weigh 46·6 grains. Hence it is easy to ascertain its weight. The gas remaining may be examined by the common eudiometrical processes. When a water contains sulphureted hydrogen gas, the bulk of this gas is to be ascertained in the following manner: fill three-fourths of a jar with the water to be examined, and invert it in a water trough, and introduce a little nitrous gas. This gas, mixing with the air in the upper part of the

jar, will form nitrous acid, which will render the water turbid, by decomposing the sulphureted hydrogen, and precipitating sulphur. Continue to add nitrous gas at intervals as long as red fumes appear, then turn up the jar and blow out the air. If the hepatic smell continue, repeat this process. The sulphur precipitated indicates the proportion of hepatic gas in the water; one grain of sulphur indicating the presence o nearly three cubic inches of this gas.

2. After having estimated the gaseous bodies, the next step is to ascertain the proportion of the earthy carbonates. For this purpose it is necessary to deprive the water of its sulphureted hydrogen, if it contain any. This may be done, either by exposing it to the air for a considerable time, or treating it with litharge. A sufficient quantity of the water, thus purified if necessary, is to be boiled for a quarter of an hour, and filtered when cool. The earthy carbonates remain on the filter. The precipitate thus obtained may be carbonate of lime, of magnesia, of iron, of alumina, or even sulphate of lime. Let us suppose all of these substances to be present together. Treat the mixture with diluted muriatic acid, which will dissolve the whole except the alumina and sulphate of lime. Dry this residuum in a red heat, and note the weight. Then boil it in carbonate of soda, saturate the soda with muriatic acid, and boil the mixture for half an hour. Carbonate of lime and alumina precipitate. Dry this precipitate, and treat it with acetic acid. The lime will be dissolved, and the alumina will remain. Dry it and weigh it. Its weight, subtracted from the original weight, gives the proportion of sulphate of lime. The muriatic solution contains lime, magnesia, and iron. Add ammonia as long as reddish precipitate appears. The iron and part of the magnesia are thus separated. Dry the precipitate, and expose it to the air for some time in a heat of 200°; then treat it with acetic acid to dissolve the magnesia; which solution is to be added to the muriatic solution. The iron is to be re-dissolved in muriatic acid, precipitated by an alkaline carbonate, dried and weighed. Add sulphuric acid to the muriatic solution as long as any precipitate appears; then heat the solution and concentrate. Heat the sulphate of lime thus obtained to redness, and weigh it: 100 grains of it are equivalent to 74·7 of carbonate of lime dried. Precipitate the magnesia by means of carbonate of soda. Dry it and weigh it. But, as part remains in solution, evaporate to dryness, and wash the residuum with a sufficient quantity of distilled water, to dissolve the muriate of soda and sulphate of lime, if any be still present. What remains behind is carbonate of magnesia. Weigh it, and add its weight to the former. The sulphate of lime, if any, must also be separated and weighed.

3. We have next to ascertain the proportion of mineral acids or alkalis, if any be present uncombined. The acids which may be present, omitting the gaseous, are the sulphuric, muriatic, and boracic. The proportion of sulphuric acid is easily determined. Saturate it with barytes water, and ignite the precipitate. 100 grains of sulphate of barytes, thus formed, indicate 34·0 of real sulphuric acid. Saturate the muriatic acid with barytes water, and then precipitate the barytes by sulphuric acid: 100 parts of the ignited precipitate are equivalent to 23·73 grains of real muriatic acid. Precipitate the boracic acid by means of acetate of lead. Decompose the borate of lead by boiling it in sulphuric acid. Evaporate to dryness. Dissolve the boracic acid in alcohol, and evaporate the solution; the acid left behind may be weighed. To estimate the proportion of alkaline carbonate present in a water containing it, saturate it with sulphuric acid, and note the weight of real acid necessary. Now 100 grains of real sulphuric acid saturate 120·0 potash, and 80·0 soda.

4. The alkaline sulphates may be estimated by precipitating their acid by means of nitrate of barytes, having previously freed the water from all other sulphates; for 14·75 grains of ignited sulphate of barytes indicate 9·0 grains of dried sulphate of soda; while 14·75 sulphate of barytes indicate eleven of dry sulphate of potash. Sulphate of lime is easily estimated by evaporating the liquid containing it to a few ounces (having previously saturated the earthy carbonates with nitric acid), and precipitating the sulphate of lime by means of weak alcohol. It may then be dried and weighed. The quantity of alum may be estimated by precipitating the alumina by carbonate of lime or of magnesia (if no lime be present in the liquid). Eleven grains of the alumina, heated to incandescence, indicate 100 of crystallised alum, or fifty-five of dried salt. Sulphate of magnesia may be estimated, provided no other sulphate be present, by precipitating the acid by means of a barytic salt, as 14·75 parts of ignited sulphate of barytes indicate 7·46 of sulphate of magnesia. If sulphate of lime, and no other sulphate, accompany it, this may be decomposed, and the lime precipitated by carbonate of magnesia. The weight of the lime, thus obtained, enables us to ascertain the quantity of sulphate of lime contained in the water. The whole of the sulphuric acid is then to be precipitated by barytes. This gives the quantity of sulphuric acid; and, subtracting the portion which belongs to the sulphate of lime, there remains that which was combined with the magnesia, from which the sulphate of magnesia may be easily estimated. If sulphate of soda be present, no earthy nitrate or muriate can exist. Therefore, if no other earthy sulphate be present, the magnesia may be precipitated by soda, dried and weighed; 2·46 grains of which indicate 7·46 grains of dried sulphate of magnesia. The same process succeeds when sulphate of lime accompanies these two sulphates; only in this case the precipitate, which consists both of lime and magnesia, is to be dissolved in sulphuric acid evaporated to dryness, and treated with twice its weight of cold water, which dissolves the sulphate of magnesia, and leaves the other salt. Let the sulphate of magnesia be evaporated to dryness, exposed to a heat of 400°, and weighed. The same process succeeds, if alum be present instead of sulphate of lime. The precipitate in this case, previously dried, is to be treated with acetic acid, which dissolves the magnesia, and leaves the alumina. The magnesia

may be again precipitated, dried, and weighed. If sulphate of iron be present, it may be separated by exposing the water to the air for some days, and mixing with it a portion of alumina. Both the oxide of iron and the sulphate of alumina, thus formed, precipitate in the state of an insoluble powder. The sulphate of magnesia may then be estimated by the rules above given. Sulphate of iron may be estimated by precipitating the iron by means of prussic alkali, having previously determined the weight of the precipitate produced by the prussiate in a solution of a given weight of sulphate of iron in water. If muriate of iron be also present, which is a very rare case, it may be separated by evaporating the water to dryness, and treating the residuum with alcohol, which dissolves the muriate, and leaves the sulphate.

5. If muriate of potash, or of soda, without any other salt, exist in water, we have only to decompose them by nitrate of silver, and dry the precipitate; for 18·4 of muriate of silver indicate 9·5 of muriate of potash; and 18·4 of muriate of silver indicate 7·5 of common salt. The same process is to be followed if the alkaline carbonates be present; only these carbonates must be previously saturated with sulphuric acid; and we must precipitate the muriatic acid by means of sulphate of silver instead of nitrate. The presence of sulphate of soda does not injure the success of this process. If muriate of ammonia accompany either of the fixed alkaline sulphates, without the presence of any other salt, decompose the sal ammoniac by barytes water, expel the ammonia by boiling, precipitate the barytes by diluted sulphuric acid, and saturate the muriatic acid with soda. The sulphate of barytes, thus precipitated, indicates the quantity of muriate of ammonia, 14·75 grains of sulphate indicating 6·75 grains of this salt. If any sulphates be present in the solution they ought to be previously separated. If common salt be accompanied by muriate of lime, muriate of magnesia, muriate of alumina, or muriate of iron, or by all these together, without any other salt, the earths may be precipitated by barytes water, and redissolved in muriatic acid. They are then to be separated from each other by the rules formerly laid down; and their weight, being determined, indicates the quantity of every particular earthy muriate contained in the water. For fifty grains of lime indicate 100 of dried muriate of lime; thirty grains of magnesia indicate 100 of the muriate of that earth; and 21·8 grains of alumina indicate 100 of the muriate of alumina. The barytes is to be separated from the solution by sulphuric acid, and the muriatic acid expelled by heat, or saturated with soda; the common salt may then be ascertained by evaporation, subtracting in the last case the proportion of common salt indicated by the known quantity of muriatic acid from which the earths had been separated. When sulphates and muriates exist together they ought to be separated either by precipitating the sulphates by means of alcohol, or by evaporating the whole to dryness, and dissolving the earthy muriates in alcohol. The salts thus separated may be estimated by the rules already laid down. When alkaline and earthy muriates and sulphate of lime occur together, the last is to be decomposed by means of muriate of barytes. The precipitate ascertains the weight of sulphate of lime contained in the water. The estimation is then to be conducted, as when nothing but muriates are present; only from the muriate of lime that proportion of muriate must be deducted which is known to have been formed by the addition of the muriate of barytes. When muriates of soda, magnesia, and alumina, are present together with sulphates of lime and magnesia, the water to be examined ought to be divided into two equal portions. To the one portion add carbonate of magnesia, till the whole of the lime and alumina be precipitated. Ascertain the quantity of lime which gives the proportion of sulphate of lime. Precipitate the sulphuric acid by muriate of barytes. This gives the quantity contained in the sulphate of magnesia and sulphate of lime: subtracting this last portion, we have the quantity of sulphate of magnesia. From the second portion of water precipitate all the magnesia and alumina by means of lime water. The weignt of these earths enables us to ascertain the weight of muriate of magnesia and of alumina contained in the water, subtracting that part of the magnesia which existed in the state of sulphate, as indicated by the examination of the first portion of water. After this estimation, precipitate the sulphuric acid by barytes water, and the lime by carbonic acid. The liquid, evaporated to dryness, leaves the common salt.

6. It now only remains to explain the method of ascertaining the proportion of the nitrates which may exist in waters. When nitrate accompanies sulphates and muriates, without any other nitrates, the sulphates are to be decomposed by acetate of barytes, and the muriates by acetate of silver. The water, after filtration, is to be evaporated to dryness, and the residuum treated with alcohol, which dissolves the acetates, and leaves the nitre, the quantity of which may be easily calculated. If an alkali be present it ought to be previously saturated with sulphuric or muriatic acid. If nitre, common salt, nitrate of lime, and muriate of lime or magnesia, be present together, the water ought to be evaporated to dryness, and the dry mass treated with alcohol, which takes up the earthy salts. From the residuum, redissolved in water, the nitre may be separated, and calculated as in the last case. The alcoholic solution is to be evaporated to dryness, and the residuum redissolved in water. Let us suppose it to contain muriate of magnesia, nitrate of lime, and muriate of lime. Precipitate the muriatic acid by nitrate of silver, which gives the proportion of muriate of magnesia and of lime. Separate the magnesia by means of carbonate of lime, and note its quantity. This gives the quantity of muriate of magnesia; and, subtracting the quantity of muriatic acid contained in that salt from the whole acid indicated by the precipitate of silver, we have the proportion of muriate of lime. Lastly, saturate the lime added to precipitate the magnesia with nitric acid. Then precipitate the whole of the lime by sulphuric acid; and subtracting from the whole of the sulphate thus formed that portion formed by

the carbonate of lime added, and by the lime contained in the muriate, the residuum gives us the lime contained in the original nitrate; and thirty-five grains of lime form 102·5 of dry nitrate of lime.

In the year 1807 Dr. Marcet advanced some new ideas on the art of analysing mineral waters, in an admirable paper on the water of the Dead Sea, inserted in the Philosophical Transactions. 'It is satisfactory to observe,' says this excellent chemist, 'that Dr. Murray adopted, several years afterwards, a mode of proceeding precisely similar, and indeed that he proposed, in a subsequent paper, a general formula for the analysis of mineral waters, in which this method is pointed out, as likely to lead to the most accurate results. And this coincidence is the more remarkable, as it would appear, from Dr. Murray not mentioning my labors, that they had not at that time come to his knowledge.'—*Philosophical Transactions*, 1819, part ii.

We prefix, after Dr. Ure, the results of the recent analysis by M. Berzelius of the waters of Carlsbad. They are very extraordinary, and he has found many substances not hitherto suspected to exist in them.

Sulphate of soda	2·58714
Carbonate of soda	1·25200
Muriate of soda	1·04893
Carbonate of lime	0·31219
Fluate of lime	0·00331
Phosphate of lime	0·00019
Carbonate of strontites	0·00097
Carbonate of magnesia	0·18221
Phosphate of alumina	0·00034
Carbonate of iron	0·00424
Carbonate of manganese	a trace
Silica	0·07504
	5·46656

Ann. de Chim. et Phys. xxi. 248.

The following table exhibits the compositions of the principal mineral waters as well as that of the sea. The reader will find, in the Philosophical Transactions for 1819, a very valuable dissertation on sea-water, by Dr. Marcet, of which a good abstract is given in the second volume of the Edinburgh Philosophical Journal. This philosopher shows that in Baffin's Bay, the Mediterranean Sea, and the tropical Seas, the temperature of the sea diminishes with the depth, according to the observations of Phipps, Ross, Parry, Sabine, Saussure, Ellis, and Peron; but that in the Arctic or Greenland Seas the temperature of the sea increases with the depth. This singular result was first obtained by Mr. Scoresby, in a series of well conducted experiments, and has been confirmed by the later observations of lieutenants Franklin and Beechy, and Mr. Fisher

TABLE of the Composition of the most celebrated MINERAL WATERS.

	Names of the Springs.	Grains of Water.	Cubic Inches of Gases. Oxygen.	Carbonic Acid.	Sulph. hydrogen.	Azote.	Carbonates of Soda. gr.	Lime. gr.	Magnesia. gr.	Iron. gr.	Sulphates of Soda. gr.	Lime. gr.	Magnesia. gr.	Iron. gr.	Muriates of Soda. gr.	Lime gr.	Magnesia. gr.	Potash. gr.	Silica. gr.	Alumina. gr.	Resins. gr.	Temperature.
Acidulous.	Seltzer[1]	8949	43·5	13·068			5·22	78·3	6·32			8·38			13·74							cold

An Alphabetical List of the Mineral Waters of Europe and their Qualities by Dr. Ryan.

Abcourt, St. Germain's, France, contains carbonate of iron and soda; is diuretic and aperient, and used in dropsy, jaundice, visceral obstructions, and eruptions.
Aberbrothick, Forfar, Scotland; a carbonated chalybeate, used in dyspepsia.
Acton, Middlesex, contains sulphate of magnesia and muriate of soda.
Aghaloo, Tyrone, contains sulphur, carbonate of soda, and aperient salts; used in scrofula.
Aix, in Provence; used in piles, diseases of the kidney and bladder, in fluor albus, excessive menstruation, and gonorrhœa; is somewhat similar to Plombieres.
Aix-la-Chapelle, Germany, contains carbonate of lime, muriate and carbonate of soda, and sulphur; is diaphoretic and purgative, and has been used in heartburn, asthma, ague, excessive menstruation; externally, in rheumatism, palsy, tremors, contractions, tumors, and cutaneous diseases.
Albermarle, or Aumale, Rouen, contains carbonate of iron.
Alford, or Awford, Somersetshire, is saline and strongly purgative.
Alvenan, Switzerland, is famous for bathing.
Annfield, Burrisoleigh, Tipperary, an excellent simple chalybeate.
Annaduff, Leitrim, is a sulphurous water.
Antrim, Ireland, contains muriate of soda, carbonate of lime, and bittern; has been used in dropsy, scurvy, jaundice, and visceral obstructions.
Ashwood, Fermanagh, is a saline and sulphurous water.
Ashton, Wiltshire, is a carbonated chalybeate water.
Askeron, Yorkshire, is a saline and sulphurous water.
Athlone, Roscommon, is a simple, weak chalybeate.
Athimonus, Leitrim, strongly sulphurous; much used in scrofula.
Austria is said to contain mineral waters, at Sellrain, Merain, Sexton, Prax, Agums, Brutz, Rabi, Pei, Stiria, Carinthia, and Carniola.
Baden, Germany, is a hot sulphurous water, resembling Aix-la-Chapelle.
Bagnigge, Middlesex, contains sulphate and muriate of magnesia; is aperient.
Baia, Italy, is a strong sulphurous water.
Balemore, Worcestershire, contains carbonate of iron; is strongly tonic.
Balaruc, near Montpelier, contains purging salts; is aperient and diuretic, has been employed in jaundice, palsy, scrofula, in diseases of the kidney and bladder, and externally in cutaneous affections.
Ballycastle, Antrim, is a chalybeate and sulphurous water; its effects are like Balemore.
Ballynahinch, Down, contains iron, carbonic acid, and sulphur; has been praised in scorbutic and dyspeptic cases. There is also a pure chalybeate in its vicinity.
Ballyspellan, Johnstown, Kilkenny, contains iron, carbonic acid, and muriate of soda; has been greatly esteemed in dyspepsia, chlorosis, lowness of spirits, and visceral obstructions.
Bagniers, Upper Pyrenees, said to be similar to Aix-la-Chapelle.
Bagnols, Guard, France, is a tepid, sulphurous water, and used in phthisis, affections of kidney, psora, palsy, and rickets.
Bandola, Italy, contains carbonic acid, iron, soda, and sulphur; is aperient, diaphoretic, and diuretic.
Bandon, Cork, is a simple chalybeate water.
Barèges, France, on the Pyrenees, contains muriate and carbonate of soda, lime, and sulphur; its temperature 115°; it is said to be similar to Bath. It has been used in nervous, œdematous, and cutaneous affections; in visceral obstructions, in rheumatism, chlorosis, and consumption; is aperient and diuretic.
Barnet, Hertfordshire, contains sulphate of magnesia and carbonate of lime.
Barrowdale, Cumberland, contains muriate of soda in great quantity, and carbonate of lime.
Bath, Somersetshire, contains carbonic acid, azotic gas, sulphate and muriate of soda, siliceous earth, selenite, carbonate of lime, and oxide of iron; temperature, 112° to 116°.—Saunders on Mineral Waters. It is diuretic, sudorific, and aperient; but, if drunk in small quantities at the commencement, it induces constipation and stupor. It has been employed in diseases of the stomach, liver, and bowels; in gout, rheumatism, and partial paralysis; in chlorosis, and, according to the excellent Treatise of Dr. Barlow on Bath Waters, in chronic eruptions.
Bologne, near Calais, contains carbonate of iron.
Bigova, Russia, a similar water to the last named.
Bonnes, Lower Pyrenees, similar to Bareges; temperature, 102°.
Bourbon l'Archambaud, near Moulins, is saline, and has been used in diseases of the liver, jaundice, bowel affections, and apoplexy.
Bourbonne Lancy, is aperient, diuretic, and emmenagogue; has been used in cachexia, diarrhœa, fluor albus, œdema, and asthma. Externally, in palsy, tremors, rheumatism, and cutaneous affections.
Bourbonne, France, is a warm, saline, and sulphurous water.
Borset, near Aix-la-Chapelle, a warm, alkaline, and sulphurous water; 132°.
Brentwood, Essex, contains sulphate of magnesia and lime; purgative
Brighton, a chalybeate.
Bristol, Somersetshire, contains lime, muriate of soda, sulphate of magnesia, and selenite; temperature, 74°. It has been considered as a specific in consumption; allays hectic; is used in bilious diarrhœa, dysentery, diabetes, calculous and cancerous disorders, and fluor albus.
Bromley, Kent, a carbonated chalybeate; is diuretic and corroborative.
Broughton, Yorkshire, said to be similar to Harrowgate.
Brownstown, Kilkenny, contains carbonate of iron, lime, magnesia, and muriate of soda. It has been used with advantage in stomach, liver

or other visceral diseases; in calculous and uterine disorders; and against tœnia lumbricus.

Buxton, Derbyshire, contains muriate and carbonate of soda, and lime; temperature, 82°; is praised in gout and rheumatism, and in diseases where bathing is useful.

Buda, in Hungary, is famed for its excellent baths.

Buzot, Spain, is a warm chalybeate water.

Caldas, also famed for baths, Portugal, contains sulphur, gas, argilla, and muriate of soda; it is famed for chronic rheumatism and dyspepsia.

Calabria, Italy, a saline water, containing sulphate of soda.

Cape Clear, a saline, purgative water.

Carlsbad, Germany, a warm, alkaline, aperient water.

Caroline baths, Bohemia, contain iron, carbonic acid, carbonate of lime, muriate and carbonate of soda, carbonate and sulphate of magnesia; are used in scrofula, dyspepsia, &c., in baths.

Carrickfergus, Antrim, from its blue color, said to contain copper.

Carrickmore, Cavan, contains carbonate of soda; is aperient.

Cartmel, Lancashire, contains muriate of soda and Epsom salts.

Castlecomer, Kilkenny, situated in the beautiful and classic demesne of the dowager countess of Ormond and Ossory. It was analysed by the late professor Higgins, of the Royal Dublin Society, and was found to contain iron, carbonic acid, and muriate of soda; results which I observed from my own experiments; and Drs. Wade, Garnet, and Ryan, thought it one of the best chalybeates in Ireland.

Castleconnel, Limerick, contains carbonate of iron; is said to resemble the German spa, and has been very much frequented for many years.

Castleleod, Rosshire, Scotland, contains carbonate of soda and sulphur.

Castlemain, Kerry, contains iron, sulphur, and carbonic acid.

Cawley, Derbyshire, contains sulphate of magnesia and sulphate of lime.

Cawthorp, Lincolnshire, contains iron, carbonic acid, and carbonate of soda; is aperient and antacid.

Cavan Spa is a chalybeate.

Cautères, Upper Pyrenees, near Bagnieres, is a warm water; temperature 102° to 120°. Is much praised in acidity of the stomach, asthma, consumption, suppression of mènses, and cutaneous affections.

Chadlington, Oxfordshire, contains carbonate and muriate of soda, and sulphur; is an aperient.

Chaude Fontaine, Germany, same as Aix-la-Chapelle.

Cheltenham, Gloucestershire, contains calcareous earth, iron, sulphate of magnesia, and muriate of soda; is aperient and tonic, and much used in dyspepsia, bilious complaints, scurvy, and gravel.

Chippenham, Wiltshire, contains carbonate of iron.

Clashmore, Waterford, said to contain sulphate of iron, by Elliot.

Cleves, Germany, similar to Pyrmont.

Clifton, near Bristol; to which it is similar.

Clonmell, Tipperary, a sulphurous water, much praised for scrofula.

Cobham, Surrey, contains iron and purging salt.

Codsalwood, Staffordshire, resembles Askeron water.

Colchester, Essex, contains sulphate of magnesia and carbonate of lime.

Coalcullen, Kilkenny, is a carbonated chalybeate.

Cork county contains many mineral waters, not given in this account, of minor note. (See my Treatise on the Mineral Waters of Ireland, 1824, Longman).

Corstophine, Mid Lothian, contains sulphur and sulphate of magnesia.

Corville, Roscrea, Tipperary, a simple chalybeate water.

Coventry, Warwickshire, contains carbonate of iron and purging salt.

Cransac, Aveiron, contains carbonate of iron and sulphur.

Crosstown, Waterford, contains sulphate of iron; is diuretic and purgative.

Daswild Bad, Germany, contains carbonate of iron and saline matter; in visceral diseases.

Dax, near Bayonne, similar to Aix-la-Chapelle; discharges 543 cubic feet of water in fifteen minutes; is exhibited in affections of the kidney, in asthma, palsy, and rheumatism, in baths.

Deddington, Oxford, contains iron, sulphur, carbonated earth, muriate and carbonate of soda; greatly praised in cutaneous diseases.

Derby, Derbyshire, contains carbonate of iron.

Derryinch, Fermanagh, contains sulphur and carbonate of soda.

Derrindaff, Cavan, contains sulphur and purging salt.

Derrylester, Cavan, a strongly sulphurous water.

Digne, Lower Alps, warm, saline, and sulphurous; aperient and diuretic. Is used in dyspepsia, scrofula, asthma, visceral obstructions, and eruptions.

Dog and Duck, near London, contains sulphate of magnesia and muriate of soda; it is said to be a cooling purgative.

Doneraile, Cork, a chalybeate.

Drigwell, Cumberland, similar to Deddington.

Driburgin, Westphalia, a saline chalybeate.

Dronisnamullock, Leitrim, a very strong sulphurous water.

Droppingwell, Yorkshire, contains carbonated earth; is astringent and tonic.

Drumasnave, Leitrim, one of the strongest sulphurous waters in Ireland.

Dudley, Worcestershire, sulphurous and chalybeate.

Dublin salt springs, Francis Street, and Hanover Lane waters.

Dulwich, Kent, contains muriate of soda and sulphate of magnesia.

Dunnard, Dublin, a simple carbonated chalybeate.

Dunse, Scotland, contains iron, muriate of soda, and bittern.

Durham contains sulphur and muriate of soda. A saline spring there.

Egra, Bohemia, said to be similar to Cheltenham.
Ems, Germany, famed for sulphurous baths.
Emsem, Germany, properties not described.
Enghien, Netherlands, contains sulphureted hydrogen.
Epsom, Surrey, contains muriate and sulphate of magnesia.
Fairburn, Rosshire, Scotland, contains sulphur and sulphate of soda.
Fahara, Switzerland, famed for baths.
Felstead, Essex, similar to Islington.
Filah, Yorkshire, is powerfully diuretic and aperient.
Forgès, Rouen, contains carbonate of iron.
Frankfort, Germany, is similar to Harrowgate.
Gainsborough, Lincolnshire, contains sulphur, iron, and Epsom salts.
Geyser, Iceland, contains pure soda.
Galway is similar to Tunbridge.
Garryhill, Carlow, a chalybeate.
Glastonbury, Somersetshire, similar to Clifton.
Glendy, Kincardine, Scotland, similar to Peterhead.
Granshaw, Ireland, similar to the German Spa.
Gran, Hungary, not described.
Grossal, Germany, a calcareous water.
Haigh, Lancashire, contains carbonate and sulphate of iron; is emetic.
Hampstead, Middlesex, similar to last-named.
Hanbridge, Lancashire, similar to Scarborough; is less aperient.
Hanlays, Shropshire, contains purging salts, is aperient.
Harrowgate, Yorkshire, discovered 1571, by captain Slingsby; found to contain sulphur, muriate of soda, and purging salt. It is alterative and purgative; destroys worms; is praised in scurvy, scrofula, palsy, and chiefly in cutaneous diseases.
Hartfell, Scotland, contains sulphate of iron; is astringent and tonic, and used in all internal hæmorrhages.
Hartlepool, Durham, contains sulphur, iron, and carbonic acid.
Healinglake, Cavan, cures scrofula, and is attested by many respectable persons.
Holt, Wiltshire, is mildly purgative, and used in ulcers and eruptions.
Jerpoint Abbey spa, Kilkenny, is a strong sulphurous water.
Italy contains many sulphurous and warm springs, of little note.
Joseph's-well, Surrey, contains a large portion of sulphate of magnesia.
Johnstown, see *Ballyspellan.*
John's-well, Kilkenny, same as Johnstown; not so strong.
Ilmington, Warwickshire, contains carbonate of iron and soda.
Inglewhite, Lancashire, a sulphurous chalybeate.
Islington, near London, contains carbonate of iron; is tonic and diuretic.
Kanturk, Cork, contains iron and sulphur; used in scrofula and eruptions.
Kedlestone, Derbyshire, is similar to Harrowgate.
Kensington, near London, is similar to Acton.
Kilbrew, Meath, similar to Shadwell.
Kilburn, England, a sulphurous and saline water.
Kilcoran, Clare, a chalybeate.
Kilagee, Down, a chalybeate.
Killashen, Fermanagh, a sulphurous water.
Kileshan, Queen's County, a weak chalybeate.
Kilkenny college and canal spas, sulphurous and chalybeate.
Kilroot, Antrim, is similar to Barrowdale.
Kinalton, Nottinghamshire, a saline aperient water.
Kilmainham, Dublin, a sulphurous chalybeate.
Kincardine, Scotland, similar to Peterhead.
Kingscliff, Northamptonshire, similar to Cheltenham.
Kirkby, Westmoreland, a saline chalybeate.
Knaresborough, see *Droppingwell.*
Klintschyselo, Russia, warm springs at.—*Clarke's Russia.*
Knowsley, Lancashire, same as Scarborough.
Kuka, Bohemia, contains carbonate of soda; is diaphoretic and sialagogue.
Lancaster, similar to Tunbridge.
Langeac, Upper Loire, a cold acidulous water.
Latham, Lancashire, similar to Tunbridge.
Leuck, Switzerland, not described chemically.
Llanndridad, Wales, a sulphurous chalybeate.
Lucca, Italy, a warm spring.
Llangybi, Wales, properties unknown.
Lisbeak, Fermanagh, strongly sulphurous.
Lemington, Warwickshire, contains muriate of soda and carbonate of lime; is strongly aperient, and much frequented.
Leez, Essex, same as Islington.
Listerlin, Kilkenny, a chalybeate.
Loansbury, Yorkshire, is sulphurous and aperient, used in eruptions.
Lough Neagh, Down, said to cure running ulcers.
Madrid, a mineral water there contains sulphate of soda very largely.
Mallow, Cork, is similar to Bristol; discovered 1689, by Dr. Rogers, of Cork, one of whose patients drank of the water accidentally. It discharges twenty gallons in the minute; is clear and limpid when drawn from the fountain, with a vapor arising from it. I have seen the most decided good effects from this water in consumptive habits, even in cases which were considered hopeless. It is used in the same manner as the Bristol water.
Maherabeg, Kerry, is a saline aperient water.
Malvern, Worcestershire, contains carbonic acid, lime, and magnesia, united with carbonic and muriatic acids; is tonic and diuretic. Is used in muco-purulent affections of the bladder, in hectic and consumptive cases; in bilious and female diseases; in scrofulous and chronic eruptions.
Markshall, Essex, same as Islington.
Maudley, Lancashire, sulphurous and saline.
Matlock, Derbyshire, similar to Bristol; temperature 66°.
Micham, Fermanagh, a sulphurous water.
Miers, France, aperient and diuretic.
Millar's Spa, Lancashire, same as Tunbridge.
Miltown Malbay, Clare, a chalybeate water.
Moffat, Annandale, Scotland, contains sulphur, muriate of soda, and an earth. Is alterative, diuretic, and purgative; is used as a bath.
Mont d'Or, France, same as Aix-la-Chapelle.
Mont Pallas, Cavan, a chalybeate water.

Montmorency, Paris, a sulphurous spring.
Monfrin, Nimes, France, is aperient and diuretic.
Mosshouse, Lancashire, same as Islington.
Moreton, Shropshire, similar to Holt.
Motte, near Grenoble, is a warm sulphurous water.
Neville Holt, Leicestershire, contains carbonated earth and Epsom salts.
Naphtha, Russia, a chalybeate.
New Cartmel, Lancashire, saline and aperient.
Naples, a sulphurous and chalybeate water, near St. Luke's church.
Newnham Regis, Warwickshire, similar to Scarborough.
Newtondale, Yorkshire, contains carbonate of lime and magnesia.
Newtown Stewart, Tyrone, is similar to Tunbridge.
Nezdenice, Germany, carbonate of iron and soda; diuretic and tonic.
Nobber, Meath, is similar to Hartfell.
Nocaria, Italy, famed for baths.
Normandy, Yorkshire, is similar to Askeron water.
Nottingham, Dorsetshire, sulphurous and saline: used in eruptions.
Oakfield, Cavan, a chalybeate.
O'Brien's Bridge, Clare, a strong sulphurous water.
Oersten, Denmark, little frequented.
Orston, Nottingham, contains carbonic acid in excess, iron, and sulphate, and muriate of soda. It induces intoxication.
Oulton, Norfolk, same as Islington.
Owen Bruen, Cavan, same as Askeron.
Pancras, London, contains sulphate of magnesia and carbonated earth.
Peterhead, Aberdeen, a strong chalybeate.
Passi, near Paris, similar to Pyrmont and Cransac.
Perekop, Russia, a chalybeate.
Pettigre, Donegal, same as Askeron.
Phœnix Park, Dublin, a chalybeate and sulphurous water.
Pisa, Italy, a warm spring: also famed for baths.
Pithkeatly, Perthshire, Scotland, contains muriate of soda, and an earth.
Plombieres, Lorraine, France, a saline and sulphurous warm spring; used in affections of the bladder and asthma; and externally in scrofula and cutaneous diseases.
Pontgibault, France. There are thirty-two springs here, whose temperatures vary from 82° to 124°; their effects are diuretic and laxative.
Pongues, Nivernois, France, contains calcareous earth, magnesia, carbonate of soda, muriate of soda, and siliceous earth; diuretic and aperient.
Pyrmont, Westphalia, contains carbonate of iron, calcareous earth, magnesia, sulphate of magnesia, and muriate of soda. It is diuretic, diaphoretic, and aperient; and used in female complaints, in relaxed habits, in cutaneous and nervous diseases, urinary obstructions; and considered the best restorative in broken constitutions.
Prussia, Warmburn; the only mineral water there.
Queen Carmel, Somersetshire, contains sulphur, muriate of soda, and calcareous earth; is used in scrofulous and cutaneous affections.
Richmond, Surrey, same as Acton.
Rippon, Yorkshire, sulphurous and saline.
Riviera de Abajo, Spain, near Oviedo; said to be similar to Bath.
Road, Wiltshire, a sulphurous and chalybeate water; very strong.
Rykum, Iceland, contains pure soda.
St. Amands, Valenciennes, sulphurous; is used in eruptions, calculous cases, and piles.
St. Bartholomew's, Cork, same as Tilbury.
St. Bernard's, Edinburgh, is a strong sulphurous water, same as Harrowgate; and is used in scorbutic and scrofulous diseases.
St. Erasmus' Well, Staffordshire, same as Barrowdale.
St. Windfrede's, Wiltshire, resembles Malvern.
Sarepta, Russia, a chalybeate.
Scarborough, Yorkshire, contains carbonate of lime, sulphates of magnesia and soda, and iron; is diuretic and purgative.
Scolliensis, Switzerland, contains iron, carbonate of soda, and carbonic acid.
Scool, Clare, is a chalybeate. Sea-water, which contains muriate of soda and magnesia, and selenite.
Sedlitz, Bohemia, contains sulphate of magnesia, and is strongly purgative; is used in stomach, nervous, hemorrhoidal, and œdematous complaints, and in anomalous cases succeeding cessation of the menses.
Seltzer, Germany, contains carbonic acid, carbonate of soda, calcareous earth, and magnesia; is used in gravel, hæmaturia, scurvy, scrofula, dyspepsia, heartburn, acidity, and in billious and calculous disorders.
Sene, or Sende, Wiltshire, is similar to Islington.
Scydschutz, Germany, same as Sedlitz.
Shadwell, near London, contains sulphate of iron.
Shapmoor, Westmoreland, is sulphurous and saline; same as Askeron.
Shettlewood, Derbyshire, is similar to Harrowgate.
Shipton, Yorkshire, same as last-named.
Skibbereen, Cork, a sulphurous water.
Somersham, Huntingdonshire, contains sulphate of iron; applied to old ulcers.
Spa, Germany, contains carbonate of soda, iron, carbonated earth, sulphate of magnesia, and muriate of soda; is used in suppression and retention of menses, hysterical and dropsical affections, and fluor albus.
Spain contains several waters of little note.
Stanger, Cumberland, contains sulphate of iron.
Stenefield, Lincolnshire, similar to Orston.
Streatham, Surrey, contains carbonated earth, sulphate and muriate of magnesia.
Suchaldza, Hungary, similar to Nezdenice.
Sweden mineral waters, said to contain muriate of potass.
Swansea, Glamorganshire, similar to Shadwell.
Swabia, Baden, is a warm sulphurous water; temperature 132°.
Sydenham, Kent, is similar to Epsom.
Tarleton, Lancashire, is similar to Scarborough.
Teutuccia, Italy, famed for baths.
Tewksbury, Gloucestershire, similar to Acton.
Thetford, Norfolk, contains carbonate of soda and iron, and carbonic acid.

Thorston, Nottingham, same as Orston.
Thursk, Yorkshire, same as Scarborough.
Tilbury, Essex, contains carbonate of soda; is diuretic and diaphoretic.
Tibshelf, Derbyshire, is similar to Spa.
Toberbony, Dublin, is an alkaline water.
Tonstein, Germany, is similar to Seltzer.
Toplitz, Bohemia, a saline water; famed also for baths.
Tralee, Kerry, is similar to Castleconnel.
Tunbridge, Kent, contains iron, muriate of soda, and calcareous earth; used in all diseases in which chalybeates are serviceable.
Turkey, waters of, very little known.
Vals, Dauphiny, contains carbonate of soda; is diuretic and diaphoretic.
Vesoul, Upper Soane, is aperient, refrigerant, and diuretic.
Vichy, near Moulins, contains carbonate of soda and sulphate of iron; is used in jaundice, affections of the kidney and bladder, and in sterility.
Viterbo, in Italy, said to contain sulphurous acid.
Wardrew, Northumberland, is similar to Harrowgate.
Wellingborough, Northamptonshire, same as Islington.
West Ashton, Wiltshire, similar to last-named.
Westwood, Derbyshire, same as Shadwell.
Wexford spa, is said to be like Islington.
Wisbaden, Germany, a carbonated water; is famed for baths.
Whiteacre, Lancashire, contains carbonate of iron and lime.
Wildungen, Germany, said to be similar to Bath.
Wildbad, Germany, famed for warm baths.
Witham, Essex, contains carbonate of iron and muriate of soda.
Wirksworth, Derbyshire, sulphurous, saline, and chalybeate.
Wurtemburg, Germany, famed for baths.
Zahorovice, Germany, similar to Nezdenice.

Mineral Waters, Artificial. *To imitate closely Cheltenham water.*—Take Epsom salts 12 grs., iron filings 1 gr., Glauber salts 4 oz., water 4 gals.; mix and impregnate with the gas arising from 2 oz. oil of vitriol, and 2 oz. powdered marble.

Artificial Harrowgate water.—Take common salt 5 oz., water 3 pints; impregnate with gas from liver of sulphur and oil of vitriol, of each 4 oz.

Artificial Pyrmont water.—Take Epsom salts 15 grs., common salt 5 grs., magnesia 10 grs., iron filings 5 grs., water 3 pints; mix and impregnate with gas of marble and oil of vitriol, of each 7 drachms. For further information on this part of the subject, see *Forsyth's Dieteticon*, *Thomson's London Dispensatory* for 1826, &c.

MINERALOGY.

Mineralogy is that department of natural history which teaches us to describe, recognise, and classify the different objects of inorganic nature. The mineral kingdom can never be confounded with either of the others; it comprises within its limits mere masses of dead unorganised matter, subject, as far as we are able to judge, to the laws of chemistry alone, and increasing only by the mechanical addition of extraneous substances; they are not fed by nourishment, nor modified by internal operations, nor supported by any known principle of vitality. Modern mineralogists, indeed, consider this science to treat not only of the earthy and stony substances, which the vulgar have been in the habit of styling minerals, but also of atmospheric air, water, the sulphuric and muriatic acids, and even of hydrogen and carbonic acid gas; at the same time earths loosely aggregated, minerals and many clays, are said to be more properly objects of geological curiosity and economical value, than interesting to the mineralogist (Jameson). We confess this seems to us 'passing strange;' but more of the reigning systems anon.

From a superficial view of minerals in their natural deposits at or near the surface of the earth, it would hardly be supposed possible to arrange them in orders or classify them in groups. Nothing appears further removed from the influence of uniform laws or established principles, than the mineral kingdom, when cursorily observed. It consists of bodies aggregated, not organised, and collected together without the slightest apparent arrangement. All at the first glance appears confusion, while

> Hot, cold, moist and dry, four champions fierce
> Strive here for mastery, and to battle bring
> Their embryon atoms.

But a closer inspection and more comprehensive view of the subject, will convince us that this is 'harmony not understood,' and that this portion of his works is not without the impress of the Deity. To be convinced that the mineral kingdom affords suitable objects for scientific research, we need but glance at two or three of its most interesting phenomena. The properties which some minerals possess of phosphorescence, electricity, and magnetism, may serve to excite the attention of the curious, while the ablest mathematician may find ample employment in the more abstruse problems of crystallisation and polarised light. This is, at the same time, the science which includes within its ample range, the marbles of the statuary and architect, the metals of the manufacturer, the gems of the jeweller, and the soils of the agriculturist. It can never, therefore, be deemed uninteresting or unimportant. Nothing can be more beautiful than the caverns to be met with in primitive rocks, whose walls are lined with pure and variously colored crystallised topaz, beryl, and rock crystal; and the gneiss, granite, and mica slate, with their embedded grains and crystals of sapphire, chrysoberyl, garnet, emerald, axinite, and ruby, seem to realise the oriental tales of diamond valleys and emerald caves. But

it is not the beauties of the gems alone that attract our attention; the varying composition of the mighty masses which compose the crust of the earth's surface, and their conversion into soils, the operations at once mighty and minute which turn the hard and sterile rock into soft and fertile earth, are well worthy of notice. Some idea may be conveyed of the method in which this is performed, by referring to the instance of porcelain granite. 'This substance,' says Sir Humphry Davy, 'consists of three ingredients, quartz, feldspar, and mica. The quartz is almost pure siliceous earth in a crystalline form. The feldspar and mica are very compounded substances; both contain silica, alumina, and oxide of iron; in the feldspar there are usually lime and potassa; in the mica lime and magnesia. When a granite rock of this kind has been long exposed to the influence of air and water, the lime and the potassa contained in its constituent parts are acted upon by water or carbonic acid; and the oxide of iron, which is almost always in its least oxidised state, tends to combine with more oxygen; the consequence is, that the feldspar decomposes, and likewise the mica; but the first the most rapidly. The feldspar, which is as it were the cement of the stone, forms a fine clay; the mica, partially decomposed, mixes with it as sand; and the undecomposed quartz appears as gravel or sand, of different degrees of fineness. As soon as the smallest layer of earth is formed on the surface of a rock, the seeds of lichens, mosses, and other imperfect vegetables which are constantly floating in the atmosphere, and which have made it their resting place, begin to vegetate; their death, decomposition, and decay, afford a certain quantity of organisable matter, which mixes with the earthy materials of the rock; in this improved soil, more perfect plants are capable of subsisting; these in their turn absorb nourishment from water and the atmosphere; and, after perishing, afford new materials to those already provided: the decomposition of the rock still continues; and at length, by such slow and gradual processes, a soil is formed in which even forest-trees can fix their roots, and which is fitted to reward the labors of the cultivator.'

Mineralogy is, however, almost the creation of the last fifty years. Previous to the year 1780, though tolerably understood by many as an art, it could scarcely be deemed a science, being, for want of precise definitions of its objects, incapable of communication; the same substance, from slight variation of appearance, was often denoted by different names, and different substances by the same name; its descriptive language was, for the most part, arbitrary, vague, and ambiguous, each author using that which seemed to him best to answer his purpose. To obviate the confusion thence arising, chemical tests were applied; but even these were found in many cases insufficient, unless the substances exposed to them were thoroughly analysed, a work of great difficulty, involving an intolerable length of time, and, when executed, demonstrative only of the individual substance to which it was applied. When any new specimen occurred, it might still be questioned whether it was or was not of the same nature as that already analysed; recourse must then have been had to description, and thus the same inconveniences recurred.

Since the time of Werner, however, the progress of this science has been rapid, owing greatly to the discoveries in chemistry, but still more to the orderly arrangements and sober attention to facts evinced in the works of the more modern mineralogists. An excessive fondness for theorising, unconnected with accurate observation, was the sin of the scientific writers of the sixteenth and seventeenth centuries; and mineralogy, in common with several other of the physical and experimental sciences, has had more difficulty in removing the rubbish her ill-judging admirers had placed in her way, than in overcoming the natural obstructions of the path. Limestone, for example, was formerly considered as entirely the result of animal action, and the various formations of that rock were viewed as accumulations of altered shells and corals. But neither shells nor corals occur in primitive mountains, although they often contain extensive beds of limestone, and although lime has been proved to enter into the composition of most of the simple minerals of which primitive rocks are composed. It is therefore evident that lime is an original substance in primitive mountains, and has been formed at times independently of animals.

Before the discovery of potassa in lepidolite, a primitive mineral, by Klaproth, this alkali was also considered as entirely a production of the vegetable kingdom; but no vegetable remains occur in primitive rocks; and, therefore, in this case, the potash has been formed by some other agency than that of vegetation. Phosphate of lime, the principal constituent of the bones of animals, was also maintained by the ancient chemists to be invariably an animal production. It, however, has been found in large masses in the primitive formations, and is thus proved to exist in nature, independently of the agency of the organic kingdom.

In this treatise we shall submit to the reader 1st. A history of mineralogy, embracing an account of all the celebrated earlier systems. 2dly. An analysis and comparison of the modern systems. And 3dly, An arrangement and brief notice of the known mineral substances. This will, of course, include only the simple minerals, the description of the compound masses, which form the crust of the earth, having been already given at considerable length in the article GEOLOGY, to which we refer the reader.

PART I.

HISTORY OF MINERALOGY.

The knowledge of some mineral substances must, of course, have been coeval with the earliest ages of the world. Tubal Cain probably discovered the difference between metals, earths, and stones; but the ancients appear to have been totally unacquainted with any thing in the shape of systematic mineralogy; and during the dark ages but little regard was paid to the scanty information to be gleaned from the works of Pliny and Theophrastus. It was not, indeed,

until the introduction of the Arabian chemistry, or alchemy, that any valuable attention was devoted to the study of unorganised bodies.

Avicenna, the 'Prince of Arabian philosophy,' in the eleventh century, divided minerals into four classes, viz. stones, salts, sulphureous or inflammable bodies, and metals; and this arrangement was generally adopted by the chemists of those times. Agricola, the first systematic writer this science can boast, was also the first who paid attention to the external characters of mineral substances. He divided them into simple or homogeneous minerals, and compound or heterogeneous minerals. The simple minerals he divided again into 1. Terra. 2. Succus concretus. 3. Lapis. And 4. Metallum. 'Terra' he defines as a fossil body, which when moistened with water can be rubbed down in the hand, or with which mud may be formed. 'Succus concretus' he calls a dry and moderately hard fossil, which, when moistened with water, either is not softened, or if softened, differs much from the 'terra' in its consistence, or in its composition. 'Lapis' is a fossil, hard and dry, which either long exposure to water scarcely softens, and violent heat converts to dust, or which water cannot soften, but which intense heat melts. 'Metallum' he considers as a fossil by nature, either liquid or hard, but which melts at a violent heat. He divides compound minerals into 1. 'Mixtures of stones and juices (succi).' 2. 'Mixtures of stones and metal.' 3. 'Mixtures of earth and metal.' And 4. 'Mixtures of juice, stone, and metal.' Such is the system of George Agricola; and though his total ignorance of chemical science occasionally led him into error, still it is valuable as the first attempt at mineralogical arrangement, while the logical precision of its execution is such as but few of our modern treatises exhibit.

The celebrated botanist Cæsalpinus was the first who properly separated the salts from the inflammable fossils. The divisions of his system are 1. Mineralia humore solubilia, i. e. minerals dissolvable in water, among which he includes the earths and salts. 2. Mineralia oleo solubilia, i. e. those dissoluble in oil, which contain sulphureous substances, orpiment, &c. 3. Illiquibilia, that cannot be melted, comprehending the rocks, all stones, corals, &c. And 4. Liquibilia, that can be melted, including only the metals.

Many writers on mineralogy appeared at the close of the seventeenth, and the beginning of the eighteenth century. The most celebrated perhaps of these was Joachim Becher, whose Physica Subterranea, in which he proposed to arrange mineral substances on chemical principles, passed through several editions. The stones he divides into 1. 'Those that either calcine or vitrify by heat.' 2. 'Those that preserve their solidity or become friable when ignited.' And 3. 'Those that when ignited, and immersed in water, either remain solid or crumble to pieces.' In his work we, for the first time, find antimony, zinc, and bismuth, classed as semi-metals, and mercury as a compound or decomposed body. The perfect metals of which he has but six, are thus ingeniously distinguished; two of them, gold and silver, melt in a red heat; two, copper and iron, are red-hot before they melt; and two, tin and lead, melt before they can be brought to a red heat. Next he treats of the decomposita, or such minerals as are composed of different earths and stones, earths and metals, or mixtures of metals, and they are divided into terrea, lapidea, metallica, and aquea.

In 1730 Magnus Van Bromell, a pupil of Boerhaave, published a system of mineralogy, in which he not only availed himself of the labors of his predecessors, but also proposed a new chemical division of stony substances into such as are refractory (apyri), such as are calcinable, and such as are vitrescible in the furnace.

After Van Bromell, Linnè appeared, who, in his earlier years, devoted a considerable share of time to the study of mineralogy; and, although his arrangement of the mineral kingdom is far inferior to his masterly systems of zoology and botany, yet this science acquired, through his works, a degree of notice and popularity it had never before enjoyed. It has been justly urged against the applicability of his system, that it is founded on an erroneous principle, viz. on the supposition that the crystalline form of mineral substances is always due to different salts, and that they are to be classed accordingly; but even this error served to direct attention to the important characters derived from the diversity of crystallisation, of which subsequent mineralogists have availed themselves for the distinction and classification of mineral substances. It was in 1736 that his system first appeared, and in this he arranges fossil bodies in three classes, namely petræ, mineræ, and fossilia. These were again subdivided into petræ vitrescentes, calcariæ, and apyræ. Mineræ salia, sulphurea, and mercurialia. And fossilia concreta, petrifacta, and terrestria. This arrangement, however, did not meet with his own final approval; for, in 1768, he published the following system, in which he preserved the outline of his three classes, but altered materially their subdivisions.

Class I. PETRÆ.

Order I. Humosæ.
1. Schistus.

Order II. Calcariæ.
2. Marmor,
3. Gypsum,
4. Stirium,
5. Spatum.

Order III. Argillaceæ.
6. Talcum,
7. Amiantus,
8. Mica.

Order IV. Arenatæ.
9. Cos,
10. Quartzum,
11. Silex.

Order V. Aggregatæ.
12. Saxum.

Class II. MINERÆ

Order I. Salia.
13. Nitrum,
14. Natrum,
15. Borax,
16. Muria,
17. Alumen,
18. Vitriolum.

Order II. Sulphura.
19. Ambra,
20. Succinum,
21. Bitumen,
22. Pyrites,
23. Arsenicum.

Order III. Metalla.
24. Hydrargyrum,
25. Molybdænum,
26. Stibium,
27. Zincum,
28. Vismuthum,
29. Cobaltum,
30. Stannum,
31. Plumbum,
32. Ferrum,
33. Cuprum,
34. Argentum,
35. Aurum.

Class III. FOSSILIA.

Order I. Petrificata.
36. Zoolithus,
37. Ornitholithus,
38. Amphibiolithus,
39. Ichthyolithus,
40. Entomolithus,
41. Helmintholithus,
42. Phytolithus,
43. Graptolithus.

Order II. Concreta.
44. Calculus,
45. Tartarus,
46. Aëtites,
47. Plumex,
48. Stalactites,
49. Tophus.

Order III. Terræ.
50. Ochra,
51. Arena,
52. Argilla,
53. Calx,
54. Humus.

In the mean time the discoveries of Henckel of Saxony, and his coadjutor Pott, had clearly demonstrated the important advantages which mineralogy may derive from chemistry. Much information was afforded by Henckel, particularly with regard to metals and their ores; but the system of external characters was entirely rejected by him as vague and unsatisfactory. More accurate chemical knowledge, however, marks the works of the celebrated Pott, justly styled the Klaproth of his age; and his unremitting attention in submitting to analytic examination the simple earths, enabled him to determine their characters with precision, and arrange them with accuracy. He divides them into four classes, viz. 1. Alkaline earth, or that which by burning forms quicklime, and produces effervescence when dissolved in acids. 2. Siliceous earth, insoluble in acids, but little altered by ignition. 3. Argillaceous earth, which, being viscid and ductile, is capable of being turned in a lathe, becomes hard in the fire, and is insoluble in acids. 4. Gypseous earth, which, by turning, is converted into gypsum which resists the acids; vitrifiable, but with difficulty.

Woltersdorf, the pupil of Pott, proposed a system embracing the whole mineral kingdom on a similar plan; but his chemical knowledge appears to have been inadequate to the task which he undertook, and his system is therefore imperfect. He comprehended the mineral kingdom under seven classes, in the following manner:—

1. Terræ.
Argillaceæ,
Alkalinæ.

2. Lapides.
Vitrescentes,
Argillacei,
Gypsei,
Alkalini.

3. Salia.
Acida,
Alkalina,
Intermedia.

4. Bitumina.
Fluida,
Solida.

5. Semimetalla.
Fluida,
Solida.

6. Metalla.
Nobilia,
Ignobilia.

7. Petrifacta.
Sanguineorum,
Insecta,
Testacea,
Vegetabilia,
Marina.

Nearly about the same time Wallerius published his Mineral uke indelt och Beskrifirt, in a second edition of which he thus completes his arrangement:—

Class I. Terræ.
Macræ,
Tenaces,
Minerales.

Class II. Lapides.
Calcarei,
Vitrescentes,
Fusibiles,
Apyri,
Saxa.

Class III. Mineræ.
Salia,
Sulphura,
Semimetalla,
Metalla.

Class IV. Concreta.
Pori,
Petrifacta,
Figurata,
Calculi.

Wallerius was the first by whom the principles on which systematic writers had hitherto arranged mineral substances were subjected to a strict examination. He rejected all characters derived from the value, use, or geognostic situation, and established it as a rule that the order and genera should be founded on chemical characters alone, while the species should be principally determined by their external character. The genera were distinguished by him with great precision, and augmented by the addition of some new ones. In these respects Waller holds a distinguished place among mineralogical writers, and his work may be advantageously consulted by the student of oryctognosy.

The appearance of Cronstedt of Stockholm, as a writer on mineralogy, forms an important epoch in the history of that science. In his work (Forsogtil Mineralogie, Stockholm 1758), he commences with some highly interesting and important observations on the gradual effects produced by fire and water on mineral substances, and on the slow, but unremitted changes they experience from various physical and chemical agents in the bowels of the earth. His system is throughout chemical, and the principles on which the classes and orders are established are still pretty generally acknowledged by systematic writers. He was the first who showed that petrifactions ought not to occupy a separate place in the system merely on account of their form, and also that the compound primitive rocks are not admissible into a system which professes to treat only of simple substances. For the first time, we find the then newly discovered platina, and also nickel, one of Cronstedt's own discoveries. The following brief sketch may serve to give the reader some idea of his method of arrangement:

Class I. Terræ.		Class II. Salia.	Class III. Phlogistica.	Class IV. Metalla.
1. Calcareæ	6. Fluores.	1. Acida.	or	1. Perfecta.
2. Siliceæ.	7. Asbestinæ.	2. Alkalina.	Bitumina.	2. Semimetalla.
3. Granatinæ	8. Zeolithicæ.		including	
4. Argillaceæ.	9. Magnesiæ.		Plumbago.	
5. Micaceæ.				

No work on mineralogy ever created a greater sensation than that of Cronstedt. In a short time after its appearance, it was translated into almost all the European languages; in all civilised countries the system was studied; and with some occasional deviations was adopted by most writers on minerals. Yet this system is not without great defects, and it is a matter of great difficulty to become acquainted with a mineral by consulting the description he gives of it. Cronstedt improved the classification of minerals, but the task of giving perfection to description, so indispensably necessary for the diagnosis of fossils, was reserved for his successor, whom it now becomes our duty to notice.

The celebrated Abraham Werner first published his classical work on the external character of minerals (Vonden äuffem Kennzeichen der Fossilien, Leipsic) in 1774; laid the foundation of a settled descriptive terminology that entirely banished the vague and arbitrary language then in use, and justly entitled its author to the title of the 'father of systematic mineralogy.' 'In this work,' says professor Jameson, 'he gave the first example of the true method of describing mineral species. In these descriptions, all the characters presented by the species-suite are detailed with a certain degree of minuteness, and in a determinate order; so that we have a complete picture of it, and are furnished with characters that distinguish it from all known species, and from every mineral that may hereafter be discovered.'

In 1780 Werner published a German translation of Cronstedt's mineralogy with copious notes, in which he gives an outline of his own ideas respecting a system of oryctognosy. All the other expositions of his system are by his pupils; they are of various merit, and some of them but ill-calculated to convey an adequate idea of its excellencies. Mr. Kirwan was the first who introduced it in this country; but for the most complete account of it we are indebted to professor Jameson of Edinburgh.

The fundamental principle laid down by Werner, in the systematic arrangement of fossile bodies, is the natural affinity, which he allows to be founded on the chemical mixture of their component parts. The Wernerian arrangement is, therefore, to a certain degree a mixed method. It is not supposed that an arrangement founded on these principles will always coincide with the experiments of the chemist; for it is only when chemical results agree with the natural alliances of the system that they are permitted to have a place in it, and in most cases where no satisfactory analysis existed of the mineral, the external characters alone decided its genus. In forming the metallic genera, says Werner, an attention to the constituent parts of minerals is unavoidable; for, were these genera to be established by external characters, independent of chemical analysis, the various species of ores, belonging to the same metal, would not always be collected into the same genus. Indeed several species of ores would undoubtedly be arranged among earthy minerals. Thus no one, relying on external characters only, would associate carbonate of lead with the other ores of that metal, nor even place it in any metallic genus. But in the natural history method of arrangement chemistry is entirely neglected, and different ores of the same metal are widely separated from each other. The reasons given for this alteration will be discussed anon.

Werner enumerates three different kinds of affinity in minerals, viz. the chemical, depending on a similarity of component parts, the mineralogical, consisting in the resemblance of their external characters, and the geological affinity

denoting a similarity of situation, relative age, &c.

The divisions and subdivisions introduced by Werner into the mineral kingdom are as follows; viz. class, order, genus, species, sub-species, kind. Certain species having a general resemblance have been collected into families, as the zeolite family, the felspar family. There are four classes, viz. earths, salts, inflammables, and metals. Each class is subdivided into genera. In most cases the genera are determined by the earth, salt, combustible, or metal, which is supposed to be either the predominant, or characteristic ingredient. It will be observed that a distinction is here made between the predominant and characteristic ingredient. It is indeed commonly the case, that the characteristic ingredient, or that which is most effective in producing the peculiar characters of the mineral, is also predominant in quantity. But there are some minerals which are not characterised by that ingredient which is present in the largest proportion. This distinction is undoubtedly important; and could we, in cases of minerals composed of several earths, estimate the relative energies as well as the relative quantities of the different ingredients, we might ascertain all that is essential to their true composition.

The following tabular sketch of the arrangement of the genera of Werner in 1789 will enable the reader to judge of the comparative merit of his system, and those of his predecessors:—

Wernerian System, 1789.

Class I.—EARTHS.

Order I.—Siliceous.

Genera.	Genera.
1. Lapis diaboli,	15. Quartz,
2. Diamond,	16. Hornstone,
3. Chrysoberyl,	17. Flint,
4. Zircon,	18. Chalcedony,
5. Hyacinth,	19. Lithoxylon,
6. Chrysolite,	20. Heliotrope,
7. Garnet,	21. Chrysoprase,
8. Ruby,	22. Schistous silex,
9. Sapphire,	23. Obsidian,
10. Topaz,	24. Cat's eye,
11. Emerald,	25. Phrenite,
12. Beryl,	26. Zeolite,
13. Schorl,	27. Lapis lazuli.
14. Lapis thumensis,	

Order II.—Argillaceous.

Genera.	Genera.
1. Pure argil,	15. Coticula,
2. Porcelain earth,	16. Tripoli,
3. Common clay,	17. Mica,
4. Jasper,	18. Chlorite,
5. Opal,	19. Chalkolite,
6. Pitchstone,	20. Hornblende,
7. Adamantine spar,	21. Wacke,
8. Felspar,	22. Basalt,
9. Clay state,	23. Lava,
10. Bituminous state,	24. Pumice,
11. Aluminous earth,	25. Green earth,
12. Aluminous schist,	26. Lithomarge,
13. Aluminous stone,	27. Mountain soap,
14. Nigrica,	28. Ochre.

Order III.—Talcs.

Genera.	Genera.
1. Steatite,	6. Serpentine,
2. Nephrite,	7. Talc,
3. Fuller's earth,	8. Asbestus,
4. Meerschaum,	9. Cyanite,
5. Bole.	10. Actinolite.

Order IV.—Calcareous.

Genera.	Genera.
1. Cactiform,	11. Bituminous marly schist,
2. Chalk,	12. Apatite,
3. Marble,	13. Boracite,
4. Compact marble,	14. Fluor,
5. Stalactite,	15. Gypsum,
6. Pisolite,	16. Selenite,
7. Slaty spar,	17. Witherite,
8. Magnesiac spar,	18. Ponderous spar
9. Swine-stone,	
10. Marl,	

Class II.—SALTS.

Order I.—Vitriolic.

Genera.	Genera.
1. Native vitriol,	4. Halotrichum,
2. Rock butter,	5. Native salamur
3. Alum,	

Order II.—Nitrous.

Genus.
Common native saltpetre.

Order III.—Muriatic.

Genera.	Genera.
Common rock salt,	Sal ammoniac

Order IV.—Borax.

Genus.
Native Borax.

Order V.—Alcaline.

Genus.
Natural mineral alkali.

Class III.—INFLAMMABLES.

Order I.—Bituminous.

Genera.	Genera.
1. Naphtha,	5. Petroleum,
2. Asphalt,	6. Spissexylon,
3. Coal,	7. Meliedite.
4. Amber,	

Order II.—Sulphureous.

Genera.
1. Common native sulphur,
2. Volcanic sulphur.

Order III.—Graphite.

Genus.
Native graphite.

Class IV.—METALS.

Genera.	Genera.
1. Platina.	Mercurial hepatic ore,
Native platina.	Cinnabar.
2. Gold.	4. Silver.
Native gold.	Native silver,
Nagiaker ore.	Nagiaker silver,
3. Mercury.	Arsenical silver,
Native mercury	Horn ore
Native amalgam,	Black silver ore
Mercurial horn ore,	Vitreous silver ore

Genera.	Genera.
Brittle silver ore	Yellow lead earth,
Red silver ore	Gray lead earth,
White silver ore.	Red lead earth,
5. Copper.	8. Tin.
Native copper,	Tin pyrites,
Copper glance,	Tinstone,
Variegated copper ore,	Cornish tin ore.
Copper pyrites,	9. Bismuth.
White copper ore,	Native bismuth,
Gray copper ore,	Bismuth glance,
Black copper,	Bismuth ochre.
Red copper ore,	10. Zinc.
Tile ore,	Blende,
Azure copper,	Calamine.
Malachite,	11. Antimony.
Copper green,	Native antimony,
Iron-shot copper green,	Gray antimony ore,
Olivine ore.	Red antimony ore,
6. Iron.	White antimony ore,
Native iron,	12. Manganese.
Iron pyrites,	Gray manganese ore,
Magnetical pyrites,	Black manganese ore,
Magnetical iron ore,	Red manganese ore.
Iron glance,	13. Nickel.
Red ironstone,	Copper nickel,
Brown ironstone,	Nickel ochre.
Sparry ironstone,	14. Cobalt.
Clay ironstone,	Gray cobalt ore,
Bog iron ore,	Glance cobalt,
Blue iron earth,	Black earthy cobalt,
Green iron earth,	Brown earthy cobalt,
Emery,	Yellow earthy cobalt,
Pitchblende.	Red cobalt.
7. Lead.	15. Arsenic.
Lead glance,	Native arsenic,
Blue lead ore,	Arsenical pyrites,
Brown lead ore,	Orpiment.
White lead ore,	16. Molybdena.
Green lead ore,	Molybdena.
Black lead ore,	17. Scheelium.
Red lead ore,	Tungsten,
Yellow lead ore,	Wolfram.

This system exhibits some curious anomalies. Thus sapphire is placed in the siliceous genus although composed of alumine nearly pure. But this stone is thus arranged in perfect conformity with the principles of the system; for a certain number of external characters, which siliceous minerals usually exhibit, being taken for the type of the genus, every mineral possessing these characters is to be arranged under this genus whether it contain any silex or not. Two other instances may be adduced of minerals arranged merely in consequence of their external characters in direct opposition to their true composition. One of these is the diamond, composed of pure carbon, and belonging to the class of combustibles; the other hallite or halyt from the Greek ἁλς, a salt, and which is in fact a genus of salts though arranged with the earths.

Such was the Wernerian arrangement of 1789. We shall now give, from professor Jameson's celebrated work on Mineralogy, his edition of Werner's system in 1815. For although other systems were in the mean time published by various authors, yet, in order to present the reader at one view with the whole of the Wernerian Mineralogy, we shall defer their present consideration, proceeding at once to *Werner's Mineral System in* 1815.

Class I.—EARTHY FOSSILS.

1. DIAMOND GENUS.

Diamond.

2. ZIRCON GENUS.

Zircon Family.

2. Zircon,	4. Cinnamon-stone
3. Hyacinth,	

3. FLINT GENUS.

Augite Family.

5. Chrysoberyl,	*c.* Conchoidal,
6. Chrysolite,	*d.* Common.
7. Olivine,	10. *Baikalite,*
8. Coccolite,	11. Sahlite,
9. Augite,	12. Diopside,
a. Granular,	13. *Fassaite.*
b. Foliated,	

Garnet Family.

14. Vesuvian,	21. Garnet,
15. Grossulare,	*a.* Precious,
16. Leucite,	*b.* Common.
17. *Pyrenite,*	22. Staurolite or grenatite,
18. Melanite,	
19. Allochroite,	23. Pyrope.
20. *Colophonite,*	

Ruby Family.

24. Automalite,	29. Corundum,
25. Ceylanite,	30. Diamond-spar,
26. Spinel,	———
27. Sapphire,	31. Topaz
28. Emery,	

Beryl Family.

32. Iolite,	*a.* Precious beryl,
33. Euclase,	*b.* Common,
34. Emerald,	36. Schorlous beryl,
35. Beryl,	37. Tourmaline.

Pistacite Family.

38. Lievrite,	42. Anthophylite,
39. Pistacite,	*a.* Radiated,
40. Diaspore,	*b.* Foliated,
41. Zoisite,	43. Axinite.

Quartz Family.

44. Quartz,	*b.* Carnelian,
a. Amethyst,	*α.* Common,
α. Common,	*β.* Fibrous,
β. Thick fibrous,	50. Hyalite,
b. Rock crystal,	51. Opal,
c. Milk quartz	*a.* Precious,
d. Common quartz,	*b.* Common opal,
e. Prase,	*c.* Semi-opal,
45. Iron-flint,	*d.* Wood-opal,
46. Hornstone,	52. Menilite,
a. Splintery,	*a.* Brown menilite
b. Conchoidal,	*b.* Gray menilite
c. Woodstone,	53. Jasper,
47. Flinty-slate,	*a.* Egyptian jasper
a. Common,	*α.* Red,
b. Lydian-stone,	*β.* Brown,
48. Flint,	*b.* Striped jasper,
49. Chalcedony,	*c.* Porcelain jasper,
a. Common,	*d.* Common jasper,

a. Conchoidal,
β. Earthy,
e. Opal jasper,
f. Agate jasper,
54. Heliotrope,
55. Chrysoprase,
56. Plasma,
57. Cat's eye,
58. *Faser Kiesel,*
59 Elaolite.

Pitchstone Family.

60. Obsidian,
61. Pitchstone,
62. Pearlstone,
63. Pumice.

Zeolite Family.

64. Phrenite,
a. Fibrous,
b. Foliated,
65. Natrolite,
66. Zeolite,
a. Mealy Zeolite,
b. Fibrous do.
c. Radiated zeolite,
d. Foliated do.
67. Ichthyophthalm,
68. Cubicite,
69. Cross-stone or crucite,
70. Laumonite,
71. Schmelzstein.

Azurestone Family

72. Azurestone,
73. Azurite.
74. Blue-spar.

Felspar Family.

75. Andalusite,
76. Felspar,
a. Adularia,
b. Labrador,
c. Glassy,
d. Common felspar,
α. Fresh,
β. Disintegrated,
e. Hollow spar,
f. Compact felspar,
α. Common,
β. Variolite,
77. Spodumene,
78. Scapolite,
a. Red scapolite,
b. Gray scapolite,
α. Radiated,
β. Foliated,
79. Meïonite,
80. Nepheline,
81. Ice-spar.

4. Clay Genus.

Clay Family.

82. Pure clay,
83. Porcelain earth,
84. Common clay,
a. Loam,
b. Potter's clay,
α. Earthy,
β. Slaty,
c. Variegated clay,
d. Slate clay,
85. Claystone,
86. Adhesive slate,
87. Polishing or polier state,
88. Tripoli,
89. Floatstone,
90. Alum-stone.

Clay-Slate Family.

91. Alum-slate,
a. Common,
b. Glossy,
92. Bituminous shale,
93. Drawing-slate,
94. Whet-slate,
95. Clay-slate.

Mica Family.

96. Lepidolite,
97. Mica.
98. Pinite,
99. Potstone,
100. Chlorite,
a. Chlorite earth.
b. Common chlorite,
c. Chlorite slate,
d. Foliated chlorite.

Trap Family.

101. *Paulite,*
102. Hornblende,
a. Common,
b. Basaltic,
c. Hornblende-slate,
103. Basalt,
104. Wacke,
105. Clinkstone,
106. Iron clay,

---

107. Lava.

Lithomarge Family.

108. Green earth,
109. Lithomarge,
a. Friable,
b. Indurated,
110. Rock-soap,
111. Umber,
112. Yellow earth.

5. Talc Genus.

Soapstone Family.

113. Native magnesia, or talc-earth,
114. Meerschaum,
115. Bole,
116. Fuller's earth,
117. Steatite,
118. Figurestone.

Talc Family.

119. Nephrite,
a. Common nephrite,
b. Axe-stone,
120. Serpentine,
a. Common,
b. Precious,
α. Conchoidal,
β. Splintery,
121. Schillerstone,
122. Talc,
a. Earthy,
b. Common,
c. Indurated,
123. Asbestus,
a. Rock-cork,
b. Amianthus,
c. Common asbestus,
d. Rock-wood.

Actynolite Family.

124. Kyanite,
125. Actynolite,
a. Asbestous,
b. Common,
c. Glassy,
d. Granular,
126. *Spreustein or chaff-stone.*
127. Tremolite,
a. Asbestous,
b. Common,
c. Glassy,
128. Sahlite,
129. *Rhætizite.*

6. Calcareous Genus.

A. *Carbonates.*

130. Rock milk,
131. Chalk,
132. Limestone,
a. Compact,
α. Common,
β. Roestone,
b. Foliated,
α. Granular,
β. Calcareous spar,
c. Fibrous,
α. Common,
β. Calc-sinter,
d. Pea-stone,
133. Calc-tuff,
134. Schaum earth, or foam earth,
135. Slate spar,
136. Brown spar,
a. Foliated,
b. Fibrous,
137. Schaalstone,
138. Dolomite,
139. Rhomb-spar,
140. *Anthracolite.*
141. Stinkstone,
142. Marl,
a. Marl earth,
b. Indurated marl,
143. Bituminous marl-slate,
144. Arragon,
a. Common,
b. Prismatic.

B. *Phosphates.*

145. Appatite,
146. Asparagus stone.

C. *Fluates.*

147. Fluor,
a. Compact,
b. Fluor spar.

D. *Sulphates*

148. Gypsum,
a. *Spumous gypsum.*
b. Earthy gypsum,
c. Compact gypsum,
d. Foliated gypsum,
e. Fibrous gypsum,
149. Selenite,
150. Muriacite.
a. Anhydrite,
b. *Gekröstein,*
c. Conchoïdal mur
d. Fibrous mur.
e. Compact mur.

E. *Borates*

151. Datolite,
152. Boracite,
153. Botryolite.

7. Baryte Genus.

154. Witherite,
155. Heavy spar,
a. Earthy heavy spar,
b. Compact heavy-spar,
c. Granular heavy-spar,
d. Curved lamellar heavy-spar,
e. Straight lamellar, heavy-spar,

a. Fresh,
β. Disintegrated,
f. Columnar spar,
g. Prismatic spar,
h. Bolognese, or Bolognian spar.

8. Strontian Genus.

156. Strontian,
a. Compact,
b. Radiated,
157. Celestine,
a. Fibrous,
b. Radiated,
c. Lamellar,
d. Prismatic.

9. Hallite Genus.

158. Cryolite.

Class II.—FOSSIL SALTS.

1. *Carbonates.*
159. Natural soda or natron.
2. *Nitrates.*
160. Natural nitre.
3. *Muriates.*
161. Natural rock-salt,
a. Stone-salt,
α. Foliated,
β. Fibrous.
b. Lake-salt,
162. Natural sal-ammoniac.
4. *Sulphates.*
163. Natural vitriol,
164. Hair-salt,
165. Rock-butter,
166. Natural Epsom-salt,
167. Natural Glauber-salt.

Class III.—INFLAMMABLE FOSSILS.

1. Sulphur Genus.

168. Natural sulphur,
a. Crystallised,
b. Common,
α. Earthy,
β. Conchoidal,
c. Mealy,
d. Volcanic.

2. Bituminous Genus.

169. Mineral or fossil oil,
170. Mineral pitch,
a. Elastic,
b. Earthy,
c. Slaggy,
171. Brown coal,
a. Bituminous wood,
b. Earth coal,
c. Alum earth,
d. *Paper coal,*
e. Common brown, coal,
f. Moor coal,
172. Black coal.
a. Pitch coal,
b. Columnar coal,
c. Slate coal,
d. Cannel coal,
e. Foliated coal,
f. Coarse coal.

3. Graphite Genus.

173. Glance-coal,
a. Conchoidal,
b. Slaty,
174. Graphite,
a. Scaly,
b. Compact,
175. Mineral charcoal.

4. Resin Genus.

176. Amber,
a. White,
b. Yellow,
177. Honey stone.

Class IV.—METALLIC FOSSILS.

1. Platina Genus.

178. Native Platina.

2. Gold Genus.

179. Native gold,
a. Gold yellow,
b. Brass yellow,
c. Grayish yellow.

3. Mercury Genus.

180. Native mercury,
181. Natural amalgam,
a. Semi-fluid,
b. Solid,
182. Mercurial horn-ore,
183. Mercurial liver-ore,
a. Compact,
b. Slaty,
184. Cinnabar,
a. Dark red,
b Light red

4. Silver Genus.

185. Native silver,
a. Common,
b. Auriferous,
186. Antimonial silver,
187. Arsenical silver,
188. *Molybdena silver,*
189. Corneous silver-ore, or horn-ore,
190. Silver-black,
191. Silver-glance,
192. Brittle silver-glance,
193. Red silver-ore,
a. Dark,
b. Light,
194. White silver-ore.

5. Copper Genus.

195. Native copper,

Family of Copper Sulphurets.
196. Copper-glance,
a. Compact,
b. Foliated,
197. Variegated copper-ore,
198. Copper-pyrites,
199. White copper-ore.
200. Gray copper-ore,
201. Black copper-ore,

202. Red copper-ore,
a. Compact,
b. Foliated,
c. Capillary,
203. Tile-ore,
a. Earthy,
b. Indurated,
204. Azure copper-ore,
a. Earthy,
b. Indurated or radiated,
205. *Velvet copper-ore,*
206. Malachite,
a. Fibrous,
b. Compact,
207. Copper-green,
208. Ironshot copper-green,
a. Earth,
b. Slaggy,
209. Emerald copper-ore,
210. Copper mica,
211. Lenticular-ore
212. Oliven-ore,
213. Muriate of copper,
214. Phosphate of copper.

6. Iron Genus.

215. Native iron,
216. Iron-pyrites.
a. Common pyrites,
b. Radiated pyrites,
c. Liver or hepatic pyrites,
d. Cock's-comb pyrites,
e. Cellular pyrites,
217. Capillary pyrites,
218. Magnetic pyrites,
219. Magnetic ironstone,
a. Common,
b. Iron-sand,
220. *Chrome-ironstone,*
221. *Menac ironstone,*
222. Iron-glance,
a. Common,
α. Compact,
β. Foliated,
b. Iron-mica,
223. Red ironstone,
a. Red iron-froth,
b. Ochry red ironstone,
c. Compact,
d. Red hæmatite,
224. Brown ironstone,
a. Brown iron froth,
b. Ochry brown ironstone,
c. Compact,
d. Brown hæmatite,
225. Sparry ironstone,
226. Black ironstone,
a. Compact,
b. Black hæmatite,
227. Clay-ironstone,
a. Reddle,
b. Columnar clay-ironstone,
c. Lenticular clay-ironstone,
d. Jaspery clay-ironstone,
e. Common clay-ironstone,
f. Reniform clay-ironstone,
g. Pea-ore, or pisiform ironstone,
228. Bog iron-ore,
a. Morass-ore,
b. Swamp-ore,
c. Meadow-ore,
229. Blue iron-earth,
230. Pitchy iron-ore,
231. Green iron-earth,
232. Cube-ore,
233. Gadolinite.

7. Lead Genus.

234. Galena, or Lead-glance,
  a. Common,
  b. *Disintegrated*,
  c. Compact,
235. Blue lead-ore,
236. Brown lead-ore,
237. Black lead-ore,
238. White lead-ore,
239. Green lead-ore,
240. Red lead-ore,
241. Yellow lead-ore,
242. Lead-vitriol,
243. Earthy lead-ore, or lead earth,
  a. Coherent,
  b. Friable.

8. Tin Genus.

244. Tin pyrites,
255. Tinstone,
246. Cornish tin-ore.

9. Bismuth Genus.

247. Native bismuth,
248. Bismuth-glance,
249. Bismuth-ochre,
250. *Arsenical bismuth-ore*.

10. Zinc Genus.

251. Blende,
  a. Yellow,
  b. Brown,
    α. Foliated,
    β. Fibrous,
    γ. Radiated,
  c. Black,
252. Calamine.

11. Antimony Genus.

253. Native antimony,
254. Gray antimony-ore,
  a. Compact,
  b. Foliated,
  c. Radiated,
  d. Plumose,
255. Black antimony-ore,
256. Red antimony-ore,
257. White antimony-ore,
258. Antimony-ochre.

12. Sylvan Genus.

259. Native sylvan,
260. Graphic-ore,
261. White sylvan-ore,
262. Nagyag-ore.

13. Manganese Genus.

263. Gray manganese-ore,
  a. Radiated,
  b. Foliated,
  c. Compact,
  d. Earthy,
264. Black manganese-ore,
265. *Piedmontese manganese-ore*,
266. Red manganese ore,
267. *Manganese-spar*.

14. Nickel Genus.

268. Copper-nickel,
269. *Capillary-pyrites*,
270. Nickel-ochre.

15. Cobalt Genus.

Family of Speiss Cobalt.

271. White cobalt-ore,
272. Gray cobalt-ore,
273. Glance-cobalt.

Family of Cobalt-Ochre.

274. Black cobalt-ochre,
  a. Earthy,
  b. Indurated,
275. Brown cobalt-ochre,
276. Yellow cobalt-ochre,
277. Red cobalt-ochre,
  a. Cobalt-crust,
  b. Cobalt-bloom.

16. Arsenic Genus.

278. Native arsenic,
279. Arsenic pyrites,
  a. Common,
  b. Argentiferous,
280. Orpiment,
  a. Yellow,
  b. Red,
281. Arsenic bloom.

17. Molybdena Genus.

282. Molybdena.

18. Sheele Genus.

283. Tungsten,
284. Wolfram.

19. Menachine Genus.

285. Menachan,
286. Octahedrite,
287. Rutile,
288. Nigrine,
289. Iserine,
290. Brown menachine-ore,
291. Yellow menachine-ore.

20. Uran Genus.

292. Pitch-ore,
293. Uran-mica,
294. Uran-ochre.

21. Chrome Genus.

295. Acicular-ore,
296. Chrome-ochre.

22. Cerium Genus.

297. Cerium-stone.

Having given this general idea of Werner's system, we cannot proceed to notice that of Bergman without making honorable mention of the celebrated Romé d l'Isle, whose indefatigable researches so eminently contributed to the progress of the science, and whose Christallographie ou Description des formes propres à tous les corps du regne Minerale, published in 1783, has been deservedly characterised as the result of labors immense in their extent, almost entirely novel in their object, and of the highest importance on account of their utility.

In this elaborate performance the author gives a description of the forms proper to every substance of the mineral kingdom, in a saline, stony, and metallic combination; with figures of all the known crystals, arranged according to the number and disposition of their angles. He asserts, which is generally admitted, that every species in the mineral kingdom always takes a polyhedral primitive form, which is regular, constant, and peculiar to itself. See Crystallography.

The celebrated Bergman, who succeeded Wallerius in the mineralogical chair of Upsal, also published a sketch of a mineral system in his Physical Description of the Earth, 1784. He divided the mineral kingdom into four classes in the following manner:—

Class I. Salia.

Orders.

1. Acida.
2. Alkalina.
3. Neutralia.
4. Terrestria.
5. Metallina.
6. Tripliciter combinata.

Class II. Terræ.

Orders.

1. Ponderosæ.
2. Calx.
3. Magnesiæ.
4. Argillaceæ.
5. Siliciæ.

Class III. Bitumina.

Orders.

1. Bitumen.
2. Petroleum.
3. Adamas.

Class IV. Metalla.

Including all the metals in one order.

The next writer of importance is the celebrated Kirwan of Dublin, the founder of the Dublin Mineralogical Society, and the first who introduced the Wernerian system to notice in this country. His Elements of Mineralogy, which appeared in 1784, may be considered as the first work of importance on the subject published in

Great Britain, and principally excited that attention to the science which it has since so deservedly enjoyed. The following extract will exhibit the most prominent features of his mineralogical arrangement :—

The classification of earths, says Mr. Kirwan, and stones, consists in their arrangement in a certain order relatively to each other.

Order, when not arbitrary, necessarily supposes both distinction and resemblance. Without distinction all the bodies to be arranged would be equally entitled to the same place in the series. Without resemblance no reason could be assigned why a body should occupy one particular place rather than another place, there being no relation to connect it with the preceding.

Hence it follows that those bodies which resemble each other most should be grouped together; and, consequently, that there should be as many heads of general division as there are general grounds of resemblance.

If it be asked whence this resemblance should be taken; whether from the external or internal characters? I answer, it should be taken from both, it being the result of the joint consideration of both.

Now, upon examining the totality of homogeneous earths and stones, it will be found that those resemble each other most that contain the largest proportion of the same simple earth, or most of the characterising properties of the same simple earth; and, as there are nine simple earths, it follows that there must be nine genera, or primary divisions of homogeneous earths and stones. In the same manner, under each head or genus, we may consider those substances as specifically different that resemble each other least, or that differ in some important property relatively to human uses; for systems being fabricated to help the memory, by pointing out the most important distinctions, and none being more so than those that are applicable to human uses, should never lose sight of their primary end and designation.

Hence, 1. The generic earths, combined with an acid, are specifically different from those that are not. 2. The same generic earth, combined with different acids, forms different species. 3. The same generic earth, combined with a notable proportion of one or more of the other earths, forms a different species from the same generic earth, either uncombined or combined with a less important proportion of other earths. I call a proportion, continues this writer, notable or important when it introduces a considerable alteration in the external or internal characters of the compound. Thus such a proportion as induces a considerable change in the specific gravity, or in the fusibility of any substance, is notable or important; so in the calcareous genus such a proportion of foreign earth, or earths, as would prevent it from burning to lime, is certainly of importance, and the distinction grounded in nature: so proportions that alter the fusibility of substances, with respect to the degree at which they are fusible, are certainly notable, and a good foundation for specific distinctions. But varieties of proportion, or even of ingredients, that produce no notable change, either in the internal or external properties of a compound, make no alteration in the species; and in fact there are scarcely any earths or stones that have, strictly speaking, the same proportion of ingredients. Traps or basalts, and zeolytes, vary considerably. 4. Any earth which forms less than one-twentieth of a compound, is almost always of little importance. 5. Water forms an important part of any compound when it exceeds one twenty-fifth of the whole. 6. Calces of iron influence in some measure the properties of a compound, when they exceed one thirty-third of the whole. If they are themselves magnetic, they communicate that property to compounds of which they form above one-tenth.

Species are further divisible from some particular points of agreement into families, or classes and families; sometimes it is necessary to form distinctions where specific characters are not decided; in which case I distribute the classes into tribes and families, as will be seen in the sequel. The minuter diversifications are called varieties. The term specimen corresponds with that of individual in the animal kingdom.

In this system Mr. Kirwan adopted the classes of Werner, but varied the orders and distribution of the genera as follows :—

Class I.—EARTHS.

This class includes the orders Calcareous, Barytic, Muriatic, Argillaceous, Siliceous, Aggregate, and Mixed Earth, and each order the following genera :—

Order I. Calcareous.

Genera.	Genera.
Native lime,	Marlite,
Aerated calx,	Pyritaceous limestone
Agaric mineral chalk,	Argentine,
Arenaceous limestone,	Sidero-calcite,
Testaceous tufa,	Ferro-calcite,
Compact limestone,	Elastic marble,
Swinestone,	Gypsum,
Oviform,	Fluor,
Baryto-calcite,	Phosphorite,
Muri-calcite,	Tungsten.
Marl,	

Order II. Barytic.

Genera.	Genera.
Baroselenite,	Liver-stone.

Order III. Muriatic.

Genera.	Genera.
Kiffekil,	Asbestus,
Martial muriatic spar,	Amianth,
Calci-murite,	Mountain-cork,
Argillo-murite,	Amianthinite,
Chlorite,	Asbestinite,
Talcite,	Actinolite,
Talc,	Jade,
Steatite,	Boracite,
Pot-stone,	Baikalite.
Serpentine,	

Order IV. Argillaceous.

Genera.	Genora.
Native argill,	Potter's clay,
Porcelain clay,	Indurated clay,

Schistose,	Micarelli,
Shale,	Hornblend,
Fuller's earth,	Basaltine,
Lithomarge,	Labrador hornblend,
Bole,	Schiller spar,
Argillaceous marl,	Schistose hornblend,
Colored chalk,	Wacken,
Green earth,	Muller,
Umber,	Kragg,
Tripoli,	Trapp,
Phospholite,	Basalt,
Lepidolite,	Calp,
Sapparre,	Argillite,
Mica,	Novaculite.

Order V. SILICEOUS.

Genera.	Genera.
Quartz,	Chalcedony,
Amethyst,	Cat's eye,
Emerald,	Flint,
Beryl,	Hornstone,
Prase,	Schisthose hornstone,
Oriental ruby,	Siliceous schist,
Spinel,	Basamite,
Accidental ruby,	Hornslate,
Hyacinth,	Japper,
Garnet,	Egyptian pebble,
Chrysoberyl,	Sinople,
Chrysolite,	Porcellanite,
Olivin,	Heliotrope,
Obsidian,	Woodstone,
Shorl,	Elastic quartz,
Tourmalin,	Felspar,
Thumerstone,	Labrador-stone,
Phrenite,	Petrile,
Ædilite,	Felzite,
Zeolite,	Argentine felspar,
Stauwhite,	Red-stone,
Kubellite,	Siliceous spar,
Opal,	Agate,
Semiopal,	Stronthian,
Pitchstone,	Jargon,
Hydrophanes,	Sidneia,
Hyalite,	Adamantine earth.

Order VI. AGGREGATE.

Genera.	Genera.
Granite (quartz, felspar, mica).	Granilite (aggregates of four).
Sienite (quartz, felspar, hornblend, or quartz,felspar,hornblend, mica).	Gneiss,
Granitine triplets, formed of any triple aggregation.	Schistose, mica (quartz and mica).
Norka, or murker (quartz, mica, garnet).	Porphyry,
Grunsten (hornblend and mica, hornblend and felspar.	Amygdaloid,
Granitell (duplicates), Stellstein (quartz and mica).	Pudding-stone,
Rapikivi (felspar and mica).	Sand-stones,
	Rubble-stone,
	Breccias,
	Nagel fluhe,
	Anomalous grits,
	Horn rock,
	Serpentine rock,
	Topaz rock,
	Garnet rock,
	Steatitic rock
	Variolites.

Order VII. MIXED EARTHS.

Genera.	Genera.
Lime-stones,	Spars,
Calces of iron,	Marls,
Gypsum,	Trap,
Potstone,	Argillite,
Steatites	Hornblend-slate, &c.
Calciferous asbestinite,	Iron shot quartz,
Serpentine,	Earthy quartz, &c.

Appendix I.
Diamond.

Appendix II.

Genera.	Genera.
Lavas,	Pumice,
Enamels,	Zeolites,
Terras,	Traps,
Tufas,	and
Piperino,	Basalts.

Class II.—SALTS.

This class includes the orders Acid, Alkaline, Neutral; and, under each, the following genera:—

Order I. ACID.

Genera.	Genera.
Carbonic,	Phosphoric,
Vitriolic,	Arsenical,
Sulphureous,	Boracic,
Nitrous,	Molybdenous,
Muriatic,	Tungstenic.
Sparry,	Succinous.

Order II. ALKALINE.

Genera.	Genera.
Vegetable,	Volatile alcalies.
Mineral,	

Order III. NEUTRAL.

Genera.	Genera.
Tartar-vitriolate,	Nitrated magnesia,
Glauber's salt,	Salt of Sylvius,
Vitriol-ammoniac,	Common salt,
Epsom-salt,	Sal ammoniac,
Alum,	Muriated barytes,
Aluminous ores,	——— calx,
Vitriol of iron, copper, &c.	——— magnesia,
	——— argill,
Copper and zinc,	——— iron,
Nitre,	——— copper,
Nitrous ammoniac,	——— manganese,
Nitrated soda,	Borax,
——— calx,	Tincal.

Class III. INFLAMMABLES.

This class comprehends the orders Aërial, Bituminous, Carbonaceous, and Vegeto-bituminous, and under each the following genera:—

Order I. AERIAL.

Genera.	Genera.
Inflammable,	Hepatic.

Order II. BITUMINOUS.

Genera.	Genera.
Napththa,	Maltha,
Petiol,	Mineral tallow,
Mineral tar,	Mineral caoutchou.
Mineral pitch,	

Order III. CARBONACEOUS.

Genera.	Genera.
Coal,	Carbonated wood,
Plumbago,	Turf and peat.

Order IV VEGETO-BITUMINOUS.

Genera.	Genera.
Jet,	Copal,
Amber,	Honey-stone,
Ambergris,	Sulphur.

Class IV.—METALS.

This class comprehends the following metals under the three orders, Perfect, Imperfect, Semimetals.

Order I.	PERFECT.
Genera.	Genera.
Platinum,	Silver,
Gold,	Quicksilver.

Order II.	IMPERFECT.
Genera.	Genera.
Copper,	Lead,
Iron,	Tin.

Order III.	SEMIMETALS.
Genera.	Genera.
Zinc,	Uranite,
Antimony,	Tungstenite,
Arsenic,	Molybdænite,
Bismuth,	Sylvanite,
Cobalt,	Menachanite,
Nickel,	Titanite.
Manganese,	

Mr. Kirwan's works on mineralogy were long considered standard authorities; his Elements were translated into several languages, and his system was received with considerable applause even by the continental mineralogists. The clearness of his descriptions, and the accuracy of his experiments, entitle him to the warmest gratitude of the student; who may obtain much valuable information by a perusal of his works.

Although in this historical sketch we have rather endeavoured to present the reader with an account of mineralogical arrangements than of discoveries in the science of mineralogy, yet we must not omit to notice the celebrated Klaproth, whose works have perhaps contributed more to the chemical knowledge of minerals than those of any other writer. Were we to attempt to exhibit the chief merit of Klaproth, as a chemist, we should place it not so much in the discovery of new metals and earths as in the invention of a more exact and more perfect method of analysis than was previously attempted. The former kind of merit is more adapted to draw the attention of the public at large; but the latter is of infinitely greater consequence to science. We can here only notice the two principal methods of analysis with which he enriched the science of experimental chemistry.

The first of these was the complete resolution of the hardest minerals, by means of fluid caustic alkali, instead of the former treatment with dry caustic alkali, which had introduced the use of silver crucibles and saucers. The complete resolution of the hardest stones, by this method of analysis, has enabled us to ascertain, with extreme accuracy, the quantity of earths, oxides, metals, and even of acids, which minerals contain. Exact analyses of this kind remain sure for ever, and are of importance to the science, independently of any discoveries which may be made respecting the particular nature of the substances mentioned. As, for instance, the capability of being decomposed, which was afterwards discovered to belong to the earths, makes not one cypher incorrect or superfluous in such analysis. The advantage of this method is particularly evident in the decomposition of corundum or diamond-spar. As Klaproth first attempted the analysis of these bodies, by the old methods of decomposition, he found a considerable remainder of matter unaccounted for. On the suspicion, which he then expressed, that this remainder might perhaps be a new, and yet undiscovered earth, many compilers of school books were in a hurry to admit the earth of corundum into the list of the simple earths. But when Klaproth repeated the analysis, by means of the liquid alkali, he found that this substance was one of the many compositions of siliceous and argillaceous earths which had not previously been known, and which in former analyses had sometimes been referred to the one kind of earth, and at other times to the other. In the same manner, the chemists of England gave an account of a species of sand, which had been brought from New Holland, as a new earth; but Klaproth showed, by his new method of analysis, that this body also, which had already been introduced into introductory treatises, under the name of the Austral Earth, was nothing but an intimate mixture of siliceous and argillaceous earth. Indeed, the first analyses that can be considered as certain are those which have been undertaken on this plan. Hence, by this discovery, almost all the more early analyses have lost their value.

In the numerous exact analyses which Klaproth conducted according to this method, there was almost always discovered at last to be a small loss, that is to say, the weight of all the single component parts was ascertained to be somewhat less than the weight of the mineral which had been analysed. He in every case stated this loss with great precision, and by this undeviating regard to truth, obviously procured for the results of his labors a much greater certainty than if he had permitted himself, as he might easily have done, to conceal this loss under inconsiderable changes in the decimal figures. He also never gave his results, as he likewise easily might have done, in a great crowd of decimals, by which means the appearance of much exactness is sometimes gained, but he gave only as many cyphers as were pure. As long as the loss amounted only to a few thousand parts of the whole, it might easily be referred to those small mistakes which in every course of experiments are unavoidable, from the limited nature of our senses and instruments. But in some analyses, as for instance in that of Felspar, a loss of some hundred parts was discovered. Such a loss, considering the care with which Klaproth labored, could only arise from some of the constituent parts having entirely escaped observation during this method of resolution. Convinced that this could be neither an earth nor a metal, nor an acid, nor water, nor any other volatile matter, he at last began to suspect that perhaps many minerals might contain a hitherto unsuspected quantity of fixed alkali, which could not be discovered by the method of analyses by means of these alkalies. This consideration led to Klaproth's second great invention, viz. the method of analysis by means of Barytes, although, as was formerly remarked, the excellent Rose had a considerable part in this invention.

Having thus given as detailed a history as our limits would permit of the ancient systems, we proceed to

PART II.

AN ANALYSIS AND COMPARISON OF THE MODERN SYSTEMS OF MINERALOGY.

Of these, the first is that of the abbé Haüy, whose labors in CRYSTALLOGRAPHY have occupied our attention in that article. We have there given a succinct account of his Theory of the Structure of Crystals, to which we refer the reader. Several memoirs of Haüy on this subject were followed in 1801 by that celebrated professor's great work, entitled Traité de Mineralogie, in which his crystallographic theory is made subservient to the classification of minerals. He here defines the mineralogical species to be a collection of bodies whose integrant parts are alike, and composed of the same principles united in the same proportion. According to his idea of the subject, minerals have both a geometrical and chemical limit, the former consisting in the invariable form of the molecule, the latter in the composition of the same molecule. Haüy prefers making use of the geometrical limit for determining the species, not only because minerals being in general more or less mixed with heterogeneous matter, so often that the best chemical analysis is but imperfect, whereas mechanical division invariably furnishes the same form of the molecule, but principally because the geometrical limit is far more obvious and palpable, since to obtain it nothing more is often necessary than to divide the substance mechanically.

Notwithstanding the great reliance which M. Haüy places on the form of the integrant particle, he has remarked, in his Tableau Comparatif, that he does not consider a knowledge of the form of the integrant particle indispensable to the admission of a mineral to the rank of a distinct species, provided its composition be well ascertained, and found to be different from that of any known species. And it was under these circumstances that he first introduced the chromate of iron, as a distinct species. It appears that M. Haüy's first object in forming his system of crystallography was to unite different crystallised varieties of the same species about one common point, as a nucleus or primitive form; and he was thus almost necessarily led to form an arrangement of crystallised minerals only. But, however perfect this system may be in regard to the laws by which various secondary forms are derived from the same primitive form, it is not, even by its celebrated author, supposed equally competent to establish a mineralogical method. As therefore the character of the integrant molecule is not sufficient, the abbé adds to it another chemical or physical; thus, for instance, the property of dissolving in water superadded to the cubic form, determines muriate of soda (common salt); but, if the same form is united to the property of becoming electric by heat, we have borate of magnesia or common boracite.

The following is Haüy's distribution, taken principally from his Tableau Comparatif des Resultats de la Crystallographie, et de l'Analyse Chimique, Paris, 1809. The names in parentheses are those of the Wernerian school.

Class I.—ACIDIFEROUS SUBSTANCES.

Order 1.—*Disengaged acidiferous substances.*

1st. genus. Sulphuric acid.
2d. genus. Boracic acid.

Order II.—*Earthy acidiferous substances.*

A. with simple base :—
1st genus. Chaux (lime).
1, 3. Ch. carbonatée (comprising all the Wernerian species of carbonates of lime, with the exception of the following species).
4. Arragonite.
5. Ch. phosphatée (apatite).
6. Ch. fluatée (fluor).
7. Ch. sulfatée (gypsum and selenite).
8. Ch. anhydro-sulfatée (anhydrite).
9. Ch. nitratée.
10. Ch. arseniatée (arsenic bloom; pharmacolite, Klapr.)
2d genus. Baryte.
11. Baryte sulfatée (barytes or heavy spar).
12. B. carbonatée (witherite).
3d genus. Strontian.
13. S. sulfatée (celestine).
14. S. carbonatée (strontian).
4th genus. Magnesie.
15. M. sulfatée (natural Epsom or bitter salt).
16. M. boratée (boracite).
17. M. carbonatée (native magnesia or talc earth).
5th genus. Lime and silica.
18. Chaux boratée siliceuse (datholite).
6th genus. Silica and alumine.
19. Silice fluatée alumineuse (topaz and pycnite, or short beryl).

Order III.—*Acidiferous alkaline substances.*

1st genus. Potasse.
20. P. nitratée (natural nitre).
2d genus. Soude.
21. S. sulfatée (natural Glauber salt).
22. S. muriatée (rock-salt).
23. S. boratée (tinkal, K.)
24. S. carbonatée (natural soda or natron).
3d genus. Ammoniaque.
25. A. sulfatée (mascagnin, K.)
26. A. muriatée (natural sal ammoniac).

Order IV.—*Acidiferous alkaline earthy substances.*

27. Alumine sulfatée alcaline (alum).
Appendix.
28. Alumine fluatée alcaline (kryolite).
29. Glauberite.

Class II.—EARTHY SUBSTANCES.

(No subdivision into orders).

30. Quarz (the whole of Werner's quarz family, comprising fourteen of his species).
31. Zircon (zircon and hyacinth).
32. Corindon (corundum, sapphire, diamond, spar, emery).
33. Cymophane (chrysoberyl),
34. Spinelle (spinel, ceylanit).
35. Emeraude (emerald, beryl).
36. Euclase

37. Grenat (garnet, melanite).
38. Amphigene (leucite).
39. Idocrase (Vesuvian).
40. Meïonite.
41. Feld-spath (feldspar).
42. Apophyllite (fish-eye stone or ichthyophthalmite).
43. Triphane (spodumen).
44. Axinite.
45. Tourmaline (shorl).
46. Amphibole (all the sub-species of hornblende, except Labrador hornblende, actinote, augite, and tremolite partly.
47. Pyroxène (augite, sahlite).
48. Yenite.
49. Staurotide (staurolite).
50. Epidote (pistazite, zoisit).
51. Hypersthène (Labrador hornblende).
52. Wernerite (arktizit).
53. Paranthine (scapolite).
54. Diallage (variety of arctinote, schillerstein).
55. Gadolinite.
56. Lazulite (azur-stone).
57. Mesotype fibrous and mealy zeolite, nadelstein.
58. Stilbite (radiated and foliated zeolite).
59. Laumonite (lomonit).
60. Prehnite.
61. Chabasie (schabasit).
62. Analcime (kubizit).
63. Nepheline (nephelin; sommit K.)
64. Harmotome (cross-stone).
65. Peridot (chrysolite, olivine).
66. Mica (glimmer or mica).
67. Pinite.
68. Disthène (cyanite).
69. Dipyre (schmelz-stein; dipyr, K.)
70. Asbeste.
71. Talc.
72. Marle (hollow spar; chiastolite, K.)

To this class are appended the following substances, the characters of which are not sufficiently well understood to assign them their respective places in the system:—

Allochroite (splintery garnet, K.)
Alumine, pure (pure clay).
Amianthoïde.
Antophillit, Schum. and Wern.
Aplome.
Bergmannit, Schum.
Diaspore.
Feldspath apyre, H. (andalusit).
Feldspath bleu (variety of compact feldspar).
Fibrolite, Bourn.
Gabbronite, Schum.
Jade (common nephrite, axe-stone).
Jolithe, W. and K.
Kaneel or cinnamon stone, W.
Lazuli, W.
Latialite (hauyne).
Lepidolite, W.
Melilite, Fleuriau.
Natrolite, W.
Pseudo-sommit; Fleur de B.
Spath en tables (schaalstein).
Spinellane.
Spinelle zincifère? (automalite).
Spinthère, H.
Talc? granuleux (earthy talc), and
T. glaphique (bildstein; agalmatolite, K.)

Class III.—COMBUSTIBLE NOT METALLIC SUBSTANCES.

Order 1.—*Simple.*

73. Soufre (sulphur).
74. Diamant (diamond).
75. Anthracite (kohlenblende, glanz-kohle).

Order II.—*Compounds.*

76. Graphite.
77. Bitume (mineral oil; mineral pitch).
78. Houille (black coal).
79. Jayet (pitch coal).
80. Succin (amber).
81. Mellite (honey-stone).

Class IV.—METALLIC SUBSTANCES.

Order 1.—*Not immediately oxidable except by a very high degree of heat, and immediately reducible.*

1st genus. Platina.
82. P. natif ferrifère (native platina).
2d. genus.
83. O. natif. (native gold).
3d. genus. Argent.
84. A. natif (native silver).
85. A. antimonial (antimonial silver); as appendix to it,
A. antimonial ferro-arsénifère (arsenical silver).
86. A. sulfuré (vitreous silver-ore).
87. A. antimonié sulfuré (red-silver-ore); and, as appendix to it,
A. antimonié sulfuré noir (brittle vitreous silver).
88. A. carbonaté.
89. A. muriaté (horn-ore or horn-silver).

Order II.—*Immediately oxidable and reducible: Mercure.*

90. M. natif (native mercury).
91. M. argental (native amalgam).
92. M. sulphuré (cinnabar); and, as appendix,
Mercure sulfuré bituminifère (mercurial liver-ore).
93. Mercure muriaté (mercurial horn-ore).

Order III.—*Oxidable, but not immediately reducible.*

a, sensibly ductile.
1st genus. Plomb.
94. P. natif volcanique.
95. P. sulfuré (galena); by way of appendix,
P. sulf. antimonifère, and
P. sulf. antimonifère et argentifère (weissgultig-erz).
96. P. oxydé rouge.
97. P. arseniaté (flokken-erz, K).
98. P. chromaté (red lead-ore).
99. P. carbonaté (white lead-ore); and, as appendix,
P. carb. noir (black lead-ore, lead earth; and
P. carb. cuprifère.
100. P. phosphaté (brown and green lead-ore).
101. P. molybdaté (yellow lead-ore).
102. P. sulfaté (natural lead vitriol).
2d genus. Nickel.

103. N. natif (capillary iron pyrites).
104. N. arsenical (copper nickel).
105. N. oxydé (nickle ochre).
3d genus. Cuivre.
106. C. natif (native copper).
107. C. pyriteux (copper pyrites); and, as appendix,
C. pyr. hépatique (variegated copper-ore).
108. C. gris (gray copper ore).
109. C. sulfuré (vitreous copper ore).
110. C. oxydulé (red copper ore and tile ore).
111. C. muriaté (saltz-kupfer).
112. C. carbonaté bleu (copper azur).
113. C. carb. vert (malachite; copper green).
114. C. arseniaté (lenticular copper ore; olive ore); as appendix,
C. arsen. ferrifère (cupreous arseniate of iron, Bourn).
115. C. dioptase (copper emerald).
116. C. phosphaté.
117. C. sulfaté (copper vitriol, K).
4th genus. Fer.
118. Fer natif (native iron).
119. F. oxydulé (magnetic iron stone); and, by way of appendix,
F. oxydulé granuliforme (iron-sand).
120. F. oligiste (specular iron, iron mica, red iron froth, red hematite; compact red iron-stone, columnar clay iron-stone).
121. F. arsenical (common arsenical pyrites); and, as appendix,
F. arsenical argentifere (weiss-ertz, W. noble arsenical pyrites, K).
122. F. sulfuré (common pyrites); and, as appendix,
F. sulfuré épigène (leberkies, but not of Werner), and
F. sulfuré ferrifere (magnetical pyrites).
123. F. oxydé (brown hæmatite; reniform and lenticular clay iron-stone; green iron-earth); and, as appendix,
F. oxydé résinite (eisenpech-erz, or pitchy iron-ore); also part of F. oxydé carbonaté (sparry iron-stone).
124. F. phosphaté (blue iron earth).
125. F. chromaté (eisen-chrom, K.)
126. F. arseniaté (cube ore).
127. F. sulfaté (native vitriol).
5th genus. Etain.
128. E. oxydé (tin-stone); and, as appendix,
E. oxydé concrétionné (Cornish tin ore, or wood tin).
129. E. sulfuré (tin pyrites).
6th genus. Zinc.
130. Z. oxydé (calamine).
131. Z. carbonaté.
132. Z. sulfuré (blende).
133. Z. sulfaté (zinc vitriol, K).
b, not ductile.
7th genus. Bismuth.
134. B. natif (native bismuth).
135. B. sulfuré (bismuth glance); and, as appendix,
B. sulf. plumbo-cuprifère (needle ore).
136. B. oxidé (bismuth ochre).
8th genus. Cobalt.
137. C. arsenical (white and gray cobalt-ore).
138. C. gris (cobalt glance).
139. C. oxidé noir (black cobalt ochre).
140. C. arseniaté (red cobalt ochre).
9th genus. Arsenic.
141. A. natif (native arsenic).
142. A oxidé (arsenic bloom).
143. A. sulfuré (yellow and red orpiment).
10th genus. Manganèse.
144. M. oxidé (gray and black manganese ore); and, as appendix,
M. oxidé carbonaté (red manganese ore).
145. M. sulfuré (manganese glance, K).
146. M. phosphaté ferrifère (phosphor. mangan, K).
11th genus. Antimony.
147. A. natif. (native antimony).
148. A. sulfuré (gray antimony ore).[1]
149. A. oxidé (white antimony ore; antimony ochre).
150. A. oxidé sulfuré (red antimony ore).
12th genus. Uran.
151. U. oxidulé (pitch ore).
152. U. oxidé (uran mica; uran ochre).
13th genus. Molybdena.
153. M. sulfuré (molybdena).
14th genus. Titahe.
154. T. oxidé (rutil; menakan).
155. T. anatase (octaedrit).
156. T. siliceo-calcaire (sphen).
15th genus. Scheelin.
157. S. ferruginé (wolfram).
158. S. calcaire (tungsten).
16th genus. Tellure.
159. T. natif; auro-ferrifèré (native sylvan), argentifère (graphic ore); auro-plombifère (nagyag ore.)
17th genus. Tantale.
160. T. oxidé ferro-manganésifère (tantalit, K). and ytirifère (yttro-tantalite, K).
18th genus. Cerium.
161. C. oxidé silicifère (cererit, K).

The abbé Haüy's works are the first in which a truly scientific exposition of crystallography is to be found; but, by designating most of the forms by separate names, he has presented them to the mind rather as independent individuals than as parts of such groups as should render their relations to each other, and hence their mineralogical relations, apparent. One of his sources of error may be discovered in an apparently groundless notion that nature has imposed limits to the angles at which the primary planes of crystals incline to each other. And some of the mistakes which originate from this supposition are so important as to cast a shade of doubt over his determinations relative to the primary forms of crystals. His inaccuracy with respect to the angle of carbonate of lime is a well known example of one of these theoretic errors. And, by assigning to the magnesian and ferriferous carbonates of lime the same angle as to the simple carbonate, the error became still greater. His inaccurate measurements of many of the angles of crystals have probably been occasioned by the comparatively imperfect instrument with which they were taken. That he should conti-

nue to prefer this to the more perfect goniometer invented by Dr. Wollaston may possibly have been owing to the decay of sight incident to that period of his life when he first entered into these investigations, and to that dislike to change which is frequent in old age. Although the measurements above quoted have been since repeatedly verified by experiment, the abbé not only continued to insist on the superior accuracy of his own measurements, but discusses, through several pages, how it could have happened that the iron should have displaced the lime in the crystals of carbonate of iron, which his original error led him to regard as pseudomorphous. With all the inaccuracies, however, which his works contain, they present to the reader truly philosophical views of the sciences of which they treat, and cannot be perused without affording considerable gratification and improvement.

The labors of M. C. S. Weiss, formerly professor of mineralogy at Leipzic, and now we believe in the university of Berlin, have greatly contributed to the advancement of mineralogical and crystallographic knowledge. His first paper, which contains some valuable remarks on the different axes of the primitive forms, was published in 1815, and is entitled Des Divisions Naturelles des Systemes de Cristallization. In 1817 a memoir of his appeared in the Transactions of the Academy of Berlin, explaining his method of describing all the crystalline faces of any system whatever, in relation to the fundamental axes of the system, which is, however, too elaborate for us to detail.

We must now proceed to the consideration of the most celebrated of the modern systems of mineralogy, viz. that of professor Mohs, of Freiburg, which has been followed by Jameson of Edinburgh, and, indeed, by most of the mineralogists of the present day. A pupil of the celebrated professor has, in the third volume of the Edinburgh Philosophical Transactions, given the most concise and lucid exposition of the principles upon which his crystallographic and mineralogical systems are founded, that has yet appeared in this language. We could wish that our limits would allow us to give it entire; but, as this is not the case, we shall endeavour to present the reader with an abridgment of his principal remarks.

The following problem is presented as an example of the method in which the simple forms are discovered to be combined in the compound ores. Let fig. 1. Plate I., MINERALOGY, represent a crystallisation of calcareous spar. The form is a compound one, and all the faces of the same description belong to the same simple form contained in it. The junction of those simple forms is symmetrical, because it possesses the highest degree of regularity which their nature and position can permit. The symmetry in this case is expressed by the parallelism of the several edges of combination; and the general problem of crystallography is here transformed into the special one, of finding the circumstances under which the edges of combination obtain their parallelism. If in any combination the homologous faces (the faces agreeing in figure and position) are enlarged, till, all the rest having disappeared, they alone bound the whole solid on every side, the simple forms which the combination included, will successively appear. By this operation, from the faces *g*, P, *f*, *m*, *b*, of fig. 2, we obtain five rhomboids (figs. 3, 4, 5, 6); and from the planes *x*, *y*, *a*, three scalene six-sided pyramids,—pyramids consisting of scalene triangles, as in fig. 10.

The rhomboids have a particular arrangement in the combination, viewed in the distribution presented by this example, the edges of any rhomboid; and the oblique diagonals drawn upon the faces of the one which follows it, lie in the same vertical plane. Such combinations as do not include an uneven number of rhomboids are arranged so that the edges of one rhomboid lie in the same vertical plane with the edges of the next, and the diagonals of the one with the diagonals of the next. In figs. 3, 4, 5, 6, and 10, this arrangement is observable.

If the faces of any two rhomboids, which stand contiguous in the above-mentioned order, *g* and P for instance, or P and *f*, or *f* and *m*, or *m* and *b*, of fig. 2, are simultaneously enlarged, till all the other faces disappear, and the faces of this pair include the whole solid; a form results, which is a combination of those rhomboids, and the edges of combination made by its faces with each other are parallel, as in fig. 1. This parallelism evidently arises from the dimensions of the rhomboids, in other words, from the magnitude of their angles, because it disappears whenever the dimensions of the one or the other are changed. The foregoing problem, therefore, requires to find the ratio of the dimensions by which the edges of combination are rendered parallel.

Solution.—Place a rhomboid in such a position that the straight line passing through two corners (solid angles) formed by equal plane angles, may be vertical. Those corners are named the summits that line the axis. In this position the rhomboid stands upright. Rhomboids, therefore, stand upright when their axes are perpendicular. From those solid angles of a rhomboid, which are not summits, let fall perpendiculars upon a horizontal plane, and connect the points where they meet the plane by straight lines. The figure which results will be a regular hexagon; it is called the horizontal projection of the rhomboid.

Derivation of a more obtuse rhomboid.—Bring a rhomboid into the upright position; and through those edges which meet in the extremity of the axis, stretch planes equally inclined to the faces of the rhomboid. Extend these planes till they all intersect each other: the solid bounded by them will in its turn be a rhomboid. Figs. 4 and 5, fig. 5 the original, fig. 4 the derived with the original. The axis of this new rhomboid is equal to that of the preceding. The horizontal projection is equal in area to four times, in periphery to twice, the horizontal projection of the latter. Together they produce parallel edges of combination. This new rhomboid has a position different from that of the

first. The edges of the former have a similar situation with the oblique diagonals of the latter; that is to say, they lie in the same vertical plane with those diagonals. If sections are drawn parallel to the faces of the new rhomboid, and lying nearer the axis or middle point, those sections will truncate the edges of the original rhomboid: from which will arise the form of a combination of two rhomboids, having the edges of combination parallel.

To give the foregoing proportions a more convenient expression, suppose the horizontal projections of the rhomboids, or the sides of those projections, to be equal, the axis of the new rhomboid will then become equal to half the axis of the original rhomboid. It follows that, if two rhomboids produce parallel edges of combination with each other, the axis of the one must be half that of the other, the horizontal projections being equal. This is merely the proportion between the two rhomboids, expressed by their axes, on the supposition of equal horizontal projections. The absolute dimensions of the rhomboids must be such that both together may be capable of contributing to bound the solid.

On each of the obtuse rhomboids formed by the foregoing process the same process may be again repeated. A new rhomboid in its turn will result, whose axis, if the axis of the horizontal projections are equal, being half the rhomboid immediately preceding, will consequently be fitted to produce parallel edges of combination with it.

Inversion of the process.—The process may be inverted. Draw the diagonals; through every two oblique and one horizontal diagonal extend cutting planes, and deduct the portions which lie without them. The remainder, the part enclosed within the cutting planes, will likewise be a rhomboid. The axes of both these rhomboids are equal. The horizontal projection of the new rhomboid is the fourth part of the horizontal projection belonging to the original rhomboid; the sides of the former are equal to half those of the latter; and consequently, when the horizontal projections are considered equal, the axis of the secondary will be double that of the original rhomboid. This process may be continued indefinitely; and, of all the rhomboids that result from it, any two following in immediate succession will always exhibit such mutual proportions as to produce parallel edges of combination with each other.

All those rhomboids which are produced by the above operations are consequently subject to the general law, that, their horizontal projection being equal, their axes must increase or diminish as the powers of the number 2. These axes, therefore, follow each other in a geometrical progression, and the rhomboids constitute a series which may be developed out of any given member, and expanded indefinitely on both sides.

Designation of the series.—Let the fundamental rhomboid be designated by r; the next more acute one, obtained from the second process, by $r+1$, so that this expression may point out the rhomboid's place, or its distance from r; the next more obtuse one, obtained from the first process, by $r-1$, so that by this means the distance or the position, with regard to r, may in like manner be expressed; and the rest in a similar mode; then, if the axis of r is put $=1$, the first of the three following lines will represent the series of rhomboids, the second their axis, and the third those powers of 2 by which they are expressed.

$$\begin{array}{ccccccccc} -- & r-3\,. & r-2\,. & r-1\,. & r\,. & r+1\,. & r+2\,. & r+3 & -- \\ & \tfrac{1}{8}\,. & \tfrac{1}{4}\,. & \tfrac{1}{2}\,. & 1. & 2\,. & 4\,. & 8\,. & \\ & 2^{-3}. & 2^{-2}. & 2^{-1}. & 2^{-0}. & 2^{1}. & 2^{2}. & 2^{3}. & \end{array}$$

These progressions may be prolonged on both sides as far as we please. The horizontal projections being equal, the axes by this means perpetually augment on the one hand, and perpetually diminish on the other. If they become infinitely small, the rhomboids are converted into regular six-sided prisms, the one of which has an axis infinitely great, the other an axis infinitely small. These prisms are named the limits to the series of rhomboids; their designation is $r \pm \infty$: and hence within its limits the series is—

$$r-\infty \text{-----} r-1\,.\,r.\;r+1 \text{-----} r+\infty$$

Base of the regular six-sided prism.	Rhomboid whose axis $=1$.	Unlimited regular six-sided prism.

Forms of infinite dimensions are not exhibited by nature. The limits appear, therefore, only in combinations. The completed regular six-sided prism, as displayed in nature, is a combination of both limiting forms.

Nature confirms the law of this rhomboidal series within its limits in all minerals that assume such forms. In calcareous spar, of which all the figures in plate I. are varieties, let P, fig. 5, be represented by r; that is to say, by the rhomboid which constitutes the basis of derivation, and whose axis has been put $=1$; then is $g=r-1$, fig. 4; $f=r+1$, fig. 6; $m=r+2$, fig. 3. All these rhomboids have pretty exactly the dimensions which they would have if calculated according to the foregoing proportions, from the rhomboid P, estimated $=104°\ 28'$. If, in place of that number, we employ $105°\ 5'$, the result of numerous measurements instituted for this purpose, the dimensions of the derived rhomboids, calculated upon this supposition agree still more exactly with nature. c, fig. 7, is $=r+\infty$.

In different minerals, particularly in calcareous spar, several rhomboids appear which are not included in the preceding series. They still, however, follow the same general law. The terms of the accompanying series are capable of being found by a deduction similar to that used in the principal series; but the narrowness of our limits will not allow us to exemplify this method.

Isosceles six-sided pyramids.—Suppose fig. 8 to represent a crystalline form proceeding from iron-glance. If the faces P are enlarged till they comprehend the entire solid, the figure will be changed into a rhomboid. If the faces s are enlarged till they likewise completely include the whole solid, we obtain an isosceles six-sided pyramid, fig. 9. The faces of the pyramid, uniting with those of the rhomboid, produce parallel edges of combination. The particular relation

of the pyramid to the rhomboid, upon which this parallelism depends, is, that the horizontal projections being equal, the axis of the pyramid is to that of the rhomboid as $\frac{3}{4}$ to 1.

On rhomboids of infinitely great or infinitely small axes, there depend, in like manner, isosceles six-sided pyramids of infinitely great or infinitely small axes. They also are regular six-sided prisms, distinguished from the preceding by their different position in combinations. These prisms constitute, moreover, the limits of the isosceles six-sided pyramids.

Di-rhomboid.—Bisect those edges of the rhomboid which do not meet the axis. Connect the points of bisection and the summits of the rhomboid by straight lines, and through these lines extend cutting-planes which may take away from the rhomboid segments, such as *f*, *k*, *l*, fig. 12. The remainder will be an isosceles six-sided pyramid, represented in fig. 9. This pyramid must not be confounded with the preceding, because it has not the same proportions to the rhomboid, from which it originates. If we suppose that a rhomboid, as fig. 12, combines with itself in a position different by 60°, the pyramid will, in like manner, originate from this union. The figure, in consequence of its origin, is therefore not a simple form; but, as it manifests in all respects the same relations as the simple rhomboid, it will henceforth be named a di-rhomboid.

Let any rhomboid be placed in an upright position. Produce the axis, to any distance, equally on both sides of the summits. From the corners of the rhomboid draw straight lines to the extremities of the produced axis, through every contiguous pair of those lines, and the intermediate edge of the rhomboid; let planes be extended; the solid which those planes include will be a scalene six-sided pyramid, fig. 10. In this pyramid the edges which do not meet at the summit occupy the same position as the corresponding edges of the rhomboid; they are hence named rhomboidal edges; the others pyramidal or axis edges. Of a scalene six-sided pyramid, whose rhomboidal edges agree in situation with the same edges of a rhomboid, we say that it is derived from the rhomboid, or depends upon it.

Nature presents no scalene-pyramids, but such as are capable of uniting among themselves, or with other forms derived from the rhomboid, to produce symmetrical combinations. We obtain pyramids of this sort, if the axis of the rhomboid from which they are derived (32) is in the first place doubled, in the second tripled, and in the third place quintupled. A pyramid obtained by doubling the axis is called a primary, by tripling it a secondary, and by quintupling it a ternary pyramid. Primary pyramids of this species are designated by $(p \pm n)'$; secondary pyramids by $(p \pm n)''$; ternary by $(p + n)'''$; so that the primary pyramid depending on r would be marked $(p)'$; the secondary $(p)''$; the ternary $(p)'''$; the primary pyramid depending on $r + 2$ would be marked $(p + 2)'$; the secondary $(p + 2)''$; the ternary $(p + 2)'''$.

The regular six-sided prism has already been considered as a rhomboid with an axis infinitely great. The question now arises, what will be the condition of a primary, secondary, or ternary pyramid, originating from a rhomboid with an axis infinitely great? Draw two sections perpendicular to the axis of a pyramid, and so as to pass through the extreme points of the rhomboidal edges. The surfaces of these sections will be irregular hexagons, whose angles have a fixed relation to those of the transverse section. Examine now that segment of the pyramid comprised between the two sections just drawn. Its length, or altitude, is one-third of the axis of that rhomboid from which the pyramid is derived. Hence, if the rhomboid's axis be infinite, the altitude of this segment must likewise be infinite.

Besides those two faces, which are perpendicular to the axis, this segment is bounded by twelve scalene triangles. In proportion as the ratio of the rhomboid's axis to the side of its horizontal projection augments, so much the nearer will two of the angles in each triangle approach to 180°,—the third to 0°; and when the rhomboid's axis, in comparison with the side of its horizontal projection, becomes infinite, and the rhomboid thus changes into a regular six-sided prism, then the bounds are reached, the triangles become unlimited parallelograms, and the middle segment of the pyramid becomes an unlimited irregular twelve-sided prism. This prism will have for its base the transverse section of the primary pyramid, if the middle segment in question belongs to a primary pyramid; the transverse section of the secondary, when that segment belongs to a secondary pyramid; and the transverse section of a ternary, when to a ternary pyramid. The rhomboid, with its axis infinitely great, that is to say, the regular six-sided prism constituting the limit of the rhomboidal series, has thus dependent on it three scalene six-sided pyramids, also with axes infinitely great, of which one is a primary, the next a secondary, the last a ternary; and which, therefore, assume the appearance of irregular twelve-sided prisms, each dependent on its appropriate transverse section. These prisms are the limits of the scalene six-sided pyramids. It is observable that the regular six-sided prisms, which form the limits of the isosceles pyramids, have no twelve-sided prisms of this sort: hence these prisms appear in combinations, only in one and the same position. These prisms which, like all forms having one of their dimensions unlimited, can only appear in combinations, are exemplified by nature, in tourmaline, in emerald; some of their faces are found even in calcareous spar. In tourmaline, the prism, which depends on the secondary pyramid, is designated by *h*; the general expression for these prisms is $(p \pm \infty)^m$, where m, as above, signifies the characters $'$, $''$, $'''$.

On glancing back over the ground we have passed, one is astonished at the multitude and variety of forms which may be deduced from a given rhomboid, and submitted to very simple laws; yet the whole compass of this subject is still far from exhausted, and many remarkable phenomena relating to it have been omitted for want of room. Nature combines these forms in crystalline figures. From their dependence upon each other, and from the proportions in which

...ly stand, we may comprehend that ...nations must possess the highest ...ity admitted by their simple ... be completely symmetrical. ...f the enquiry nothing is ...ing a palpable represen... ...han to study the crys... ...ar; and nothing for ...but that study than ...e proportions are on ...d that symmetry.

...s, with square bases.—Be... ...eady noticed, no other can ... the rhomboid. Hence, no ...le of entering into combination ...omboid, or with any form derived ...f, however, we take a four-sided pyramid having a square base, fig. 13, and treat it ...escribed, we shall obtain a series of four-...ded pyramids with square bases, which will proceed according to the powers of $\sqrt{2}$, and whose limits will be rectangular four-sided prisms. As the horizontal projections of two consecutive pyramids are not parallel to each other, these prisms must be regarded as in two different positions.

Nature demonstrates the existence of this series within its limits, in the case of zircon, tungsten, vesuvian, tinstone, yellow-lead, uran-mica, rutule, anatase, and others. Upon this series depends also an accompanying series of four-sided pyramids, with square bases; its coefficient is $\frac{3}{2\sqrt{2}}$.

Scalene eight-sided pyramid.—Three pyramids of this kind depend upon each four-sided one with a square base, in the principal series; and the axes of the former are to those of the latter as 3 : 1, 4 : 1, 5 : 1. In the order here assigned to them, like the six-sided pyramids formerly mentioned, they are named the primary, secondary, and ternary. The manner in which these eight-sided pyramids originate from the four-sided pyramids cannot, however, be here detailed for want of room. The limits which bound this single series of eight-sided pyramids are eight-sided prisms, having the same unequal angles as the transverse section of the pyramid to which they belong. Since the horizontal projections of two consecutive four-sided square-based pyramids occupy different places, these prisms must be considered as having two different positions.

Nature displays the existence and the limits of this series of eight-sided pyramids in the following examples. In zircon, fig. 13 and 14, let P be $= p$; then is $x = (p)'$, that is to say, the simple form that arises from augmenting the faces, *f*, is the primary scalene eight-sided pyramid, originating from the four-sided square-based one, designated by P; and the axis of the former is consequently equal to three times that of the latter. In this same mineral are likewise found $(p)''$ and $(p)'''$; as the Institute's collection exemplifies. Whatever was above established, respecting those forms which originate in rhomboids, may also be applied to those forms which originated in four-sided square-based pyramids, The remarkable analogy which exists in all points between the one class and the other, contributes not a little to augment the interest arising from the study of both. The latter, like the former, constitute among themselves a group, and produce symmetrical combinations, into which they admit nothing that cannot be derived from the fundamental form, in the mode already explained.

Four-sided pyramids with oblique bases.—A similar group will result, if, with some very slight alterations, we apply the process of derivation, explained above, to a four-sided pyramid with an oblique base. From that operation several series of four-sided oblique-based pyramids arise; in some of which the transverse section at right angles to the axis is similar to the transverse section of the original pyramid; in others not. The limits of these series are oblique-angled four-sided prisms, whose axis, if the pyramid is in its upright position, are vertical. By this derivation, however, we also obtain prisms whose axes (the fundamental oblique-based four-sided prism being in its upright position) lie horizontally, and are parallel to the diagonals of the oblique base. From the union of two horizontal prisms, a form results which some crystallographers have named a four-sided pyramid, with a longish rectangular base.

Hexahedron, and the forms that result from it.—A multitude of forms yet remain which are not connected with any of the preceding. Such are those that possess the greatest, sometimes even a geometrical regularity in their simple forms, and the highest degree of symmetry in their combinations. They can all be derived from the hexahedron (cube), by placing it upright, and considering the position of a moveable plane with regard to its faces and edges. Forms of this sort, never assuming infinite directions, have no limit like the preceding. Some of them, however, have constant dimensions, while the dimensions of others are variable. The former may be viewed as limits of the latter. Every simple form, from which other simple forms are derived, is called a fundamental form; and the class of figures derived from that fundamental form, a system of crystallisations. Hence, in the mineral kingdom, there are four fundamental forms, and four systems of crystallisations. The rhombohedral; the pyramidal, derived from a four-sided isosceles pyramid; the prismatic, derived from a scalene four-sided pyramid; and, lastly, the tessular, or that which is derived from the hexahedron.

Three of our fundamental forms are indeterminate in their dimensions; the fourth, the hexahedron, is constant in its dimensions. The dimensions of all derived forms depend upon those of the fundamental forms, the variations of which they follow to their limits, in the rhomboidal and pyramidal systems: and in the prismatic system, to the rectangular four-sided prism, which remains always the same, how different soever the dimensions of the fundamental forms may become. In any of these three systems, if the dimensions of the fundamental form are determined, we obtain from it, by derivation, a train of forms having determinate dimensions, among which the general proportions of the

system are observed. Whenever the dimensions of the fundamental form are altered, the dimensions of all such forms as result from it are altered likewise, without, however, changing the mutual ratios which they bear to each other.

The different series of crystallisations are of the highest importance for properly determining the species of minerals, the systems of crystallisations for determining their characteristics. And, as all minerals do not present themselves in a crystallised state, the cleavage comes forward to compensate for the absence of crystallisation; because any form of cleavage, not a limiting form, represents some member in the series of crystallisations belonging to that species. A limiting form, however, determines the system of crystallisations, provided it be not a straight four-sided rectangular prism, in which case the choice, lying between the pyramidal, prismatic, and tessular systems, must be determined by the circumstances.

When any cleavage form is a straight rectangular four-sided prism, though from any other quarter the smallest hint were not given us by which the particular system of crystallisations it belongs to could be determined, the following simple considerations will be sufficient to fix that point:—A straight four-sided prism presented to us may be 1. The hexahedron. 2. The limits of the pyramidal system. 3. A combination of the limiting forms of the prismatic system. If the faces of the cleavage, in regard to their completeness and lustre, are each of a different nature, the form comes under the first case. If two faces of the cleavage are of the same, the third of a different nature, then the form must come under the third case. Examine the cleavage in the direction of the diagonal. If this, once more, affords a rectangular four-sided prism, it indicates the pyramidal system; if it affords an oblique angular four-sided prism, it indicates the prismatic system. When all the cleavage faces are of the same nature, the form may come under any of the whole three cases. Between the second and the third a decision must be made as above. If the additional cleavage produces a rectangular four-sided prism, seek to obtain the same figure in the direction of another axis. If we obtain it, the form is a hexahedron; if we cannot obtain it, the form is the limit of the pyramidal system.

It is well known how far our judgments of cleavage and cleavage-forms are rendered easy and certain by a little practice. To such a degree is this the case, that an observer can often, with great facility, determine the form in minerals, which, but for this simple artifice, would scarcely have exhibited to us any traces of regular conformation. All these and similar advantages assist us in applying the system of crystallisations to the purpose of determining minerals. But, notwithstanding the universality of its application, nothing can be accomplished by means of it alone. To render it effectual, some other characteristics must be combined with it. Specific gravity, hardness, and lustre are the most important of these characters.

The remarks on mineralogical nomenclature in this sketch are, however, too important to be omitted.

The word with which we designate a single object, remarks our author, is called a name. This object may be such as to include a number of others. If the name has an epithet annexed, it is called a denomination. This denomination no longer designates that object on which the name was bestowed, but some single object included under it; and this last may, in its turn, include other objects. This distinction between names and denominations will afterwards be useful on account of brevity.

By names alone no mutual relation of the things which bear them can ever be expressed. A denomination effects this; the name, by its annexed epithet, marking a stricter designation. Hence, in a systematic nomenclature, the species bear denominations not names.

To give the name a more definite signification in the case of the species, it is applied to the genus, or the order, or some of the higher steps of classification. The name refers not to one single production of nature, or to one species, but to a class of greater extent; it reaches to the former only in so far as their characters entitle them to a place under that class. It is by this arrangement that the systematic nomenclature is enabled to restrict the arbitrary application of names. A newly discovered mineral, though not belonging to any known species, would probably belong to some known genus, and therefore obtain the name of that genus, or to some known order, and hence take its name from that order.

The names M. Mohs has employed are, pyrites, ore, glance, spar, &c. The term pyrites has already been applied to certain minerals belonging to one order; it is, therefore, employed to denote an order. Some other substances, which likewise belong to that order, have therefore necessarily received this designation, and laid aside their previous names,—nickel, for example, glance-cobalt, and others. The signification of the order settles what is or is not pyrites; and whatever, according to that signification, is pyrites,—in other words, whatever belongs to the order bearing this name, must also be called pyrites. The same kind of management has been followed with the other names, as may be seen by inspecting the mineralogical system, to which the new nomenclature is applied.

Next to the name, the most important point is the first restriction of it, that adjunct, to-wit, by which the name of an order is transformed into the name of a genus. The generic name ought to be founded on the natural historical nature of the genus. Of this kind are garnet-blend, ruby-blend, glance-blend. These three genera all belong to the order of blends. The first, however, has the appearance of garnet; the second, at least in some varieties, of ruby; the third of glance. This mode of forming the generic name would, doubtless, be the most advantageous, because it leads to no delineations which are foreign to natural history. It cannot, however, be universally applied, without introducing a multitude of new names; and hence, in conformity to the previous rule, with the sacrifice of uniformity it is true, two other means have been attempted. The first is to make use of some customary trivial names for settling the genera; the other to apply to this an arrangement not

properly arising from natural history. On the former principle are felspar, augite-spar, azure-spar, on the latter, iron-pyrites, cobalt-pyrites, lead-glance, molybdenum-glance, and others. No doubt, the second class of names have a chemical sound; but they have no chemical meaning; and all depends upon the meaning. Of a similar, yet not altogether identical nature, are fluor-haloid, calcareous-haloid, gypsum-haloid; but not less exceptionable in that respect.

The farther restriction of the generic names into specific ones is brought about simply by means of an adjective, indicating the systems of crystallisations, or some relation of the cleavage, or in general that character by which the species of a genus are most advantageously distinguished. Such are hexahedral, prismatic, rhomboidal, iron-pyrites; rhomboidal, octahedral, prismatic corundum; octahedral, rhomboidal, prismatic iron ore, and many others. When the forms of two species in a genus belong to the same system of crystallisations, the same process is followed; to the one adjective is joined another, by which the nature of the cleavage is more accurately denoted. This has been done in cases such as rhomboidal and prismato-pyramidal titanium ore and the like. In these instances no idea must be entertained of the transposition or mingling of two systems of crystallisations. In the first example the denomination merely signifies, that the form of the species belongs to the rhomboidal system, and that the cleavages, on the other hand, takes place according to prisms which can be no other than regular six-sided prisms. In the second example the denomination indicates, that the forms belong to the pyramidal system, and that the cleavage takes place according to prisms which must, therefore, be rectangular four-sided prisms. When the system of crystallisation and the cleavages of two or more species agree, as in several calcareous haloids, augite-spars, and others, a particular property of the crystallisations, &c., is chosen to form the special denomination; such as long or short-axed, right or oblique angled, and so on. The term axifrangible, or axis-cleaving, denotes a particular direction of cleavage perpendicular to the axis, as in axifrangible zeolite; prismatoidal denotes one particular direction of cleavage, parallel to the axis, as in prismatoidal antimony-glance.

Professor Mohs has arranged the mineral kingdom under three classes.

Class I.

If solid; sapid. No bituminous odor. Sp. gr. under 3·8. It has four orders.

Order I.—Gas.

Expansible. Not acid.

Order II.—Water.

Liquid. Without odor or sapidity. Sp. gr. 1

Order III.—Acid.

Acid. Sp. gr. 0·0015 to 3·7.

Order IV.—Salt.

Not acid. Sp. gr. 1·2 to 2·9.

Class II.

Insipid. Sp. gr. above 1·8.

Order I.—Haloide (salt-like).

Not metallic. Streak uncolored.

If pyramidal or prismatic; H. hardness, = 4 and less. If tessular, H. = 4·0. If single, perfect, and eminent faces of cleavage; sp. gr. = 2·4 and less.

H. = 1·5 to 5·0. If under 2·5, sp. gr. = 2·4 and less. Sp. gr. = 2·2 to 3·3. If 2·4 and less, H. under 2·5; and no resinous lustre.

Order II.—Baryte.

Not metallic. If adamantine or imperfect metallic lustre; sp. gr. = 6·0 and more. Streak uncolored, or orange-yellow. If orange-yellow; sp. gr. = 6·0 and more, and H. = 3·0 and less.

H. = 2·5 to 5·0. If 5·0; sp. gr. under 4·5.

Sp. gr. = 3·3 to 7·2. If under 4·0 and H. = 5·0; cleavage diprismatic.

Order III.—Kerate (Horny).

Not metallic. Streak uncolored. No single eminent cleavage. H. = 1·0 to 2·0. Sp. gr. = 5·5.

Order IV.—Malachite.

Not metallic. Color blue, green brown. If brown color of streak; H. = 3·0 and less; and sp. gr. above 2·5. If uncolored streak; sp. gr. = 2·2 and less; and H. = 3·0. No single eminent faces of cleavage. H. = 2·0 to 5·0. Sp. gr. = 2·0 to 4·6.

Order V.—Mica.

If metallic; sp. gr. under 2·2. If not metallic; sp. gr. above 2·2. If yellow streak, pyramidal. Single eminent cleavage. H. = 1·0 to 4·5. If above 2·5; rhombohedral. Sp. gr. = 1·8 to 5·6. If under 2·5; metallic. If above 4·4; streak uncolored.

Order VI.—Spar.

Not metallic. Streak uncolored, brown. If rhombohedral; sp. gr. 2·2 and less, or H. = 6·0.

H. = 3·5 to 7. If 4·0 and less; single eminent cleavage. If above 6·0; sp. gr. under 2·5, or above 2·8; and pearly lustre. Sp. gr. = 2·0 to 3·7. If above 3·3; hemiprismatic, or H. = 6·0; and no adamantine lustre. If 2·4 and less; not without traces of form and cleavage.

Order VII.—Gem.

Not metallic. Streak uncolored. H. = 5·5 to 10. If 6·0 and less; sp. gr. = 2·4 and less; and no traces of form and cleavage. Sp. gr. = 1·9 to 4·7. If under 3·8; no pearly lustre.

Order VIII.—Ore.

If metallic; black. If not metallic; adamantine, or imperfect metallic lustre. If yellow or red streak; H. = 3·5 and more; and sp. gr. = 4·8 and more. If brown or black streak; H. = 5·0 and more, or perfectly prismatoidal. H. = 2·5 to 7·0. If 4·5 and less; red, yellow, or black streak. If 6·5 and more; and streak uncolored; sp. gr. = 6·5 and more. Sp. gr. = 3·4 to 7·4.

Order IX.—Metal.

Metallic. Not black. If gray; malleable; and sp. gr. = 7·4 and more. H. = 0·0 to 4·0, or malleable. Sp. gr. = 5·7 to 20·0.

Order X.—Pyrites.

Metallic. H. = 3·5 to 6·5. If 4·5 and less; sp. gr. under 5·0. Sp. gr. = 4·1 to 7·7. If 5·3 and less; color yellow or red.

Order XI.—Glance.

Metallic. Gray, black. H. = 1·0 to 4·0. Sp. gr. = 4·0 to 7·6. If under 5·0, and single perfect cleavage: lead-gray. If above 7·4; lead-gray.

Order XII.—Blende.

If metallic; black. If not metallic; adamantine lustre. If brown streak; uncolored. Sp. gr. between 4·0 and 4·2; and the form tessular. If red streak; sp. gr. = 4·5 and more; and H. = 2·5 and less.

H. = 1·0, 4·0. Sp. gr. = 3·9, 8·2. If 4·3 and more; streak red.

Order XIII.—Sulphur.

Not metallic. Color red, yellow, or brown. Prismatic. H. = 1·0 to 2·5. Sp. gr. = 1·9 to 3·6. If above 2·1; streak yellow, or red.

Class III.

If fluid; bituminous odor. If solid; insipid. Sp. gr. under 1·8.

Order I.—Resin.

Fluid, solid. Streak uncolored, yellow, brown, black. H. = 0·0 to 2·5. Sp. gr. = 0·7 to 1·6. If 1·2 and more; streak uncolored.

Order II.—Coal.

Solid. Streak, brown, black. H. = 0·1 to 2·5. Sp. gr. = 1·2 to 1·5.

The following is his arrangement of simple minerals:—

Class I.

Order I.—Gas.

Genus I. Hydrogen gas.
1. Pure hydrogen gas.
2. Carbureted hydrogen gas.
3. Sulphureted hydrogen gas.
4. Phosphureted hydrogen gas.

Genus II. Atmospheric air.
1. Pure atmospheric air.

Order II.—Water.

Genus I. Atmospheric water.
1. Pure atmospheric water.

Genus II. Sea water.
1. Common sea water.

Order III.—Acid.

Genus I. Carbonic acid.
1. Aëriform carbonic acid.

Genus II. Muriatic acid.
1. Aëriform muriatic acid.

Genus III. Sulphuric acid.
1. Aëriform sulphuric acid.
2. Liquid sulphuric acid.

Genus IV. Boracic acid.
1. Prismatic boracic acid.

Genus V. Arsenic acid.
1. Octahedral arsenic acid.

Order IV.—Salt.

Genus I. Natron.
1. Prismatic natron.

Genus II. Glauber's salt.
1. Prismatic Glauber's salt.

Genus III. Nitre.
1. Prismatic nitre.

Genus IV. Rock salt.
1. Hexahedral rock salt.

Genus V. Sal ammoniac.
1. Octahedral sal ammoniac.

Genus VI. Vitriol.
1. Hemiprismatic vitriol, or green vitriol.
2. Prismatic vitriol, or blue vitriol.
3. Pyramidal vitriol, or white vitriol.

Genus VII. Epsom salt.
1. Prismatic Epsom salt.

Genus VIII. Alum.
1. Octahedral alum.

Genus IX. Borax.
1. Prismatic borax.

Genus X. Glauberite.
1. Prismatic glauberite.

Class II.

Order I.—Haloide.

Genus I. Gypsum.
1. Prismatoidal gypsum, or common gypsum.
2. Prismatic gypsum, or anhydrite.

Genus II. Cryolite.
1. Prismatic cryolite.

Genus III. Alum stone.
1. Rhomboidal alum-stone.

Genus IV. Fluor.
1. Octahedral fluor.

Genus V. Apatite.
1. Rhomboidal apatite.

Genus VI. Limestone.
1. Prismatic limestone, or arragonite.
2. Rhomboidal limestone.
3. Macrotypous limestone.
4. Brachytypous limestone, or rhomb-spar.

Order II.—Baryte.

Genus I. Sparry iron.
1. Rhomboidal sparry iron.
* Spharosiderite.

Genus II. Red manganese.
1. Rhomboidal red manganese
* Manganese spar.

Genus III. Calamine
1. Prismatic, or electric calamine.
2. Rhomboidal calamine.

Genus IV. Tungsten, or scheelium.
1. Pyramidal tungsten.

Genus V. Baryte.
1. Pyramido-prismatic baryte, or strontianite.
2. Di-prismatic baryte, or witherite.
3. Prismatic baryte, or heavy spar.
4. Prismatoidal baryte, or celestine.

Genus VI. Lead-spar.
1. Di-prismatic lead-spar, or white and black lead-spar.
2. Rhomboidal lead-spar, or green and brown lead-spar.
3. Hemiprismatic lead-spar, or red lead-spar.
4. Pyramidal lead-spar, or yellow lead-spar.
5. Prismatic lead-spar, or sulphate of lead.
* 1. Corneous lead-spar.—2. Arseniate of lead.—3. Plomb Gomme.

Order III.—Kerate.

Genus I. Corneous silver.
1. Hexahedral corneous silver.

Genus II. Corneous mercury.
1. Pyramidal corneous mercury.

Order IV.—MALACHITE.

Genus I. Copper green.

1. Uncleavable copper green.

Genus II. Liriconite.

1. Prismatic liriconite, or lenticular arseniate of copper.
2. Hexahedral liriconite, or cubical arseniate of iron.

Genus III. Olivenite.

1. Prismatic olivenite, or prismatic arseniate of copper.
2. Di-prismatic olivenite.

Genus IV. Blue malachite, or blue copper.

1. Prismatic blue malachite.
   * Velvet blue copper.

Genus V. Emerald malachite.

1. Rhomboidal emerald malachite.

Genus VI. Green malachite.

1. Prismatic green malachite, or phosphate of copper.
2. Di-prismatic green malachite, or common malachite.
   * Atacamite.
1. Prismatic atacamite, or muriate of copper.

Order V.—MICA.

Genus I. Copper mica.

1. Rhomboidal copper mica, or micaceous arseniate of copper.
2. Prismatic copper-mica.

Genus II. Uran-mica, or uranite.

1. Pyramidal uran-mica.
   * Uran-ochre.

Genus III. Cobalt-mica, or red cobalt

1. Prismatic red cobalt.

* Cobalt-ochre.
1. Black cobalt-ochre.
2. Brown cobalt-ochre.
3. Yellow cobalt-ochre.

Genus IV. Antimony-mica, or white antimony.

1. Prismatic white antimony.
   * Antimony ochre.

Genus V. Blue iron, or iron mica.

1. Prismatic blue iron, or phosphate of iron.

Genus VI. Graphite.

1. Rhomboidal graphite.

Genus VII. Talc-mica.

1. Prismatic talc-mica, or talc.
   * 1. Native magnesia, or hydrate of magnesia.—2. Ophite.—3. Pikrolite.—4. Nephrite.—5. Steatite, or soap stone.—6. Figurestone, or algalmatolite.—7. Magnesite.—8. Meerschaum.—9. Lithomarge.—10. Mountain soap.—11. Bole.
2. Rhomboidal talc mica, or common mica.
   * Pinite.

Genus VIII. Pearl-mica.

1. Rhomboidal pearl-mica.

Order VI.—SPAR.

Genus I. Schiller-spar.

1. Diatomous schiller-spar, or common schiller-spar.
2. Axotomous schiller-spar, or green diallage.
3. Hemiprismatic schiller-spar, or bronzite.
4. Prismatoidal schiller-spar, or hypersthene.
5. Prismatic schiller-spar, or anthophyllite.

Genus II. Kyanite.

1. Prismatic kyanite.

Genus III. Spodumene.

1. Prismatic spodumene.

Genus IV. Prehnite.

1. Axotomous prehnite.
   * Karpholite.

Genus V. Datolite.

1. Prismatic datolite.

Genus VI. Zeolite.

1. Trapezoidal zeolite, or leucite.
2. Dodecahedral zeolite, or sodalite.
3. Hexahedral zeolite, or analcime.
4. Paratomous zeolite, or cross-stone.
5. Rhomboidal zeolite, or chabasite.
6. Diatomous zeolite, or laumonite.
7. Prismatic zeolite, or mesotype.
8. Prismatoidal zeolite, or stilbite.
9. Hemiprismatic zeolite.
10. Pyramidal zeolite, or albine.
11. Axotomous zeolite, or apophyllite.

Genus VI. Petalite.

1. Prismatic petalite.

Genus VII. Felspar.

1. Rhomboidal felspar, or nepheline.
2. Prismatic felspar, or common felspar.
3. Pyramidal felspar, or scapolite, &c.
   * Elaolite.

Genus VIII. Augite.

1. Paratomous augite, or common augite, &c.
2. Hemiprismatic augite, or hornblende, &c.
3. Prismatic augite, or epidote.
4. Prismatic augite, or tabular spar.

Genus IX. Azure-spar.

1. Prismatic azure-spar, a lazulite.
2. Prismatoidal azure-spar, or blue spar.
   * 1. Azure-stone, or lapis lazuli.—2. Hauyne.—3. Calaite, or mineral turquois.—4. Amblygonite.—5. Diaspore.—6. Gehlenite.

Order VII.—GEM.

Genus I. Andalusite.

1. Prismatic andalusite.
   * Fibrolite. ** Chiastolite.

Genus II. Corundum.

1. Dodecahedral corundum, or spinel.
2. Octahedral corundum, or automolite.
3. Rhomboidal corundum, or sapphire.
4. Prismatic corundum, or chrysoberyl.

Genus III. Diamond.

1. Octahedral diamond.

Genus IV. Topaz.

1. Prismatic topaz.

Genus V. Emerald.

1. Prismatic emerald, or euclase.
2. Rhomboidal emerald.

Genus VI. Quartz.

1. Prismatic quartz, or iolite.
2. Rhomboidal quartz.
3. Uncleavable quartz.
4. Fusible quartz.

Genus VII. Axinite.

1. Prismatic axinite.

Genus VIII. Chrysolite.

1. Prismatic chrysolite.

Genus IX. Boracite.

1. Octahedral boracite

Genus X. Tourmaline.
1. Rhomboidal tourmaline.
Genus XI. Garnet.
1. Pyramidal garnet, or vesuvian.
2. Tetrahedral garnet, or helvine.
3. Dodecahedral garnet.
4. Prismatic garnet, or cinnamon-stone.
5. Prismatoidal garnet, or grenatite.
* Aplome. Eudialite.
Genus XII. Zircon.
1. Pyramidal zircon.
Genus XIII. Gadolinite.
1. Prismatic gadolinite.

Order VIII.—Ore.

Genus I. Titanium ore.
1. Prismatic titanium ore, or sphene.
2. Peritomous titanium ore, or rutule.
3. Pyramidal titanium ore, or octahedrite.
Genus II. Zinc ore.
1. Prismatic zinc ore, or red zinc ore.
Genus III. Red copper ore.
1. Octahedral red copper ore.
Genus IV. Tin ore.
1. Pyramidal tin ore.
Genus V. Wolfram ore.
1. Prismatic wolfram.
Genus VI. Tantalum ore.
1. Prismatic tantalum ore.
* Tantalite.
Genus VII. Uranium ore.
1. Uncleaveable uranium ore.
Genus VIII. Cerium ore.
1. Uncleavable cerium ore.
* Allanite, or prismatic cerium ore.
** Cerin.
Genus IX. Chrome ore.
1. Prismatic chrome ore, or chromate of iron.
Genus X. Iron ore.
1. Octahedral iron ore, or magnetic iron ore.
* Titanitic iron ore. ** Iserine.
*** Menachanite.
2. Rhomboidal iron ore, or red iron ore.
3. Prismatic iron ore, or brown iron ore.
* Bog iron ore. ** Lievrite.
Genus XI. Manganese ore.
1. Prismatic manganese ore, or black manganese.
* Scaly brown manganese ore.
2. Prismatoidal manganese ore, or gray manganese.
* 1. Earthy gray and brown manganese ore, or wad.—2. Phosphate of manganese.

Order IX.—Native Metals.

Genus I. Arsenic.
1. Native arsenic.
Genus II. Tellurium.
1. Native tellurium.
Genus III. Antimony.
1. Dodecahedral antimony.
2. Prismatic antimony, or antimonial silver.
Genus IV. Bismuth.
1. Octahedral bismuth.
Genus V. Mercury.
1. Liquid native mercury.
2. Dodecahedral mercury, or native amalgam.
Genus VI. Silver.
1. Hexahedral silver.
Genus VII. Gold.
1. Hexahedral gold.
Genus VIII. Platina.
1. Native platina.
Genus IX. Iron.
1. Octahedral iron.
1. Subsp. terrestrial native iron.
2. ——— meteoric native iron.
Genus X. Copper.
1. Octahedral copper.
* 1. Osmium.—2. Palladium.—3. Nickel.

Order X.—Pyrites.

Genus I. Nickel pyrites, or copper nickel.
1. Prismatic nickel pyrites.
* Nickel ochre.
** Black nickel.
Genus II. Arsenic pyrites.
1. Axotomous arsenic pyrites.
2. Prismatic arsenic pyrites.
Genus III. Cobalt pyrites.
1. Hexahedral cobalt pyrites, or silver white cobalt.
2. Octahedral cobalt pyrites, or tin white cobalt.
* Gray cobalt pyrites.
** Cobalt kies.
*** Radiated tin white cobalt pyrites.
Genus IV. Iron pyrites.
1. Hexahedral iron pyrites.
2. Prismatic iron pyrites.
3. Rhomboidal iron pyrites, or magnetic pyrites.
Genus V. Copper pyrites.
1. Pyramidal copper pyrites, or yellow copper pyrites.
Undetermined pyrites.
* 1. Nickeliferous gray antimony.—2. Common tin pyrites.

Order XI.—Glance.

Genus I. Copper glance.
1. Tetrahedral copper glance, or gray and black copper.
2. Prismatoidal copper glance.
3. Prismatic copper glance, or vitreous copper.
* 1. Variegated copper.—2. Argentiferous copper glance.—3. Plumbiferous copper glance.—4. Tennantite.—5. Eukairite.
Genus II. Silver glance, or vitreous silver.
1. Hexahedral silver glance.
Genus III. Galena, or lead glance.
1. Hexahedral galena, or lead glance.
* Blue lead.
Genus IV. Tellurium glance, or black tellurium
1. Prismatic tellurium glance.
Genus V. Molybdena, or molybdena glance.
1. Rhomboidal molybdena.
* Molybdena ochre.
Genus VI. Bismuth glance.
1. Prismatic bismuth glance.
* Bismuth ochre.
** Acicular bismuth glance, or needle ore.
Genus VII. Antimony glance.
1. Prismatic antimony glance.
2. Prismatoidal antimony glance, or gray antimony.
3. Axotomous antimony glance, or bournonite.

Genus VIII. Melane glance.
1. Diprismatic Melane glance, black antimony ore of Werner.
2. Prismatic melane glance, brittle silver glance of Werner.

Order XII.—Blende.

Genus I. Manganese blende.
1. Prismatic manganese blende.

Genus II. Zinc blende, or garnet blende.
1. Dodecahedral zinc blende.

Genus III. Antimony blende, or red antimony.
1. Prismatic antimony blende, or red antimony.

Genus IV. Ruby blende.
1. Rhomboidal ruby blende, or red silver.
2. Peritomous ruby blende, or cinnabar.

Order XIII.—Sulphur.

Genus I. Sulphur.
1. Prismatoidal sulphur, or yellow orpiment.
2. Hemi-prismatic sulphur, or red orpiment.
3. Prismatic sulphur, or common sulphur.

CLASS II.

Order I.—Resin.

Genus I. Mellilite, or honey-stone.
1. Pyramidal mellilite, or honey-stone.

Genus II. Mineral resin.
1. Yellow mineral resin, or amber.
2. Fossil copal.
3. Black mineral resin.
4. Retinite.
5. Dysodilite.

Order II.—Coal.

Genus I. Mineral coal.
1. Bituminous mineral coal.
2. Glance coal.

The nomenclature of the species in the above system is founded on the primitive forms of the minerals, on the nature of their cleavage, or the position of their bevelment. Thus in the genus corundum there are three species, the different primitive forms of which are the octahedron, rhomboid, and prism, and hence these are named octahedral, corundum rhomboidal, corundum and prismatic corundum. In the genus Zeolite there are seven species; one of them is named prismatoidal the cleavage being prismatoidal, another axifrangible on account of its axifrangible cleavage.

Professor Jameson of Edinburgh thoughout his valuable works on mineralogy has adhered to the above system with but few alterations. His definitions of the species, &c., are the same, and also his nomenclature; but he has occasionally altered the order of the genera, and arranged them under four classes instead of three. His system, however, so nearly resembles that of Mohs that it would be difficult to notice them separately.

The celebrated Berzelius has attempted to establish 'A pure scientific system of mineralogy by the application of the electro-chemical theory, and the chemical proportions.' The views which he has disclosed are novel and highly important. He defines mineralogy to be the science which treats of the elementary combinations of unorganic substances found in or upon the earth, and of the various forms and the different foreign admixtures under which these bodies make their appearance. By the influence of electricity on the theory of chemistry, this last science has experienced a greater change than by the doctrines either of Lavoisier or Stahl. The object of Berzelius is to show that the influence of the electro-chemical theory extends as much to mineralogy as to chemistry; and also that the doctrine of definite chemical proportions is equally applicable, and will give the same degree of mathematical certainty to the arrangements of a mineralogical system which it has already given to chemistry. From the electro-chemical theory, we have, says he, been taught to seek in every compound body for ingredients of opposite electro-chemical properties; and we have learned from it that the combinations cohere with a force which is in proportion to the degree of opposition in the electro-chemical nature of the ingredients. Hence it follows that, in every compound body, there are one or more electro-positive, with one or more electro-negative ingredients. By electro-positive ingredients, he designates such as have inflammable bodies, or salts for bases; and, by electro-negative, the oxygen and oxides which go to the negative pole of the Voltaic battery. In other words, every substance called a basis, in chemical combination, must have another which acts the part of an acid, though the latter, when uncombined, may not be distinguished by a sour taste, or the property of changing vegetable blues to red. The body which, in one case, is electro-negative, may, in another case, be electro-positive, and may be united to a stronger electro-negative, that is, it may be the basis to a stronger acid.

That silex performs the functions of an acid in the mineral kingdom was an opinion advanced by Mr. Hume so early as 1805, and he adduces its neutralising effects on alkalies in the formation of glass as an example. Berzelius regards this new view respecting the combinations of silex with different bases as the most important step which mineralogy has yet made towards its perfection as a science. It is the most abundant substance of which the surface of the globe is composed, and, according to Berzelius, the illustration of that order of minerals in which it supplies the place of an acid, being the electro-negative ingredient, throws the greatest light over other branches of mineralogy. The minerals of this order are, however, the most numerous, and he has given to them the name of siliciates. As an acid, silex possesses the property of forming siliciates of many different degrees of saturation. The most common are those in which the silex contains the same quantity of oxygen as does the base. These he denominates simply siliciates. When the silex contains twice the oxygen of the base, they are called bisiliciates. When thrice, trisiliciates. But, when the base contains more oxygen than the silex does, they are called subsiliciates, and are designated by the terms bi-subsiliciates, tri-subsiliciates, &c., to announce that the base possesses twice or three times the oxygen of the silex.

The mineralogical arrangement proposed by

Berzelius, is founded on the order of the electro-chemical properties of bodies, beginning with the most electro-negative oxygen, and terminating with the most electro-positive potassium, and placing every compound body according to its most electro-positive ingredients. But he observes that, in the present state of science, we must be content with an arrangement only approximating to precision. He divides simple bodies into three classes. 1. Oxygen; 2. Simple non-metallic inflammable bodies, which he calls Metalloids; 3. Metals. He arranges them in the order in which they follow one another, from the most electro-negative to the most electro-positive, in every class. This order is nearly as follows:—

1. Oxygen.

2. Metalloids.

Sulphur,	Fluoric radicle,
Nitricum, or the radicle of azote,	Boron,
Muriatic radicle,	Carbon,
Phosphorus,	Hydrogen.

3. Metals.

Arsenic,	Lead,
Chromium,	Tin,
Molybdenum,	Nickel,
Tungsten,	Copper,
Antimony,	Uranium,
Tellurium,	Zinc,
Silicium,	Iron,
Tantalum,	Manganese,
Titanium,	Cirium,
Zirconium,	Yttrium,
Osmium,	Glucinum,
Bismuth? (uncertain)	Alumnium,
Iridium,	Magnesium,
Platinum,	Calcium,
Gold,	Strontium,
Rhodium,	Barytium,
Palladium,	Sodium,
Mercury,	Potassium.
Silver,	

Every one of these bodies can constitute a mineralogical family, which will consist of that single body, and all its combinations with bodies that are electro-negative towards it, that is, all those which with some few exceptions precede it in the above series. Thus there may be as many families as there are simple substances. The families he divides into orders, according to the different electro-negative bodies with which the most electro-negative are combined. It must be confessed that the obstacles which oppose themselves to the formation of a complete mineralogical system, on the principles proposed by Berzelius, appear to be great, particularly with respect to many of the minerals that never occur crystallised, as it seems that we have no means of determining the proper constituent ingredients from the mechanical admixtures which they may contain. If, indeed, chemistry should ever attain that high degree of perfection which will enable us to discover the limits of all the possible combinations of the elementary parts of minerals, we may then subtract from our analyses those parts which do not fall within these limits, as being in mechanical admixtures, in the same manner as the chemist is now enabled to determine, from the doctrines of definite proportion alone, the quantity of uncombined acid or alkali that exists in a saline solution, when either of the ingredients is in excess.

If one class of stony bodies consists of salts, in which silex performs the functions of an acid, combining with them in definite proportions, the discovery of these proportions in the different combinations is certainly most important.

The late Dr. Clarke of Cambridge also published an arrangement of minerals purely chemical, in which the earths are considered as the oxides of metals, which cannot exist in any other state in our atmosphere. Thus barytes is an oxide of barium and silicium, zircon of zirconium and silicium, garnet an oxide of silicium, calcium, aluminum, and iron, and so on with the other genera. This system, however, has not been generally received, and indeed a more intimate acquaintance with the chemical properties of minerals than we at present possess will be necessary before any complete chemical arrangement can be formed.

Mr. Brooke, in his well known work on Crystallisation, has recommended an alphabetical arrangement of mineral substances as greatly facilitating the reference to particular specimens; and it will appear to deviate less from natural classification when we recollect that, strictly speaking, there is no natural connexion or order to supersede this method. No natural properties can determine whether zircon should be placed before or after silex, or whether lead should precede or follow iron or copper. There may be conceived to be as many natural classifications of minerals as there are physical properties common to the substances to be arranged. Thus the metals might be arranged according to their fusibility, or their ductility, or their specific gravity. Either of these characters might be adopted as the basis of a natural classification, and the order of the substances thus classed would vary according to the generic character adopted.

Acting upon these principles Mr. Brooke has given an arrangement of the mineral genera in alphabetical order, collected however into certain chemical groups, and containing accurate descriptions of the primitive forms.

In the year 1817 Dr. Brewster announced to the Royal Society the existence of what he calls a physical law, by which the primitive forms of crystallised bodies can be referred from the number of their axes of double infraction. He also asserts that every variation in the position, the intensity, and the character of these axes in smaller minerals is found to be accompanied by a difference of chemical composition; while a difference of chemical composition also denotes a difference of optical structure. All the combinations also of the sulphuric and tartaric acids with a single, earthy, alkaline, and metallic base, are found to have two axes of double refraction. In a memoir printed in the Wernerian Transactions Dr. Brewster pursued this subject to a greater length and stated that the law having been established, by a comparison of his own ex-

London, Published by Thomas Tegg, 73, Cheapside.

J. Shury sculp.

periments on polarised light with the tables of primitive forms given by the abbé Haüy, there appeared to be eleven exceptions, which were as follows:—

Sulphate of magnesia,	Cryolite,
Chromate of lead,	Harmotome,
Mesotype,	Chabasie,
Carbonate of barytes,	10 Sulphate of iron,
5 ———— strontites,	Essonite.
Iolite,	

'These exceptions, says Dr. Brewster, to a law otherwise general and comprehensive, were ascribed by myself and others to the circumstance of the primitive forms of the minerals having been erroneously determined; and as I was then aware, from actual experiment, that the optical structure of a crystal was dependent on the mechanical condition of its parts, I did not scruple to predict, and to publish the prediction, that all these eleven exceptions had their foundation in crystallographic errors, and that these minerals would be found to possess primitive forms, in perfect conformity with the general optical law which I had discovered. Crystallography and optics were thus fairly placed at issue, and there was no method of evading the decision of the mineralogists of Europe. If these eleven bodies were found to possess the primitive forms assigned to them by Haüy, the optical law which I promulgated must have instantly fallen to the ground as an imposing though imperfect generalisation, and the crystallographic method must have enjoyed the proudest triumph. The result, however, of this trial of strength was very different indeed. All the minerals out of the eleven which have been carefully re-examined by mineralogists, have been found to have different primitive forms from those assigned to them by Haüy, and in all of them has my prediction been accomplished.'

'That optical law,' continues the doctor, 'which connects the primitive forms of minerals with the number of their axes of double refraction stands pre-eminent among crystallographic generalisations, without a single ascertained exception; it has corrected the deductions of the most distinguished crystallographers of Europe; it has enabled those who confide in its accuracy to predict the results of crystallographic researches; and, what has not been sufficiently attended to, it is a law founded on experimental evidence, that the optical phenomena are the necessary results of a mechanical structure, and that their indications must infallibly harmonise with the sound deductions of crystallography. It not only decides the class of primitive forms, but it determines, which crystallography is incapable of doing, those limiting solids which form the nodes of every series of geometrical bodies. If we take a crystal, for example, bounded by six equal square faces, the crystallographer will content himself with calling it a cube; but the optical mineralogist will only call it a cube when it has no double refraction. He will maintain it to be a rhomb, if it has a single axis of double refraction, coincident with one of its diagonals; and he will consider it as a right prism with a square base, if it has a single axis of double refraction, perpendicular to any two of its faces. The position of the axis of double refraction shows, that the mechanical condition of the parts of the crystal is related to that line in which it is invariably found in every rhomboid, and in every prism with a square base.' Dr. Brewster concludes by contending that, if the physiology of mineral bodies shall ever attain to the dignity of a science, its foundations must be laid upon optical results, and its progress directed by the unerring light of optical analysis!

Of the *comparative merits* of the various systems we have described our different readers will form their ideas according to the degree in which they may have previously investigated them: while those who have never examined the subject will perhaps feel intimidated from undertaking any estimate. Into a particular or lengthened analysis of their differences our limits will not allow us to enter: a comparative sketch of their most striking features is all we can afford.

But the same reasons which require a distribution of natural science into different branches render subdivisions and arrangement in each branch peculiarly useful and important, and make necessary an acquaintance not only with the mere facts involved, but with the mutual relations that exist between them. On the basis of the whole must be established a just systematic arrangement. Such arrangements have already been successfully effected in zoology and botany; but in mineralogy difficulties arise which do not exist in classing the animal and vegetable tribes:—they make their appearance, indeed, at the very foundation of the system, viz. in forming the species. Could we satisfactorily determine what constitutes a mineral species, little difficulty would remain in forming the other divisions; but, deprived of organisation, a mineral has not the power of producing another like itself, a circumstance which, in the animal and vegetable kingdoms, is the great preservative of all the species. In bodies possessing organic structure, therefore, one species never passes into another by imperceptible degrees; whereas minerals, being formed merely by the juxtaposition of their parts, and being continually subject to the influence of external agents during the period of their formation, are frequently contaminated by foreign substances, by which different species become confounded in their appearance and properties.

It must hence be obvious that no small difficulty attends the determination of the species in mineralogy; and accordingly we find that different opinions have been entertained, and different methods employed. These however may be all comprised under the four following heads:— I. *The chemical system*, or that which is founded on a knowledge of the different elements of which minerals are composed, and the different proportions in which they are combined. II. *The mixed method*, advocated by Werner, Hoffman, and Kirwan, in which the species are determined and arranged according to the chemical and external character conjoined. III. *The external or crystallographic method*, depending

principally on the primitive crystalline forms of minerals as determined by their cleavage &c. And, IV. *The optical system*, which professes to arrange minerals according to their various powers of polarising and modifying light. Of these we certainly feel inclined to prefer a *mixed method*, similar to that of professor Cleaveland of New York, and in which the chemical character should certainly predominate. The arrangements of science, like the letters of the alphabet, may be used by children as mere objects of amusement, but are employed by men with some ultimate view, to express ideas, or to explain phenomena. In botany and zoology the objects, as they exist, are made conducive to the comfort of man; but the greater part of the mineral substances must be decomposed before they can be used by him. An arrangement having some connexion therefore with their properties *when so decomposed* must obviously be the most useful: we must in some cases rely chiefly on the external, and in others chiefly on the internal, characters; but, in all cases in which ambiguity remains, the final decision, in our view, should rest with the latter.

The chemical system, however, is not without its objections, and of these the most important appears to be the imperfection of its analysis. When the chemist determines that two bodies have the same ingredients, he is ignorant of the manner in which these ingredients are combined. If the analysis of a quadruped and a bird indicated the same elements, he could not discover that these formed horn and hair in the one, while, in the other, they displayed themselves in the finest plumage. The chemist must always fail in detecting structures, because he commences his operations by destroying them. He examines a mineral in its ruins; and after its parts have been separated, by the disintegrating power either of heat or acids, he may determine the quantity; but he is frequently ignorant of the nature of those volatile parts which escape during the destroying process. The fluoric acid, for example, in certain micas, eluded the penetration of Vauquelin, and the same gas was not discovered by Berzelius in his first analysis of apophyllite. With all the skill of modern chemistry, we are yet unable to determine which of the component parts of minerals are essential to the composition of the substance analysed, and which are but accidental mixtures. In the instance of the crystallised sandstone from Fontainbleau, no doubt can be entertained that either the carbonate of lime, or the grains of sand, must be regarded as accidental mixture, and foreign to the constitution of the species, according as we choose to consider the specimens, as arenaceous quartz agglutinated by carbonate of lime, or as carbonate of lime enclosing grains of quartz. It would, however, present little difficulty to the chemist to determine that the silex and lime are not chemically combined in the sandstone: but there are numerous other instances in which even the sagacity of a Berzelius has probably failed in discriminating the matter accidentally present in several of the species of minerals which have been analysed, from that which is essential to the composition of each particular species. In some instances the destruction of the mineral in order to analyse it cannot be allowed. Diamonds, rubies, emeralds, and other precious stones, were well distinguished by their external characters long before their internal properties were known, if even now they can be said to be so. It were indeed a melancholy circumstance for a jeweller if he had no other certain way of distinguishing his gems but by one which necessarily implies their previous destruction.

'In regard to the human intellect,' observes professor Mohs, 'the value of the information derived from natural history and from chemistry is absolutely equal. It is an erroneous idea that chemistry penetrates into the interior of bodies, and, therefore, a reprehensible practice to reproach natural history with being confined to their external appearances. It will always remain impossible to perceive the internal disposition. The analysis of a body does not disclose its interior, or its component particles, but only the exterior of the results obtained by the operations, the substances themselves, and their relations to each other. The body which has been analysed disappears, as it were, from nature; and in its stead other bodies are produced, which, as such, did not exist before. In the same manner, two or more bodies, if joined by chemical action, will disappear, and give rise to a new one, in which they no longer exist as they were before.'

It is indeed sufficiently evident that neither chemistry nor natural history can disclose the essence or interior of bodies; but surely that investigation which exhibits most of the properties for which they are valuable to man is most worthy of his attention. But chemistry alone will not suffice for the basis of a mineral arrangement; for unless we could again recognise, by its external character, a species already analysed, each individual must be destroyed to discover its place in the system. To unite the two systems seems, therefore, the most advisable plan.

Concerning the prevailing system of M. Mohs we fear, however, that we entertain very heretical opinions. We object to the undue prominence given in this system to crystallography; which, as very many important classes of minerals, as coal, chalk, slate, &c., are destitute of crystalline structure, can never be of universal application. The destruction, even of a crystallised unknown species, is equally necessary to discover its primitive form, as to complete its chemical analysis; and, when we take into consideration the frequent occurrence of isomorphous crystals, little more accuracy can be claimed for one mode than for the other. 'It demands,' observes Mr. Brooke, 'great precision of hand and eye to obtain the true measurements of angles to a minute only, and we cannot say that a difference of species may not exist, with a difference of only a few seconds in the angles of inclination of their planes. We know that the greater angle of a right rhombic prism must lie somewhere between 90° and 180°. If the angle were 90°, the prism would be square, and 180° would reduce the prism to a plane. But, between 90° and 180°, we do not know how many dif-

ferent prisms may exist. If they differed by degrees only, their number could exceed eighty-nine. If the difference consisted of minutes, there might be 5399 such prisms, all distinguishable by the goniometer; but, if the differences consisted of seconds only, there might evidently be 323,999 rhombic prisms, of which no more than 5399 could be distinguished by the ordinary goniometric instruments.' We object again to that vagueness of definition which can allow the introduction of atmospheralia into a mineral arrangement, and the collection of earthy and metalliferous minerals into one class merely because their specific gravity is above 1·8. From M. Mohs's definition it is really impossible to understand what simple minerals are. Porcelain, earth, and green earth, are rejected because chemistry, whose assistance the professor seems to despise, has discovered them to be decompositions of felspar and talc-mica. Iron-flint, heliotrope, jasper, tile-ore, clay, tripoli, yellow earth, and many others, are considered to be mixtures as much as granite, though the component particles are undistinguishable, by reason of their smallness. Hence no one of them is treated even as a particular species in his arrangement of the mineral kingdom. Basalt, claystone, serpentine, &c., are likewise held to be mixtures.

In the mean time water and atmospheric air are ranked as simple minerals, although certainly chemical compounds; and the interference of the chemist is deprecated, though the system is founded upon the results of his labors. If hydrogen be included among minerals, merely because it is produced by the earth in certain places, then with equal propriety may oxygen be arranged among the plants, because produced by them naturally and constantly. 'Surely this system,' to adopt a favorite phrase of professor Mohs's, 'carries with it its own refutation.' Yet it should be observed, that the professor considers the application of his ideas 'too confined, if we consider as natural productions only those bodies for which nature itself has produced the essential circumstances and causes of formation. A number of salts, and other bodies, obtained by the aid of chemistry, would in that case be excluded, and considered as artificial productions, although the part which art, or the control of man, takes in their formation, is entirely limited to the mere production of those circumstances under which nature may exert, in producing those new combinations, the same powers which enter into action when the other bodies are produced.' We need only observe that the same arguments would reduce the whole of chemical philosophy, and even caloric and light, within the scope of professor Mohs's mineral kingdom. We cannot better conclude these remarks on the external system than by the following queries of professor Cleveland:—

'Can similarity of color,' says he, 'or of form, fracture, hardness, &c., constitute a resemblance so perfect, as that which arises from identity of composition? Or can a difference of color, form, fracture, &c., establish so important a distinction between minerals, as that which is produced by dissimilarity of composition? Would not two minerals, both composed of phosphoric acid and oxide of lead, in the same proportion, belong to the same species, although the color of one should be brown, and that of the other green? Would not two minerals, composed of phosphoric acid and lime, in the same proportion, belong to the same species, although the forms of their crystals, essentially the same, should exhibit different modifications? In fine, can properties liable to numerous variations, from trivial and accidental causes, be supposed to establish the identity of two or more minerals with that degree of evidence which is afforded by a well ascertained similarity in composition? We hesitate not to answer these questions by saying, that the true composition of minerals ought to be the basis of arrangement; and by this ought the species to be established. The composition of a mineral, that is, the ingredients proper and essential to its composition, may remain unaffected by the accidental presence of certain foreign ingredients, which materially change several of the external characters.'

The optical system of Dr. Brewster has been before the public so short a time that no final opinion can be given as to its merits. He appears to have examined a very considerable number of mineral and other bodies by means of polarised light, and has been led by this examination to the following optical classification of crystals:—1st. Those in which only one axis of double refraction has been yet observed; which include nearly all the crystals comprised in the first and second of Mohs's systems. 2dly, Those which possess two axes, consisting of nearly, if not entirely, the whole of Mohs's third system. But some, which crystallographically belong to the first and second systems, are also included by Dr. Brewster in this. 3dly, Those in which no double refraction has been yet discovered, either by direct experiment, or by means of polarised light, and which belong to the fourth system of Mohs.

Out of these facts, which, we must allow, are very numerous, and hence very imposing, Dr. Brewster has produced two optical systems; one relating to mineralogy generally; and the other relating to compounds of sulphuric and tartaric acids, with earthy, alkaline, and metallic bases, all of which are said to have two or more axes of double refraction. But in the Philosophical Transactions for 1816, Dr. Brewster announces the discovery, that *muriate of soda, fluor-spar* and *diamond*, which belong to the *tessular system* of Mohs, and hence ought to possess *no double refraction*, may receive that property by *compression or dilatation*. And, in the volumes for 1816 and 1818, it is stated, *that all the properties of regular crystals might be communicated permanently to glass, and other crystallised bodies, by heat.* This completely, in our humble estimate, overturns the basis of the system. If optical phenomena are to constitute specific characters among minerals, does it not follow either that glass changes its species with its change of optical character, or that optical characters are insufficient to distinguish species? We fear we must conclude with Mr. Brooke, 'that the connexion between the optical characters of minerals and

their crystalline forms is not yet sufficiently understood to make it available for mineralogical purposes.

PART III.

THE ARRANGEMENT OF KNOWN MINERAL SUBSTANCES.

The description of minerals, and their arrangement in systematic order, seem most naturally to result from an investigation of certain relations which minerals bear to our senses, or to other objects. Some of these are discoverable by mere inspection, or, at most, require some simple experiment to be made upon the mineral to ascertain its hardness, structure, &c., but without producing any important change in its natural state; while others cannot be observed without a partial or complete decomposition of the mineral. All these properties, when employed for the purpose of discriminating minerals, are usually called characters, and are as follows:—

General Characters.

The general characters are, color, cohesion, unctuosity, coldness, weight, smell, taste.

Color.—The colors of minerals are distinguished into fundamental and compound. Fundamental colors are eight in number; namely, snow-white, as Carrara marble; ash-gray, as wacken; velvet-black, as jet; Berlin or Prussian blue, as sapphire; emerald-green, as fluor spar; lemon-yellow, as in yellow orpiment; carmine-red, as in cinnabar. Chestnut brown, the color of the ripe chestnut.

Compound colors are, 1. Of the whites, reddish-white, or snow-white mixed with a crimson-red, as porcelain; yellowish-white, or snow-white with a lemon-yellow, as white amber; silver-white or grayish-white, as silver; greenish-white, or snow-white mixed with a little emerald-green, and ash-gray, as gypsum, quartz, &c.; milk-white, or snow-white, with a little Berlin and ash-gray, as chalcedony. 2. Of the grays, the lead-gray, or ash-gray, with a little blue metallic lustre, as galena; bluish-gray, or ash-gray, with a little blue, as bluish gray clay; smoke-gray, or ash-gray, with a little brown, as gray-hornstone; pearl-gray, i.e. gray with a little crimson-red and blue, as quartz; greenish-gray, i.e. with a little emerald-green, and sometimes a trace of yellow, as in cat's-eye, prehnite, &c.; yellowish-gray, i.e. with lemon-yellow and a trace of brown, as yellowish-gray chalcedony; steel-gray, i.e. gray with a little blue and a metallic lustre, as gray copper ore. 3. Of blacks, the grayish-black, or velvet-black, with a little ash-gray, as in basalt; iron-black, darker than the preceding, with a metallic lustre, as in magnetic iron-stone; pitch-black, with a little brown and yellow, as pitch-stone; raven-black, with a little brown, yellow, and green, as in black blende; bluish-black, as in black cobalt. 4. Of blues, the indigo blue, or Berlin blue, with a little black, as in blue martial earth; azure-blue, with a little red, as in lapis lazuli; violet-blue, with much red, and a little brown, as in fluor spar and amethyst, &c.; lavender blue, with a little gray, as in jasper; smalt-blue, with white, a little gray, and a trace of red, as in azure copper ore; sky-blue, as in blue fluor spar. 5. Of greens, the verdigris-green, of emerald-green, with much Berlin blue, and a little white, as in green copper ore: mountain-green, with a little yellowish gray, as in actynolite; apple-green, with a little grayish-white, as in chrysolite; grass-green, with a little lemon-yellow, as in chrysoprase; blackish-green, with a considerable portion of black, as in green serpentine; pistachio-green, with a little yellow and brown, as in chrysolite; asparagus green, with a little grayish-white, as in chryso-beryl; olive-green, with much brown, as in garnet; siskin-green, with much lemon-yellow, and a little white, as in green lead ore. 6. Of yellows, the sulphur-yellow, or lemon-yellow, with much emerald green and white, as in native sulphur; gold-yellow, straw-yellow, with much grayish-white, as in calamine and bismuth ochre; honey-yellow, with chestnut-brown; wax-yellow, i.e. reddish-brown, with a little ash-gray, as in common opal; ochre-yellow, with much chestnut-brown, as in iron ochre, calamine, &c.; orange-yellow, with a little carmine-red, as in red orpiment; brass-yellow, with the metallic lustre, as copper pyrites; cream color, or Isabella-yellow, with grayish-white, and a little brown and red, as in sparry iron ore; wine-yellow, with reddish, brown, and gray, as yellow calcareous spar. 7. Of reds, the aurora-red, or carmine-red, mixed with much lemon-yellow, as in red orpiment; hyacinth-red with lemon-yellow, and a little brown, as in the hyacinth, and in brown blende; brick-red, with much grayish-white, as in porcelain jasper; scarlet-red, with a very little lemon-yellow, as in red cinnabar; copper-red, as in native copper; blood-red, scarlet-red mixed with brownish-black, as in Bohemian garnet; cochineal-red, carmine-red mixed with bluish-gray, as in cinnabar; crimson-red with much blue, as in ruby; columbine-red, with more blue, and a little black, as in red cobalt ore; flesh-red with grayish white, as in felspar; rose-red, cochineal-red mixed with white, as in red zeolite; peach-blossom-red, crimson-red mixed with white, as in striated and earthy red cobalt ores; cherry-red, crimson-red mixed with much brownish-black, as in red argillaceous iron-stone; brownish-red, blood-red mixed with brown, as in red earthy iron-stone 8. Of browns, the chestnut-brown, mixed with a little red and yellow, as in brown tin ore; clove-brown, with cochineal-red and a little black, as in rock crystal; hair-brown, clove-brown mixed with ash-gray, as in wood-tin ore from Cornwall; yellowish-brown, chestnut-brown with a considerable portion of lemon-yellow, as in brown iron ochre and jasper; pinchbeck-brown with the metallic lustre, as brown mica; wood-brown, yellowish-brown with much ash-gray, as in bituminous wood; liver-brown, as in brown cobalt ore; blackish-brown, chestnut-brown and black, as in mineral pitch.

In respect to *intensity*, colors are either dark, deep, or light; or they are said to incline to one another, or to pass into one another; and, when they lose their original color, to be tarnished. When different colors appear in the same mineral,

they may be disposed in clouds, dots, streaks, rings, veins, zones. &c.

Cohesion.—In respect to cohesion minerals are either solid, friable, or fluid.

Unctuosity.—In respect to unctuosity they are either greasy or meagre.

Coldness, &c.—In respect to coldness they vary only in degree; and in respect to smell and taste the distinctions are too obvious to need description.

Weight.—The weight of minerals is accurately discovered by taking the specific gravity by means of a hydrostatic balance.

Specific gravity.—The specific gravity of a body is its weight, compared with that of another body of like magnitude. The usual standard employed is distilled water, 1 cubic foot of which weighs 1000 ounces avoirdupois. This may be called 1000, or 100, or 10, or 1, adding decimals. If we assume 1 as the standard, then, as the weight which a body loses in water is to its absolute weight, so is 1 to the specific gravity required. If the mineral be lighter than water, add the weight which is necessary to sink it in water to its weight in air; and say, as the sum is to its weight in air, so is air to its specific gravity.

On this principle is founded the method of taking specific gravities by the instrument commonly called Nicholson's Portable Balance. The body of this instrument is a hollow cylinder of tinned iron, of which each extremity terminates in a cone. From the vertex of the upper cone a small stem of brass rises perpendicularly, bearing on its upper extremity a small tin cup. From the vertex of the lower cone is suspended a similar cup, attached to a cone of lead underneath it as a ballast. Both the cups may be removed, when the balance is not in use. When this instrument is placed in a vessel of water, a portion of the cylinder ought to swim above the surface. The tin cup is then to be loaded with weights, till the instrument sinks so far that the surface of the water may exactly coincide with a mark on the brass stem. The quantity necessary to make the instrument sink thus far may be marked on the cup, as a given quantity for future use.

Suppose this quantity to be 600 grains, which may be called the balance weight, and will serve for taking the specific gravity of any substance, whose absolute weight is not greater than that of the balance weight. To ascertain the specific gravity of a mineral, place it alone in the upper cup, and add weights, till the mark on the stem coincides with the surface of the water; and suppose this to be 210 grains. Subtract the 210 grains from the balance weight of 600 grains; and the remaining 390 grains is the absolute weight of the mineral in air. Let the mineral be now removed to the lower cup; but, as it weighs less in water than in air, the mark on the stem will rise a little above the surface of the water. Additional weights must now be placed in the upper cup, till the mark on the stem again coincides with the surface of the water. Suppose this to be eighty grains, which will of course be the weight of a quantity of water precisely equal in bulk to the mineral. We now have the absolute weights of equal bulks of water and of the mineral; then say, as 80 : 390 : : 1000 : 4875, the specific gravity.

If the mineral under examination be lighter than water, it must be confined, when weighed in the lower cup; and the weight of whatever confines it is to be regarded as belonging to that of the instrument. In other respects the process is the same as the preceding.

If the mineral very sensibly absorb water, the weight of the water imbibed must be ascertained by again weighing the mineral in air; and is then to be added to the first term of the proportion.

Particular Characters.

The particular characters comprehend the general aspect, aspect of the surface, aspect of the cleavage, aspect of the distinct concretions, hardness, and adhesion to the tongue.

General aspect.—Under the general aspect are comprehended the transparency, streak, and soiling.

In respect to transparency, minerals are said to be transparent when objects can be seen distinctly through them; semitransparent when seen indistinctly through them; translucent when light passes through them, but not in such quantity that objects may be discerned through them; opaque when no light is transmitted; hydrophanous when opaque minerals become transparent in water. When objects are seen double through a transparent mineral they are said to refract doubly. The streak, or scratch, is the mark left by the scratching a mineral, which is termed similar if it be of the same color as the mineral, or dissimilar if of a different color. Soiling is the stain which some minerals leave when rubbed on the fingers, or on paper.

Aspect of the surface.—To the aspect of the fracture belong the shape of the mineral, the kind of surface, and the lustre of the surface. The external shape is common when it is too irregular to be compared, in respect to form, with any other body, as when it composes the part of a solid rock, and is called massive; or when it is very small, and is said to be disseminated. When it occurs loose it is either in angular pieces, in grains, in plates, or in membranes. The external shape is denominated particular when it may be compared with that of any other body. Of this description are the dentiform, filiform, capillary, globular, reniform, cellular, amorphous, vesicular, &c., whereby is indicated the body which the mineral resembles in shape. The shape of minerals is moreover denominated regular when they occur in a crystallised state (vide Crystallisation and Chemistry); and extraneous when they are of the nature of petrifactions. The external surface of minerals is uneven when it has small unequal elevations and depressions; granulated when composed of small round elevations, like shagreen: rough when the elevations felt are too small to be distinctly seen; smooth, as in the hæmatites; streaked, as in rock crystals, &c.; and drusy when coated with small crystals, as the quartz. External lustre is of two

kinds, common and metallic; the latter of which is subdivided into semimetallic, adamantine, pearly, resinous, and glassy. In point of intensity, the lustre is splendent when it may be seen at a great distance in the daylight; shining when the light is reflected weakly at a distance; glistening when the lustre is visible at no greater distance than an arm's length; glimmering when the surface held near in full daylight presents a number of shining points; dull when the surface has no lustre.

Aspect of the cleavage.—Cleavage is the property which minerals possess of splitting in certain determinate directions. The faces or planes thus obtained, which are termed the faces of the cleavage, are more or less smooth and shining. The forms contained under these faces are called forms of cleavage, or cleavage forms.

The cleavage-forms represent members of the series of crystallisation of those mineral species to which the mineral having the cleavage belongs. The same may be inferred of such individuals or species as possess more than any cleavage form. Hence cleavage extends the application of crystallography in the mineral kingdom, because a mineral, although it be not crystallised, may be cleavable, and thus allow the series, at least the system of crystallisation, to be made out by cleavage in most of the cases, where no regular crystallisations occur.

The cleavage forms are designated like those of crystallisation. Cleavage-forms, Mohs remarks, if among the number of those which in the preceding pages served as a basis to the derivation, are by preference chosen for representing the fundamental form in the species to which they belong; as in rhomboidal calc-spar, the rhomboid of 105° 5′. This rule, however, suffers an exception in the case of a rhomboid or a pyramid, which occur as cleavage-forms, being too obtuse or too acute. For this reason, in pyramidal copper pyrites, the fundamental form is P, though the cleavage form is P+1. No cleavage form whose dimensions are infinite can be employed as a fundamental form.

Hardness.—The degrees of hardness or their limits are by Kirwan, Mohs, and others expressed by numbers. The most precise scale of hardness is that of Mohs, in which the degrees are determined according to the following scale:—

1. Denotes the degree of hardness of common talc and Venetian talc.
2. Is the hardness of a variety of prismatoidal gypsum, with an imperfect cleavage and imperfect transparency. Varieties perfectly transparent and crystallised are commonly too soft.
3. Hardness of a cleavable variety of calcareous spar.
4. Hardness of fluor spar.
5. Hardness of apatite.
6. Hardness of prismatic felspar.
7. Hardness of rhomboidal quartz.
8. Hardness of prismatic topaz.
9. Hardness of rhomboidal corundum.
10. Hardness of octahedral diamond.

Adhesion to the tongue.—This property in minerals varies in the degrees of strong, rather strong, weak, and very weak. Some admit of no adhesion.

The above-mentioned properties are all comprehended under the general name of external characters, in distinction from the physical and chemical characters by which some minerals are known.

Physical Characters.

The most common and obvious of the physical characters is the electrical property which some minerals possess. Some minerals become electric when heated, others when rubbed. The electricity thus excited is in some positive or vitreous; in others it is negative or resinous. The magnetic property of some minerals, particularly of the iron ores, is well known, as also the phosphorescent property of others, particularly the varieties of the blende. To the Lemnian earth, and other boles, belong the peculiar property of making a crackling noise when split and thrown into water; and other minerals have particular properties by which they might be sufficiently distinguished.

Chemical Characters.

By chemical experiments the nature of many mineral substances may be easily and quickly ascertained. The fusibility of many minerals is determined by the blow-pipe. The effervescing property of some bodies is determined by means of acids, particularly nitrous acid. Ammonia, or the volatile alkali, dissolves copper, and assumes a blue color; acetic acid is employed as a test of lead, by its communicating to the acid a sweetish taste. In this manner discriminating characters are derived from the chemical properties of minerals, which may answer the purpose of classification in many cases full as well as the external characters.

Of the analysis of earths and stones.—When any of these substances are to be tried, we must not begin immediately with the blow-pipe; till some preliminary experiments be made, by which those in the fire may afterwards be directed. For instance, a stone is not always homogeneous, or of the same kind throughout, although it may appear to be so. A magnifying glass is therefore necessary to discover the heterogeneous particles, if there be any; and these ought to be separated, and every part tried by itself. This might happen with some of the finer micæ, which are now and then found mixed with small particles of quartz, scarcely to be perceived by the eye. The trapp (German schwartzstein) is also sometimes mixed with very fine particles of feldt spar (spatum scintillans), or of calcareous spar, &c.

After this experiment the hardness of the stone must be tried with steel. The flint and garnets are known to strike fire with steel; but there are also other stones, which are so hard as likewise to strike fire. There is a kind of trapp of that hardness, in which no particles of feldt spar are to be seen. Colored glasses resemble true gems; but, as they are very soft in proportion to these, they are easily discovered by the file. The common quartz crystals are harder than colored

glasses, but softer than gems. The loadstone discovers the presence of iron, when it is not mixed in too small a quantity in the stone, and often before the stone is roasted. Some kinds of hæmatites, and particularly the cœrulescens, greatly resemble some other iron ores; but this is distinguished from them by a red color when pounded, the others giving a blackish powder.

The management of the BLOW-PIPE is described under that article; but a few particulars must be here added.

The blue flame is the hottest; this ought, therefore, to be forced out when a great heat is required; and only the point of the flame must be directed upon the subject which is to be assayed. Its upper end must be bended towards the matter intended to be heated, and the stream of air must be directed along the surface of the bended part, so as not absolutely to touch it.

The piece of charcoal made use of in these experiments must not be apt to crack. If this should happen it must gradually be heated until it does not crack any more, before any assay is made upon it. If this be not attended to, but the assay made immediately with a strong flame, small pieces of it will split off in the face and eyes of the assayer, and often throw along with them the matter that was to be assayed. Charcoal which is too much burnt consumes too quick during the experiment, leaving small holes in it, wherein the matter to be tried may be lost; and charcoal that is burnt too little catches flame from the candle, burning by itself like a piece of wood, which likewise hinders the process.

Of the substance to be assayed, only a small piece must be broken off, not bigger than that the flame of the candle may be able to act upon it at once, if required; which is sometimes necessary, as when the matter requires to be made red-hot throughout, the piece ought to be broken as thin as possible; the fire having then more influence upon the subject, and the experiment being more quickly made.

Some mineral bodies are very difficult to be kept steady upon the charcoal during the experiment, before they are made red-hot; because, as soon as the flame begins to act upon them, they split asunder with violence, and are dispersed. Such are, for instance, the calcareous spar, the sparry gypsum, sparry fluor, white sparry lead ore, the potter's ore, the tessellated mock lead or blende, &c., and all the common fluors which have no determinate figure. These not being so compact as common hard stones, when the flame is immediately urged upon them, the heat forces into their clefts or pores, and causes this violent expansion and dispersion. Many clays are likewise apt to crack in the fire, which is mostly owing to the humidity, of which they always retain a portion.

The only way to prevent this inconvenience is to heat the body as slowly as possible. First heat that place of the charcoal where the piece is intended to be put, and afterwards lay it thereon: a little crackling will then ensue, but commonly of no great consequence. The flame is then to be blown very slowly towards it, in the beginning not directly upon, but somewhat above it, and so approaching nearer and nearer with the flame until it become red-hot. This will do for the most part; but there are nevertheless some, which, notwithstanding all these precautions, it is almost impossible to keep on the charcoal. Thus the fluors are generally the most difficult; and as one of their principal characters is discovered by their effects in the fire per se, they ought necessarily to be tried that way. For this purpose it is best to make a little hole in the charcoal to put the fluor in, and then to put another piece of charcoal as a covering upon this, leaving only a small opening for the flame to enter. As this stone will nevertheless split and fly about, a large piece thereof must be taken, in order to have something of it left. But, if the experiment is to be made upon a stone with fluxes, then a piece of it ought to be forced down into melted borax, when always some part of it will remain in the borax, notwithstanding the greatest part may sometimes fly away by cracking.

As the stones undergo great alterations when exposed to the fire by themselves, whereby some of their characteristics, and often the principal, are discovered, they ought first to be tried that way. The following are generally the results of this experiment:

Calcareous earth or stone, when pure, does not melt by itself, but becomes white and friable, so as to break freely between the fingers; and if suffered to cool, and then mixed with water, it becomes hot, like quicklime. As in these experiments only very small pieces are used, this last effect is best discovered by putting the proof on the outside of the hand, with a drop of water to it, when instantly a very quick heat is felt on the skin. When the calcareous substance is mixed with the vitriolic acid, as in gypsum, or with a clay, as in marl, it commonly melts by itself, yet with more or less difficulty in proportion to the differences of the mixtures. Gypsum produces generally a white, and marl a gray, glass or slag. When there is any iron in it, as a white iron ore, it becomes dark, and sometimes quite black, &c.

The siliceæ never melt alone, but become generally more brittle after being burnt. Such of them as are colored become colorless, and the sooner when it does not arise from any contained metal; for instance, the topazes, amethysts, &c., some of the precious stones, however, excepted; and such as are mixed with iron grow dark in the fire, as some of the jaspers, &c.

The garnets melt always into a black slag, and sometimes so easily that they may be brought into a round globule upon the charcoal.

The argillaceæ, when pure, never melt, but become white and hard. The soap-rock is easily cut with a knife; but, being burnt, it cuts glass, and would strike fire with steel, if as large a piece as is necessary for that purpose could be tried in this way. The soap rocks are sometimes found of a dark brown, and nearly black color, but nevertheless become quite white in the fire. But care must be taken not to urge the flame from the top of the wick, there being for the most part a sooty smoke, which will darken all that it touches; and, if this be not observed, a mistake in the experiment may happen. But if it is mixed with

iron, as it sometimes is, it does not so easily part with its dark color. The argillaceæ, when mixed with lime, melt by themselves. When mixed with iron, as in the boles, they grow dark or black; and, if the iron is not in too great a quantity, they melt alone into a dark slag; the same happens when they are mixed with iron and the vitriolic acid, as in the common clay, &c.

Mica and asbestos become somewhat hard and brittle in the fire, and are more or less refractory, though they give some marks of fusibility.

The fluors discover one of their chief characteristics by giving a light like phosphorus in the dark, when they are slowly heated; but lose this property, as well as their color, as soon as they are made red hot. They commonly melt in the fire into a white opaque slag, though some of them not very easily.

Some sorts of the zeolites melt easily, and foam in the fire, sometimes nearly as much as borax, and become a frothy slag, &c.

Many of those mineral bodies which are impregnated with iron, as the boles, and some of the white iron ores, &c., as well as some of the other iron ores, viz. the bloodstone, are not attracted by the loadstone before they have been thoroughly roasted, &c.

After the minerals have been tried in the fire by themselves, they ought to be heated with fluxes, to discover if they can be melted or not, with some other phenomena attending this operation. For this purpose, three different kinds of salts are used as fluxes, viz. soda, borax, and sal fusibile microcosmicum. See FLUX.

The soda is, however, not much used in these small experiments, its effects upon the charcoal rendering it, for the most part, unfit for it; because, as soon as the flame begins to act upon it, it melts instantly, and is almost wholly absorbed by the charcoal. When this salt is employed to make any experiment, a very little quantity is wanted at once, viz. about the cubical contents of an eighth part of an inch. This is laid upon the charcoal, and the flame blown on it with the blow-pipe; but, as this salt commonly is in form of a powder, it is necessary to go on very gently, that the force of the flame may not disperse the minute particles of the salt. As soon as it begins to melt, it runs along on the charcoal, almost like melted tallow; and when cold it is a glassy matter, of an opaque dull color, spread on the coal. The moment it is melted, the matter which is to be tried ought to be put into it, as otherwise the greatest part of the salt will be soaked into the charcoal, and too little of it left for the intended purpose. The flame ought then to be directed on the matter itself; and if the salt spreads too much about, leaving the proof almost alone, it may be brought to it again by blowing the flame on its extremities, and directing it towards the subject of the experiment. In the assays made with this salt, we may find whether the mineral bodies which are melted with it have been dissolved by it or not; but we cannot tell with any certainty whether this is done hastily and with force, or gently and slow; nor whether a less or a greater part of the matter has been dissolved; neither can it be well distinguished if the matter has imparted any weak tincture to the slag; because this salt always bubbles upon the charcoal during the experiment, nor is it clear when cool; so that scarcely any color, except a very deep one, can be discovered; although it may sometimes be colored by the matter that has been tried.

In the following lists, the articles marked † effervesce very little; those marked ‡ not at all; those marked * require a larger quantity of the flux and a longer continuance of heat than the rest; those marked || are more difficultly dissolved than the others.

The following earths are entirely soluble in soda, with effervescence:—agate, chalcedony, carnelian, Turkey stone †, fluor minerals †, onyx, opal, quartz, common flint, ponderous spar. The following are divisible in it, with or without effervescence, but not entirely soluble:—amianthus, asbestos, basaltes, chrysolite ‡, granate ‡, horn-blende, jasper, marl-stone, mica, the mineral of alum from Tolfa, petrosilex, aluminous slate and roof-slate from Helsingia, emeralds, steatites, common flint, schorl, talc, trapp, tripoli, tourmalin. And the following are neither fusible nor divisible in it:—diamond, hyacinth, ruby, sapphire, topaz.

The other two salts, viz. borax and the sal microcosmicum, are very well adapted to these experiments, because they may by the flame be brought to a clear, uncolored, and transparent glass; and, as they have no attraction to the charcoal, they keep themselves always upon it in a round globular form. The sal fusibile microcosmicum is very scarce; it is made of urine.

The following earths are soluble in borax, with more or less effervescence:—Fluor minerals †, marl, mica † the mineral of alum from Tolfa, aluminous slate and roof-slate from Helsingia †, ponderous spar, schorl, talc †, tourmalin. And the following without effervescence:—Agate, diamond, amianthus, asbestus, basaltes, chalcedony, carnelian, chrysolite, Turkey-stone, granate, hyacinth *, jasper, lapis ponderosus, onyx, opal, petrosilex, quartz *, ruby, sapphire, common flint *, steatites, trapp, trippel, or tripoli topaz, zeolite, hydrophanes.

In the microcosmic salt, the following are soluble, with more or less effervescence:—Basaltes †, Turkey-stone ‡, fluor mineralis †, marl, mica, the mineral of alum from Tolfa, schistus aluminaris, schistus tegularis from Helsingia †, schorl, spathum ponderosum, tourmalin †, lapis ponderosus; and the following without visible effervescence:—Agate, diamond, amianthus, asbestus, chalcedony, carnelian, chrysolite, granate, hyacinth, jasper, onyx ||, opal, petrosilex, quartz ||, ruby, sapphire, common flint ||, emerald, talc, topaz, trapp, trippel, zeolite, horn-blende, hydrophanes, lithomarga, steatites.

Calcareous earth, ponderous spar, gypsum, and other additaments, often assist the solution both in the microcosmic salt and in borax. To observe the effervescence properly, the matter added to the flux should be in the form of a small particle rather than in fine powder; because in this last there is always air between the particles, which, being afterwards driven off by the heat, afford the appearance of a kind of effervescence

The quantity of these two salts required for an experiment is almost the same as the soda; but as the former are crystallised, and consequently include a great deal of water, particularly the borax, their bulk is considerably reduced when melted, and therefore a little more of them may be taken.

Both these salts, especially the borax, when exposed to the flame of the blow-pipe, bubble very much, and foam, before they melt to a clear glass, which for the most part depends on the water they contain. And as this would hinder the assayer from making due observations on the phenomena of the experiment, the salt which is to be used must first be brought to a clear glass, before it can serve as a flux; it must, therefore, be kept in the fire until it become so transparent that the cracks in the charcoal may be seen through it. This done, whatsoever is to be tried is put to it, and the fire continued.

For the assays made with any of these two fluxes on mineral bodies, no larger pieces must be taken than that altogether they may keep a globular form upon the charcoal; as it may then be better distinguished in what manner the flux acts upon the matter during the experiment. If this be not observed, the flux, communicating itself with every point of the surface of the mineral body, spreads all over it, and keeps the form of this last, which commonly is flat, and thus hinders the operator from observing all the phenomena. Besides, the flux being in too small a quantity, in proportion to the body to be tried, will be too weak to act with all its force upon it. The best proportion, therefore, is about a third part of the mineral to the flux; and as the quantity of the flux above mentioned makes a globe of a due size, in regard to the greatest heat that is possible to procure in these experiments, so the size of the mineral must be a third part less here than when it is to be tried in the fire by itself. Soda is not of much use in these experiments; nor has it any particular qualities, in preference to the two last-mentioned salts, except that it dissolves the zeolites easier.

The microcosmic salt shows almost the same effects in the fire as the borax, only differing from it in a very few circumstances; of which one of the principal is, that, when melted with manganese, it becomes of a crimson hue, instead of a jacinth color, which borax takes. This salt is, however, from its scarcity, still very little in use, borax being commonly employed. Whenever a mineral body is melted with any of these two salts, it is easily seen, whether it quickly dissolves; in which case an effervescence arises, that lasts till the whole be dissolved; whether the solution be slowly performed, in which case few and small bubbles only rise from the matter; or, whether it can be dissolved at all; because, if not, it is observed only to turn round in the flux, without the least bubble, and the edges look as sharp as before.

To illustrate farther these experiments, we shall give a few examples of the effects of borax upon the mineral bodies. The calcareous substances, and all those stones which contain lime, dissolve readily and with effervescence in the borax. The effervescence is the more violent, the greater the portion of the lime contained in the stone. This cause, however, is not the only one in the gypsum, because both the constituents of this readily mix with the borax, and therefore a greater effervescence arises in melting gypsum with the borax than lime alone. The siliceæ do not dissolve, some few excepted, which contain a quantity of iron. The argillaceæ, when pure, are not acted upon by the borax; but, when mixed with some heterogeneous bodies, they are dissolved, though very slowly; such are the stone marrow, common clay, &c. The granates, zeolites, and trapp, dissolve but slowly. The fluors, asbestinæ, micaceæ, dissolve for the most part very easily. Some of these bodies melt to a colorless transparent glass with the borax; for instance, the calcareous substances, when pure, the fluors, some of the zeolites, &c. Others tinge the borax with a green transparent color, viz. the granates, trapp, some of the argillaceæ, and some of the micaceæ and asbestinæ.

Borax can only dissolve a certain proportional quantity of the mineral. Of the calcareous kind it dissolves a vast quantity; but turns at last, when too much has been added, from a clear transparent to a white opaque slag. When the quantity of the calcareous matter exceeds but little in proportion, the glass looks very clear as long as it remains hot; but, as soon as it begins to cool, a white half-opaque cloud is seen to arise from the bottom, which spreads over the third, half, or more of the glass globe, in proportion to the quantity of calcareous matter; but the glass or slag is nevertheless shining, and of a glassy texture when broken. If more of this matter be added, the cloud rises quicker and is more opaque, and so by degrees till the slag becomes quite milk white. It is then no more of a shining, but rather dry appearance on the surface; is very brittle, and of a grained texture when broken.

Of the analysis of metals and ores.—In examining metals and ores an exact knowledge and nicety of procedure are the more necessary, that the metals are often so disguised in their ores, as to be very difficultly known by their external appearance, and liable sometimes to be mistaken one for the other:—some of the cobalt ores, for instance, resemble much the pyrites arsenicalis; there are also some iron and lead ores which are very like one another, &c.

As the ores generally consist of metals mineralised with sulphur or arsenic, or sometimes both, they ought first to be exposed to the fire by themselves, not only to determine with which of these they are mineralised, but also to set them free from those volatile mineralising bodies: this serves instead of calcination, by which they are prepared for further assays. Whenever any metal or fusible ore is to be tried, a little concavity must be made in that part of the charcoal where the matter is to be put; to prevent it from rolling off. When an ore is to be tried, a small bit is laid upon the charcoal, and the flame blown on it slowly. Then the sulphur or arsenic begins to part from it in form of smoke; these are easily distinguished by their smell; that of sulphur being sufficiently known, and the arsenic smelling like garlick. The flame ought to be

blown very gently as long as any smoke is seen to part from the ore; but, after that, the heat must be augmented by degrees, to make the calcination as perfect as possible. If the heat be applied very strongly from the beginning, upon an ore that contains much sulphur or arsenic, the ore will presently melt, and yet lose very little of its mineralising bodies; thus rendering the calcination very imperfect. It is, however, impossible to calcine the ores in this manner to the utmost perfection, which is easily seen in melting down a calcined potter's ore with borax, as it will bubble upon the coal, which depends on the sulphur still left, the vitriolic acid of this uniting with the borax, and causing this motion. However, lead in its metallic form, melted in this manner, bubbles upon the charcoal, if any sulphur remains in it. But as the lead, as well as some of the other metals, may raise bubbles upon the charcoal although they are quite free from the sulphur, only by the flames being forced too violently on it, these phenomena ought not to be confounded with each other.

The ores being thus calcined, the metals contained in them may be discovered, either by being melted alone or with fluxes; when they show themselves, either in their pure metallic state or by tinging the slag with a color peculiar to each of them. In these experiments it is not to be expected that the quantity of metal contained in the ore should be exactly determined; this must be done in larger laboratories. This cannot, however, be looked upon as any defect, since it is sufficient for a mineralogist to find out what sort of metal is contained in the ore. There is another and a more real defect in the miniature laboratories, viz. that some ores are not at all capable of being tried by so small an apparatus; for instance, the gold ore called pyrites aureus, which consists of gold, iron, and sulphur. The greatest quantity of gold which this ore contains is about one ounce, or one ounce and a half, out of 100 pounds of the ore, the rest being iron and sulphur: and, as only a very small oit is allowed for these experiments, the gold contained therein can hardly be discerned by the eye, even if it could be extracted; but it goes along with the iron in the slag, this last metal being in so large a quantity in proportion to the other, and both of them having an attraction for each other.

The blendes and black jacks, which are mineral zinc ores, containing zinc, sulphur, and iron, cannot be tried this way, because they cannot be perfectly calcined, and besides the zinc flies off when the iron scorifies. Neither can those blendes which contain silver or gold, mineralised with them, be tried in this manner, which is particularly owing to the imperfect calcination. Nor are the quicksilver ores fit for these experiments; the volatility of that metal making it impossible to bring it out of the poorer sort of ores; and the rich ores, which sweat out the quicksilver when kept close in the hand, not requiring any of these assays. These ores ought to be assayed in larger quantities, and by such other methods as cannot be used upon a piece of charcoal. Some of the rich silver ores are easily tried; e.g. minera argenti vitrea, or silver glass, which consists only of silver and sulphur. When this ore is exposed to the flame, it melts instantly, and the sulphur flies off in fumes, leaving the silver pure upon the charcoal in a globular form. If this silver should be of a dirty appearance, which often is the case, it must be melted anew with a very little borax; and after it has been kept in fusion for a minute or two, so as to be perfectly melted and red-hot, suffered to cool, it may then be taken off the coal, and, being laid upon the steel plate, the silver is separated from the slag by one or two strokes of the hammer. The brass ring ought first to be placed upon the plate, to hinder the proof from flying off by the violence of the stroke, which otherwise would happen. The silver is then found enclosed in the slag of a globular form, and quite shining, as if it was polished. When a large quantity of silver is contained in a lead ore, viz. in a potter's ore, it can likewise be discovered by the blow-pipe.

Tin may be melted out of the pure tin ores in its metallic state. Some of these ores melt very easily, and yield their metal, if only exposed to the fire by themselves: but others are more refractory; and, as these melt very slowly, the tin, which sweats out in form of very small globules, is instantly burnt to ashes before these globules have time to unite and compose a larger globe, which might be seen by the eye, and not so soon destroyed by the fire; it is therefore necessary to add a little borax to these from the beginning, and then to blow the flame violently at the proof. The borax preserves the metal from being too soon calcined, and even contributes to the readier collecting of the small metallic particles, which soon form a globule of metallic tin at the bottom of the whole mass, nearest to the charcoal. As soon as so much of the metallic tin is produced as is sufficient to convince the operator of its presence, the fire ought to be discontinued, though the whole ore be not yet melted; because the whole of this kind of ore can seldom or never be reduced into metal by these experiments, a great proportion being always calcined: and, if the fire is continued too long, even the metal already reduced may be burnt; for tin is very soon deprived of its metallic state by fire.

Most of the lead ores may be reduced to a metallic state upon the charcoal. The mineræ plumbi calciformes, which are pure, are easily melted into lead; but such of them as are mixed with an ochra ferri, or any kind of earth, as clay, lime, &c., yield very little lead, and even none at all, if the heterogenea are combined in any large quantity. These therefore are not to be tried but in larger laboratories. However, every mineral suspected to contain any metallic substance may be tried by the blow-pipe, so as to give sufficient proofs whether it contain any or not, by its effects being different from those of the stones or earths, &c.

The mineræ plumbi mineralisitæ leave the lead in a metallic form, unless too large a quantity of iron is mixed with it. When a tessellated or steel-grained lead ore is exposed to the flame, its sulphur, and even the arsenic, if there be any, begins to fume, and the ore itself to melt into a globular form; the rest of the sulphur continues

then to fly off, if the flame be blown slowly upon the mass; but, on the contrary, very little of the sulphur will go off, if the flame be forced violently on it: in this case, the lead crackles and dissipates, throwing about every minute metallic particles. The sulphur being driven out as much as possible, which is known by finding no sulphureous vapor in smelling at the proof; the whole is suffered to cool, and then a globule of metallic lead will be left upon the coal. If any iron is contained in the ore, the lead, which is melted out of it, is not of a metallic shining, but rather of a black and uneven surface: a little borax must in this case be melted with it; and, as soon as no bubble is seen to rise any longer from the metal into the borax, the fire must be discontinued: when the mass is grown cold, the iron will be found scorified with the borax, and the lead left pure and of a shining color. Borax does not scorify the lead in these small experiments when it is pure; if the flame is forced with violence on it, a bubbling will ensue, resembling that which is observed when borax dissolves a body melted with it; but, when the fire ceases, the slag will be perfectly clear and transparent, and a quantity of very minute particles of lead will be seen spread about the borax, which have been torn off from the mass during the bubbling.

If such a lead ore is rich in silver, this last metal may likewise be discovered by this experiment; because, as the lead is volatile, it may be forced off, and the silver remain. To effect this, the lead, which is melted out of the ore, must be kept in constant fusion with a slow heat, that it may be consumed. This end will be sooner obtained, and the lead part quicker, if during the fusion the wind through the blow-pipe be directed immediately, but not forcibly, upon the melted mass, until it begin to cool; when the fire must be directed on it again. The lead, already in a volatilising state, will thus be driven out in form of a subtile smoke; and by thus continuing by turns to melt the mass, and blow off the lead, until no smoke is perceived, the silver will at last be obtained pure. As only very little bits of ores can be employed in these experiments, it will be difficult to extract the silver out of a poor ore, for some part of it will fly off with the lead, and what might be left is too small to be discerned by the eye. The silver thus obtained is easily distinguished from lead by the following marks: it must be red-hot before it can be melted, it cools sooner than lead; it is brighter and whiter than lead; and harder under the hammer.

The mineræ cupri calciformes, at least some of them, when not mixed with too much stone or earth, are easily reduced to copper with any flux; if the copper has not its natural bright color, it must be melted with a little borax, which purifies it. Some of these ores do not discover their metal, if not immediately melted with borax; the heterogenea contained in them hindering the fusion before these are scorified by the flux.

The gray copper ores, which only consist of copper and sulphur, are tried almost in the same manner. Being exposed to the flame by themselves, they instantly melt, and part of their sulphur goes off. The copper may afterwards be obtained in two ways: the one, by keeping the proof in fusion for about a minute, and afterwards suffering it to cool; when it will be found to have a dark and uneven appearance externally, but which, after being broken, discovers the metallic copper of a globular form in its centre, surrounded with a regulus, which still contains some sulphur and a portion of the metal; the other by being melted with borax, which last way sometimes makes the metal appear sooner.

The mineræ cupri pyritaceæ, containing copper, sulphur, and iron, may be tried with the blow-pipe if they are not too poor. In these experiments the ore ought to be calcined, and after that the iron scorified. For this purpose a bit of the ore must be exposed to a slow flame, that as much of the sulphur as possible may part from it before it is melted, because the ore commonly melts very soon, and then the sulphur is more difficultly driven off. After being melted, it must be kept in fusion with a strong fire for about a minute, that a great part of the iron may be calcined; and, after that, some borax must be added, which scorifies the iron, and turns with it to a black slag. If the ore is very rich, metallic copper will be had in the slag after the scorification. If the ore be of a moderate richness, the copper will still retain a little sulphur, and sometimes iron: the product will therefore be brittle, and must with great caution be separated from the slag, that it may not break into pieces; and, if this product is afterwards treated in the manner above described of the gray copper ores, the metal will soon be produced. But, if the ore is poor, the product, after the first scorification, must be brought into fusion, and afterwards melted with some fresh borax, to calcine and scorify the remaining portion of iron; after which it may be treated as mentioned in the last paragraph. The copper will in this case be found in a very small globule.

The copper is not easily scorified with this apparatus, when it is melted with borax, unless it has first been exposed to the fire by itself to be calcined. When only a little of this metal is dissolved, it instantly tinges the slag of a reddish-brown color, and mostly opaque; but as soon as this slag is kept in fusion for a little, it becomes quite green and transparent: and thus the presence of the copper may be discovered by the color, when it is concealed in heterogeneous bodies, so as not to be discovered by any other experiment. If metallic copper is melted with borax by a slow fire, and only for a very little time, the slag becomes of a fine transparent blue or violet color, inclining more or less to green: but this color is not entirely owing to the copper, because the same color is to be had in the same manner from iron; and those glasses which are colored with either of these metals soon lose their color if exposed to a strong fire, and become quite clear. Besides, if this glass, tinged blue with the copper, is again melted with more of this metal, it becomes of a good green color, which remains long unchanged in the fire.

The iron ores, when pure, can never be melted, per se by the blow-pipe alone; nor do they yield their metal when melted with fluxes: because they require too strong a heat to be brough

into fusion; and both the ore and the metal are very soon calcined. This easy calcination is also the reason why the fluxes readily scorify this ore, and even the metal itself. The iron is more easily scorified than the copper. The iron is, however, discovered without much difficulty, although it were mixed but in a very small quantity with neterogeneous bodies. The ores are all attracted by the loadstone, some without any previous calcination, and others without being roasted. When a clay is mixed with a little iron, it commonly melts by itself in the fire; but, if iron is contained in a limestone, it does not promote the fusion, but gives the stone a dark and sometimes a deep black color, which is always the character of iron. A minera ferri calciformis pura crystallisata is commonly of a red color: This, being exposed to the flame, becomes quite black; and is then readily attracted by the loadstone, which it was not before. Besides these signs, iron is discovered by tinging the slag of a green transparent color, inclining to brown, when only a little of the metal is scorified; but, as soon as any large quantity thereof is dissolved in the slag, this becomes first a blackish-brown, and afterwards quite black and opaque.

Bismuth is known by its communicating a yellowish brown color to borax; and arsenic by its volatility and garlick smell.

Antimony, both in form of regulus and ore, is wholly volatile in the fire when it is not mixed with any other metal except arsenic; and is known by its particular smell, easier to be distinguished than described. When the ore of antimony is melted upon the charcoal, it bubbles constantly during its volatilising.

Zinc ores are not easily tried upon charcoal but the regulus of zinc exposed to the fire upon it burns with a beautiful blue flame, and forms itself almost instantly into white flowers, called flowers of zinc.

Cobalt is remarkable for giving to the glass a blue color, which is the zaffre or smalt. To produce this, a piece of cobalt ore must be calcined in the fire, and afterwards melted with borax. As soon as the glass, during the fusion, from being clear, grows opaque, it is a sign that it is tinged a little; the fire is then to be discontinued, and the operator must take hold, with the nippers, of a little of the glass, whilst yet hot, and draw it out slowly in the beginning, but afterwards very quickly, before it cools, whereby a thread of the colored glass is procured, more or less thick, wherein the color may easier be seen than in a globular form. This thread melts easily, if only put in the flame of the candle without the help of the blow-pipe. If this glass be melted again with more of the cobalt, and kept in fusion for a while, the color becomes very deep; and thus the color may be varied at pleasure. When the cobalt ore is pure, or contains but little iron, a cobalt regulus is almost instantly produced in the borax during the fusion; but, when it is mixed with a quantity of iron, this last metal ought first to be separated, which is easily performed, as it scorifies sooner than the cobalt; therefore, as long as the slag retains any brown or black color, it must be separated, and melted again with fresh borax, until it shows the blue color.

Nickel is very seldom to be had; and as its ores are seldom free from mixtures of other metals, it is very difficultly tried with the blow-pipe. However, when mixed with iron and cobalt, it is easily freed from these heterogeneous metals, and reduced to a pure nickel regulus by scorification with borax, because both the iron and cobalt sooner scorify than the nickel. The regulus or nickel itself is of a green color when calcined: it requires a pretty strong fire before it melts, and tinges the borax with a hyacinth color. Manganese gives the same color to borax; but its other qualities are quite different, so as not to be confounded with the nickel.

When those ores are to be reduced whose metals are very easily calcined, as tin, zinc, &c., it may be of service to add hard resin, as the charcoal cannot afford enough of it in the open fire of these assays. The manner of melting the volatile metals out of their ores per descensum might also be imitated: for instance, a hole might be made in the charcoal, wide above and very narrow at the bottom; a little piece of the ore being then laid at the upper end of the hole, and covered with some very small pieces of the charcoal, the flame must be directed on the top; the metal might thus run into the hole below, concealed from the violence of the fire, particularly if the ore is very fusible.

The use of the apparatus above referred to, and which may be called a pocket laboratory, as the whole admits of being packed into a small case, is chiefly calculated for a travelling mineralist. But a person who always resides at one place may make it more commodious to himself, and avoid the trouble of blowing with the mouth. For this purpose he may have the blowpipe go through a hole in a table, and fixed underneath to a small pair of bellows with double bottoms, such as some of the glass-blowers use, and then nothing more is required than to move the bellows with the feet during the experiment; in this case a lamp may be used instead of a candle. It would only be necessary to observe that, in proportion as the nozzle of the pipe is enlarged, the quantity of the flame must be augmented by a thicker wick in the lamp, and the force of blowing increased by weights laid on the bellows; a much intenser heat would thus be produced by a pipe of considerable opening at the end, by which the experiments must undoubtedly be carried farther than by the common blowpipe.

A traveller, who has seldom an opportunity of carrying many things along with him, will find this laboratory and its apparatus sufficient for most experiments that can be made on a journey. He should also have a little box including the different acids, and one or two matrasses to try mineral bodies in liquid menstrua. These are, the acids of nitre, of vitriol, and of common salt. Most of the stones and earths are attacked, at least in some degree, by the acids; but the calcareous are the easiest of all to be dissolved by them. The acid of nitre is that which is most used in these experiments; it dissolves the limestone, when pure, perfectly, with a violent effervescence, and the solution becomes clear: when the limestone enters into some other body, it is

nevertheless discovered by this acid, through a greater or less effervescence in proportion to the quantity of the calcareous particles, unless there are so few as to be almost concealed from the acid by the heterogeneous ones. A calcareous body, which nearly resembles a siliceous or argillaceous one, may be thus known from these latter, without the blow-pipe, merely by pouring one or two drops of this acid upon it; which is very convenient, when there is neither opportunity nor time to use this instrument.

The gypsa, which consist of lime and the vitriolic acid, are not in the least attacked by the acid of nitre, if they contain a sufficient quantity of their own acid; because the vitriolic acid has a stronger attraction to the lime than the acid of nitre; but, if the calcareous substance is not perfectly saturated with the acid of vitriol, then an effervescence arises with the acid of nitre, more or less in proportion to the want of the vitriolic acid. These circumstances are often very essential in distinguishing the calcarea and gypsa.

The acid of nitre is likewise necessary in trying the zeolites, of which some species have the singular effect to dissolve with effervescence in this acid; and within a quarter of an hour, though sometimes not until several hours after, to change the whole solution into a clear jelly, of so firm a consistence that the glass wherein it is contained may be inverted without its falling out. If any mineral body is tried in this menstruum, and only a small quantity is suspected to be dissolved, though it was impossible to distinguish it with the eye during the solution, it can be easily discovered by adding to it ad saturitatem a clear solution of the alkali, when the dissolved part will be precipitated, and fall to the bottom. For this purpose the soda is very useful. The acid of nitre will suffice for making experiments upon stones and earths; but, if the experiments are to be extended to the metals, the other two acids are also necessary.

Another instrument is also necessary to a complete Pocket Laboratory, viz. a washing trough in which the mineral bodies, and particularly the ores, may be separated from each other, and from the adherent rock, by water. This trough is very common in laboratories, and is used of different sizes; but here only one is required of a moderate size, such as twelve inches and a half long, three inches broad at one end, and one inch and a half at the other end, sloping down from the sides and the broad end to the bottom, where it is three-quarters of an inch deep. It may, however, be made of much smaller dimensions. It is commonly made of wood, which ought to be chosen smooth, hard, and compact, wherein are no pores in which the minute grains of the pounded matter may lie concealed. If any such matter is to be washed as is suspected to contain some native metal, such as silver or gold, a trough should be procured for this purpose of a very shallow slope, because the minute particles of the native metal have then more power to assemble together at the broad end, and separate from the other matter.

The management of this trough, or the manner of washing, is this:—When the matter is mixed with about three or four times its quantity of water in the trough, this is kept very loose between two fingers of the left hand, and some light strokes given on its broad end with the right, that it may move backwards and forwards; by which means the heaviest particles assemble at the broad and lower end, from which the lighter ones are to be separated by inclining the trough, and pouring a little water on them. By repeating this process all such particles as are of the same gravity may be collected together, and separated from those of different gravity, provided they were before equally pounded: though such as are of a clayey nature are often very difficult to separate from the rest, which, however, is of no great consequence to a skilful and experienced washer. The washing process is very necessary, as there are often rich ores, and even native metals, found concealed in earths and sand in such minute particles as not to be discovered by any other means.

For performing experiments in the humid way the chief articles (and which must be kept in a separate case) are, a collection of phials, containing the principal acids, tests, precipitants, and re-agents, both for examining mineral bodies by the humid way, and for analysing the various kinds of mineral waters. Those with acids and corrosive solutions have not only ground stopples, but also an external cap to each, bound over the stopple, and secured downward by a bit of wax between both to confine the corrosive and volatile fluids. But those which contain mild fluid liquors do not need such external caps: and those with dry inoffensive substances are only stopped with corks. There are also two smaller cylindrical phials to exhibit the changes of color produced by some of the re-agents in those analytical assays. There are also two or three small mattrasses to hold the substances with their solvents over the fire; a small glass funnel for pouring the fluids; a small porcelain mortar, with its pestle; one or two crucibles of the same substance; a small wooden trough to wash the ground ores; some glass sticks to stir up the fluid mixtures; and, finally, pieces of paper tinged red, yellow, and blue, by the tinctures of Fernambuc wood (commonly called Brasil wood), turmeric, and litmus, thickened with a little starch.

The lamp furnace laboratory, for experiments both by the humid and the dry way, is a very curious and useful; though small apparatus. It is an improvement of one contrived by M. Morveau, in consequence of the information he received from his friend the president de Virly, who saw at Upsal how advantageously the late eminent Sir T. Bergman availed himself of this convenience for many analytical processes in miniature, by the use of very small glass vessels about an inch diameter, and other implements of proportional size, for performing various chemical operations.

When these processes are properly conducted, though in miniature, the lamp furnace will prove amply sufficient to perform, in a few minutes, and with very little expense, the various solutions, digestions, and distillations, which otherwise would require large vessels, stills, retorts, reverberatory furnaces, &c., to ascertain the con-

ponent parts of natural bodies; though it is not always sufficient to ascertain their respective quantities. In this last case operations must be performed in great laboratories, and on a large scale, at a considerable expense. But the substances are sometimes too valuable; for instance, when precious stones are to be examined, the last way never can be attempted.

These small processes have likewise another advantage which cannot be obtained in large works, viz. that one can observe the gradual progress of each operation; retard or urge it, as it may require; and ascertain at pleasure each step of every experiment, with the phenomena attending it. See CHEMISTRY.

Before a mineral is submitted to analysis it ought to be reduced to an impalpable powder. This is by no means an easy task when the stone is extremely hard. It ought to be raised to a bright red or white heat in a crucible, and then instantly thrown into cold water. This sudden transition makes it crack and break into pieces. If these pieces are not small enough the operation must be repeated on each, till they are reduced to the proper size. These fragments are then to be beaten to small pieces in a polished steel mortar; the cavity of which should be cylindrical, and the steel pestle should fit it exactly to prevent any of the stone from escaping during the act of pounding. As soon as the stone is reduced to pretty small pieces it ought to be put into a mortar of rock crystal, or flint, and reduced to a coarse powder. This mortar should be about four inches in diameter, and rather more than an inch in depth. The pestle should be formed of the same stone with the mortar.

When the stone has been reduced to a coarse powder, a certain quantity, weighing exactly 100 grains for instance, ought to be reduced to as fine a powder as possible. This is best done by pounding small quantities of it at once, not exceeding ten grains. The powder is as fine as possible when it feels soft, adheres together, and as it were forms a cake under the paste. It ought then to be weighed exactly. It will almost always be found heavier after being pounded than it was before, owing to a certain quantity of the substance of the mortar being rubbed off during the grinding, and mixed with it. This additional weight must be carefully noted; and, after the analysis, a portion corresponding to it must be subtracted.

It is necessary to have a crucible of pure silver, or, what is far preferable, of platinum, capable of holding rather more than seven cubic inches of water, with a cover of the same metal; and a spatula of the same about four inches long. The dishes in which the solutions, evaporations, &c., are performed ought to be of glass or porcelain. Those of porcelain are cheaper because they are not so apt to break. Those which Vauquelin uses are of porcelain; they are sections of spheres, and are glazed both within and without, except that part of the bottom which is immediately exposed to the fire.

Let 100 or 200 grains of the stone to be analysed, previously reduced to a fine powder, be mixed with three times its weight of pure potass and a little water, and exposed in the silver or platinum crucible to a strong heat. The heat should at first be applied slowly, and the matter should be constantly stirred to prevent the potass from swelling and throwing any part out of the crucible. When the whole water is evaporated the mixture should be kept for half an hour or three-quarters in a strong red heat.

If the matter in the crucible melts completely, and appears as liquid as water, we may be certain that the stone consists chiefly of silica; if it remains opaque, and of the consistence of paste, the other earths are most abundant; if it remains in the form of a powder alumina is the prevalent earth. If the matter be of a dark or brownish-red color it contains oxide of iron; if it is grass green, manganese is present; if yellowish green, chromum. When the crucible has been taken from the fire, and wiped on the outside, it is to be placed in a capsule of porcelain, and filled with water. This water is to be renewed from time to time, till all the matter is detached from the crucible. The water dissolves a part of the combination of the alkali with the silica and alumina of the stone; and, if a sufficient quantity were used, it would dissolve the whole of that combination.

Muriatic acid is now to be poured in till the whole of the matter is dissolved. At first a flaky precipitate appears, because the acid combines with the alkali which kept it in solution. Then an effervescence takes place, owing to the decomposition of some carbonate of potass, formed during the fusion. At the same time the flaky precipitate is redissolved; as is also that part of the matter which, not having been dissolved in the water had remained at the bottom of the dish in the form of a powder. This powder, if it consists only of silica and alumina, dissolves without effervescence; but, if it contains lime, an effervescence takes place. If this solution be colorless, we may conclude that it contains no metallic oxide, or only a very small portion; if the color be purplish red, it contains manganese; orange red indicates the presence of iron; and golden yellow that of chromum.

This solution is to be poured into a capsule of porcelain, covered with paper, and evaporated to dryness in a sand bath. When the evaporation is drawing to its completion, the liquor assumes the form of jelly. It must then be stirred constantly with a glass or porcelain rod, to facilitate the disengagement of the acid and water, and to prevent one part of the matter from being too much and the other not sufficiently dried. Without this precaution the silica and alumina would not be completely separated from each other.

When the matter is reduced almost to a dry powder, a large quantity of pure water is to be poured on it; and, after exposure to a slight heat, the whole is to be poured on a filter. The powder which remains on the filter is to be washed repeatedly, till the water with which it has been washed ceases to precipitate silver from its solutions. This powder is the whole of the silica which the stone we are analysing contained. It must first be dried between folds of blotting paper; then heated red hot in a platinum c

weighed while yet warm. It ·vder, of a white color, not and entirely soluble in ·is contaminated with ws that the evapo- ned at too high oxide the silica nd then washed d solution must be passed through the denominate A.

is to be evaporated till xceed thirty cubic inches, n pint. A solution of car- s then to be poured into it, till precipitates. It ought to be minutes to enable all the precipitate bottom. When the whole of the pre- as collected at the bottom, the superna- uid is to be decanted off; and, water being tuted in its place, the precipitate and water to be thrown upon a filter. When the water has run off, the filter, with the precipitate upon it, is to be placed between folds of blotting paper. When the precipitate has acquired some consistence, it is to be carefully collected by an ivory knife, mixed with a solution of pure potass, and boiled in a porcelain capsule. If any alumina or glucina be present, they will be dissolved in the potass; while the other substances remain untouched in the form of a powder, which we shall call B.

Into the solution of potass as much acid must be poured as will not only saturate the potass, but completely redissolve any precipitate which may have at first appeared. Carbonate of ammonia is now to be added in such quantity that the liquid shall taste of it. By this addition the whole of the alumina will be precipitated in white flakes, and the glucina will remain dissolved, provided the quantity of carbonate of ammonia used be not too small. The liquid is now to be filtered; and the alumina, which will remain on the filter, is to be washed, dried, heated red hot, and then weighed. To see if it be really alumina, dissolve it in sulphuric acid, and add a sufficient quantity of sulphate or acetate of potass; if it be alumina, the whole of it will be converted into crystals of alum.

Let the liquid, which has passed through the filter, be boiled for some time; and the glucina, if it contains any, will be precipitated in a light powder, which may be dried and weighed. When pure, it is a fine, soft, very light, tasteless powder, which does not concrete when heated, as alumina does.

The residuum B may contain lime, magnesia, and one or more metallic oxides. Let it be dissolved in weak sulphuric acid, and the solution evaporated to dryness. Pour a small quantity of water on it. The water will dissolve the sulphate of magnesia and the metallic sulphate; but the sulphate of lime will remain undissolved. Let it be heated red-hot in a crucible and weighed. The lime amounts to 0·42 of the weight. Let the solution, containing the remaining sulphates, be diluted with a large quantity of water; let a small excess of acid be added; and then let a saturated carbonate of potass be poured in. The oxides of chromum, iron, and nickel, will be precipitated, and the magnesia and oxide of manganese will remain dissolved. The precipitate we shall call C.

Into the solution let a solution of hydrosulphuret of potass be poured, and the manganese will be precipitated in the state of a hydrosulphuret. Let it be calcined in contact with air, and weighed. The manganese may then be precipitated by pure potass, washed, exposed to a red heat, and then weighed.

Let the residuum C be boiled repeatedly with nitric acid, then mixed with pure potass; after being heated let the liquid be decanted off. Let the precipitate, which consists of the oxides of iron and nickel, be washed with pure water; and let this water be added to the solution of the nitric acid and potass. That solution contains the chromum converted into an acid. Add to this solution an excess of muriatic acid, and evaporate till the liquid assumes a green color; then add a pure alkali. The chromum precipitates in the state of an oxide, and may be dried and weighed.

Let the precipitate, consisting of the oxides of iron and nickel, be dissolved in muriatic acid; add an excess of ammonia: the oxide of iron precipitates. Let it be washed, dried, and weighed. Evaporate the solution, and the oxide of nickel will also precipitate. Its weight may be ascertained in the same manner with the other ingredients.

The weights of all the ingredients are now to be added together, and their sum total compared with the weight of the matter analysed. If the two are equal, or if they differ only by 0·03 or 0·04 parts, we may conclude that the analysis has been properly performed; but, if the loss of weight be considerable, something or other has been lost. The analysis must therefore be repeated with all possible care. If there be still the same loss of weight, we may conclude that the stone contains some substance, which has either evaporated by heat, or is soluble in water.

A fresh portion of the stone must therefore be broken into small pieces, and exposed in a porcelain crucible to a strong heat. If it contain water, or any other volatile substance, they wil. come over into the receiver; and their nature and weight may be ascertained. If nothing comes over, or if what comes over is not equal to the weight wanting, we may conclude, that the stone contains some ingredient which is soluble in water.

To discover whether it contains potass, let the stone, reduced to an impalpable powder, be boiled five or six times in succession, with very strong sulphuric acid, applying a pretty strong heat towards the end of the operation, to expel the excess of acid; but taking care that it be not strong enough to decompose the salts which have been formed.

Water is now to be poured on, and the residuum, which does not dissolve, is to be washed with water till it becomes tasteless. The watery solution is to be filtered, and evaporated to dryness, in order to drive off any excess of acid which may be present. The salts are to be again

dissolved in water; and the solution, after being boiled for a few moments, is to be filtered and evaporated to a consistence proper for crystallising. If the stone contains a sufficient quantity of alumina, and if potass be present, crystals of alum will be formed; and the quantity of potass may be discovered by weighing them, it being nearly one-tenth of their weight. If the stone does not contain alumina, or not in sufficient quantity, a solution of pure alumina in sulphuric acid must be added. Sometimes the alum, even when potass is present, does not appear for several days or even weeks; and sometimes, when a great quantity of alumina is present, if the solution has been too much concentrated by evaporation, the sulphate of alumina prevents the alum from crystallising at all. Care, therefore, must be taken to prevent this last source of error. The alum obtained may be dissolved in water, and barytic water poured into it as long as any precipitate forms. The liquor is to be filtered and evaporated to dryness. The residuum will consist of potass, and a little carbonate of potass. The potassa may be dissolved in a little water. This solution, evaporated to dryness, gives us the potassa pure; which may be examined and weighed.

If no crystals of alum can be obtained, we must look for some other substance than potassa. The stone may contain soda. The presence of this alkali may be discovered by decomposing the solution in sulphuric acid, already described, by means of ammonia. The liquid which remains is to be evaporated to dryness, and the residuum is to be calcined in a crucible: the sulphate of ammonia will thus be volatilised, and the soda will remain. It may be redissolved in water, crystallised, and examined.

If sulphuric acid does not attack the stone, as is often the case, it must be decomposed by fusion with soda, in the manner formerly directed with potassa. The matter, after fusion, is to be diluted with water, and then saturated with sulphuric acid. The solution is to be evaporated to dryness, the residuum again dissolved in water, and evaporated. Sulphate of soda will crystallise first; and by a second evaporation, if the stone contains potassa and alumina, crystals of alum will be deposited. The presence of potassa may be discovered by mixing with a somewhat concentrated solution of muriate of platinum the salt obtained, either by decomposing the stone immediately by an acid, or by saturating with an acid the matter obtained by fusing the stone with soda. If any potassa be present, a very red precipitate will be formed. This precipitate is a triple salt, composed of potassa, muriatic acid, and oxide of platinum. Ammonia, indeed, produces the same precipitate, but has not hitherto been discovered in stones.

In this manner may simple stones and aggregates be analysed. As to saline stones, their analysis must vary according to the acid which they contain. But almost all of them may be decomposed by one or other of two methods: viz.

I. *Analysis of carbonate of strontian.*—Klaproth analysed this mineral, by dissolving 100 parts of it in diluted muriatic acid: during the solution thirty parts of carbonic acid escaped. The solution crystallised in needles, and, when dissolved in alcohol, burnt with a purple flame. Therefore it contained strontian. He dissolved a grain of sulphate of potassa in six ounces of water, and let fall into it three drops of the muriatic solution. No precipitate appeared till next day. Therefore the solution contained no barytes; for, if it had, a precipitate would have appeared immediately. He then decomposed the muriatic acid solution, by mixing it with carbonate of potassa. Carbonate of strontian precipitated. By the application of a strong heat the carbonic acid was driven off. The whole of the earth which remained was dissolved in water. It crystallised; and, when dried, weighed sixty-nine and a half.

II. *Analyses of sulphate of strontian.*—Vauquelin analysed an impure specimen of this mineral as follows:—on 200 parts of the mineral, diluted nitric acid was poured. A violent effervescence took place, and part of the mineral was dissolved. The undissolved portion, after being heated red hot, weighed 167. Therefore thirty-three parts were dissolved. The nitric solution was evaporated to dryness: a reddish substance remained, which indicated the presence of oxide of iron. This substance was redissolved in water, and some ammonia mixed with it; a reddish precipitate appeared, which, when dried, weighed one, and was oxide of iron. The remainder of the solution was precipitated by carbonate of potassa. The precipitate weighed, when dried, twenty, and possessed the properties of carbonate of lime. Therefore 200 parts of this mineral contain twenty of carbonate of lime, one of oxide of iron, and the remainder of the thirty-three parts he concluded to be water.

The 167 parts, which were insoluble in nitric acid, were mixed with 500 parts of carbonate of potass, and 700 parts of water, and boiled for a considerable time. The solution was then filtered, and the residuum washed and dried. The liquid scarcely effervesced with acids; but with barytes it produced a copious precipitate, totally indissoluble in muriatic acid. Therefore it contained sulphuric acid. The undissolved residuum, when dried, weighed 129 parts. It dissolved completely in muriatic acid. The solution crystallised in needles: when dissolved in alcohol it burnt with a purple flame, and, in short, had all the properties of muriate of strontian. Therefore these 129 parts were carbonate of strontian. Now 100 parts of this carbonate contain 30 of carbonic acid, therefore 129 contain 38·7. Therefore the mineral must contain, in 200 parts, 90·3 of strontian. Now the insoluble residuum of 167 was pure sulphate of strontian; and we have seen that it contained 90·3 of strontian. Therefore the sulphuric acid must amount to 76·7 parts.

Nearly in the same manner as in the first of these examples, may the analysis of carbonate of lime and barytes be performed; and nearly in the same manner with the second may we analyse the sulphates of lime and barytes.

Phosphate of lime may be dissolved in muriatic acid, and the lime precipitated by sulphuric

acid, and its quantity ascertained by decomposing the sulphate of lime contained. The liquid solution may be evaporated to the consistence of honey, mixed with charcoal powder, and distilled in a strong heat. By these means phosphorus will be obtained. The impurities with which phosphate may be contaminated, will partly remain undissolved, and partly be dissolved in muriatic acid. They may be detected and ascertained by the rules laid down in the beginning of this chapter.

The fluate of lime may be mixed with sulphuric acid and distilled. The fluoric acid will come over in the form of gas, and its weight may be ascertained. What remains in the retort, which will consist chiefly of sulphate of lime, may be analysed by the rules already laid down.

The borate of lime may be dissolved in nitric or sulphuric acid: the solution may be evaporated to dryness, and the boracic acid separated from the residuum by alcohol, which will dissolve it without acting on any of the other ingredients. The remainder of the dry mass may be analysed by the rules laid down in this chapter.

The diamond is a precious stone which has been known from the remotest ages. Its figure varies considerably, but most commonly it is crystallised in the form of a six-sided pyramid. It is the hardest of all bodies; the best tempered steel makes no impression on it; diamond powder can only be obtained by grinding one diamond against another. Its specific gravity is about 3·5. It is a non-conductor of electricity.

As the diamond is not affected by a considerable heat, it was for many ages considered as incombustible. Sir Isaac Newton observing that combustibles refract light more powerfully than other bodies, and that the diamond possesses this property in great perfection, suspected it, from that circumstance, to be capable of combustion. This singular conjecture was verified in 1694 by the Florentine academicians, in presence of Cosmo III., grand duke of Tuscany. By means of a burning-glass, they consumed several diamonds.

No attempt, however, was made to ascertain the product till 1772. Lavoisier, in a memoir published that year, showed that when the diamond is burnt carbonic acid is obtained, and that there is a striking analogy between it and charcoal. In 1785 Guyton Morveau found that the diamond is combustible when dropped into melted nitre; that it burns without leaving any residuum, and in a manner analogous to charcoal. This experiment was repeated with more precision by Mr. Tennant in 1797. The conclusion he drew from it was, that, when a diamond is burnt, the whole of the product is carbonic acid gas; that a given weight of diamond yields just as much carbonic acid gas as the same weight of charcoal; and that diamond and charcoal are both composed of the very same substance.

This conclusion, that diamond is nothing else but charcoal, was directly contrary to what one would have expected from comparing the two substances together. Their color, hardness, specific gravity, and electrical properties are exceedingly different; nor do they resemble each other in their combustibility. Charcoal takes fire at 370°, gives out a great deal of heat, and, when once kindled in oxygen gas, continues to burn till it be wholly consumed. The diamond, before it can be burnt, must be exposed to the sun's rays in the focus of a large burning-glass, or to a heat not under 5000°: even then it consumes but slowly, and ceases to burn the instant the action of the burning-glass is withdrawn. Its surface assumes a black color like charcoal; this crust is soon wasted, and another is formed in its place. In this manner a diamond, weighing 3·089 gr. Troy, gradually wasted away completely, when exposed by Morveau for one hour and forty minutes in the focus of the celebrated burning-glass of Tschirnhausen, while a thermometer exposed to the sun stood at 104°.

Coal is composed of charcoal, bitumen, and some portion of earth. The earths may be detected by burning completely a portion of the coal to be analysed. The ashes which remain after incineration consist of the earthy part. Their nature may be ascertained by the rules laid down in the preceding chapter. For the method of ascertaining the proportion of charcoal and bitumen in coal, we are indebted to Dr. Kirwan.

When nitre is heated red hot, and charcoal is thrown on it, a violent detonation takes place; and, if the quantity of charcoal be sufficient, the nitre is completely decomposed. Now it requires a certain quantity of pure charcoal to decompose a given weight of nitre. From the experiments of Lavoisier it follows, that, when the detonation is performed in close vessels under water, 13·21 parts of charcoal are capable of decomposing 100 parts of nitre. But, when the detonation is performed in an open crucible, a smaller proportion of charcoal is necessary, because part of the nitre is decomposed by the action of the surrounding air. Scheele found that, under these circumstances, ten parts of plumbago were sufficient to decompose ninety-six parts of nitre; and Dr. Kirwan found that nearly the same quantity of charcoal was sufficient for producing the same effect.

Macquer long ago observed that no volatile oily matter will detonate with nitre, unless it be previously reduced to a charcoal; and that then its effect upon charcoal is precisely proportional to the charcoal which it contains. Dr Kirwan, upon trying the experiment with vegetable pitch and maltha, found that these substances did not detonate with nitre, but merely burn upon its surface with a white or yellow flame; and that, after they were consumed, nearly the same quantity of charcoal was necessary to decompose the nitre which would have been required if no bitumen had been used at all. Now coals are chiefly composed of charcoal and bitumen. It occurred therefore to Dr. Kirwan that the quantity of charcoal which any coal contains may be ascertained by detonating it with nitre: for, since the bitumen of the coal has no effect in decomposing nitre, it is evident that the detonation and decomposition must be owing to the charcoal of the coal; and that, therefore, the quantity of coal necessary to decompose a given portion of nitre, will indicate the quantity of

carbon which it contains: and the proportion of charcoal and earth which any coal contains, being ascertained, its bituminous part may be easily had from calculation.

The crucible which he used in his experiments was large; it was placed in a wind furnace, at a distance from the flue, and the heat in every experiment was as equal as possible. The moment the nitre was red hot, the coal, previously reduced to small pieces of the size of a pin's head, was projected in portions of one or two grains at a time, till the nitre would no longer detonate; and every experiment was repeated several times to ensure accuracy. He found that 480 grains of nitre required fifty grains of Kilkenny coal to decompose it by this method. Therefore ten grains would have decomposed ninety-six of nitre; precisely the quantity of charcoal which would have produced the same effect. Therefore Kilkenny coal is composed almost entirely of charcoal.

Cannel coal, when incinerated, left a residuum of 3·12 in the 100 parts of earthy ashes: 66·5 grains of it were required to decompose 480 grains of nitre; but fifty parts of charcoal would have been sufficient: therefore 66·5 grains of cannel coal contained fifty grains of charcoal and 2·08 of earth; the remaining 14·42 grains must be bitumen. In this manner may the composition of any other coal be ascertained.

As for *sulphur*, to ascertain any accidental impurities with which it may be contaminated, it ought to be boiled in thirty times its weight of water, afterwards in diluted muriatic acid, and lastly treated with nitro-muriatic acid. These substances will deprive it of all its impurities, without acting on the sulphur itself, if the proper cautions be attended to. The sulphur may then be dried and weighed. The deficiency in weight will mark the quantity of the substances which contaminate the sulphur. The solutions may be evaporated and examined according to the rules laid down in the second and fourth chapters.

The diversity of *metallic ores* is so great that no general method of analysis can be given.

Gold ores. The presence of gold may easily be detected, by treating the mineral supposed to contain it with nitro-muriatic acid, and dropping muriate of tin into the solution. If the solution contains any gold, a purple precipitate immediately appears.

Native gold ought to be dissolved in nitro-muriatic acid; the silver, if any be present, falls to the bottom in the state of muriate, and may be separated by filtration and weighed. Pour sulphate of iron into the solution, and the gold is precipitated in the metallic state. The copper, if any be present, may be precipitated by a plate of iron. The presence of iron may be ascertained by dropping tincture of nut-galls into a portion of the solution.

The auriferous pyrites may be treated with diluted nitrous acid, which dissolves the iron, and separates the sulphur. The gold remains insoluble in the state of small grains.

Ores of platinum.—The most complete treatise on the analysis of this metal is that of Proust. But even his experiments are not sufficient to make us thoroughly acquainted with this complicated ore. Proust first separates the sand with which the grains of platina are mixed by exposing them to the blast of air. By heat he evaporates the mercury which still adheres to them, and then picks out the grains of gold, thus rendered visible. The ore is then dissolved in an acid composed of one part nitre and three parts muriatic acid. A black powder remains. This powder, when roasted, gives out phosphorus and sulphur. After this it is dissolved by nitro-muriatic acid, except a small residuum, which is plumbago. The solutions are then mixed. They consist of muriates of platinum and oxy-muriates of copper and iron. By evaporating till the liquid, when cold, assumes a consistency greater than honey, and inclining the retort, the oxy-muriates run off, and leave the muriate of platinum, which may be obtained pure by repeated solutions and crystallisations. The solution containing the muriates, and perhaps also a little platinum, is to be diluted with a great proportion of water, and pure ammonia dropt in. The red oxide of iron precipitates, and may be estimated by weighing it. When the solution is somewhat concentrated, ammonia precipitates the platinum in the state of a triple salt; and the copper, which now only remains, may be precipitated by a plate of iron.

Ores of silver.—The analysis of the ores of silver has been always considered as very important, on account of the great value of the metal.

1. Native silver is to be dissolved in nitric acid. The gold, if the ore contains any, remains in the state of a black powder, and may be dried and weighed. The silver may be precipitated by common salt: 100 parts of the precipitate, dried, denote about seventy-five parts of silver. The presence of copper may be ascertained by the green color of the solution, and by the blue color it assumes on adding ammonia. The copper may be precipitated by a plate of iron, or by the rules laid down hereafter. When the ore contains arsenic, its proportion may be estimated by weighing before and after fusion; for the arsenic is dissipated by heat; or the ore may be dissolved in nitric acid, which acidifies the arsenic. After the separation of the silver, the arsenic acid may be precipitated by nitrate of lead; 100 parts of the dry precipitate indicating about twenty-two of the arsenic.

2. Alloy of silver and antimony is to be treated with nitric acid, which dissolves the silver, and oxidates the antimony. The silver is estimated as above. The oxide of antimony may be reduced by fusion with four times its weight of black flux and a little soap.

3. Sulphuret of silver is to be treated with diluted nitric acid, which dissolves the silver, leaving the greater part of the sulphur untouched. The residuum is to be dried, and then the sulphur burnt off. The loss of weight gives the sulphur. The residuum is the gauge of the ore, which may be analysed by the rules laid down in the last chapter. The silver is to be precipitated by common salt; and the other metals, if any be present, may be ascertained as above. Part of the sulphur is always acidified. The acid thus formed may be precipitated by nitrate of

barytes; 100 parts of the dried precipitate indicating about 14·5 of sulphur.

4. Antimoniated silver ore was analysed by Klaproth thus: 100 parts were boiled in diluted nitric acid. The residuum, washed and dried, was twenty-six. These twenty-six were digested in nitro-muriatic acid. The residuum now weighed thirteen (so that thirteen had been dissolved), twelve of which were sulphur, and burnt away, leaving one part of silica. The nitro-muriatic solution, when diluted largely with water, let fall a precipitate, which weighed thirteen (or ten of pure antimony), and had the properties of oxide of antimony; for they did not evaporate till heated to redness; but, at that temperature, were dissipated in a gray smoke. The nitric solution was green. Common salt occasioned a precipitate, which weighed 87·75, equivalent to 65·81 of pure silver. After the separation of this muriate of silver, sulphate of soda occasioned no precipitate. Therefore the solution contained no lead. When supersaturated with soda, a gray precipitate fell, weighing five parts. On burning coals this precipitate gave out an arsenical smell. It was redissolved in nitric acid; sulphureted alkali occasioned a smutty brown precipitate; and the prussic alkali a prussian blue, which, after torrefaction, was magnetic. Hence he concluded that these five parts were a combination of iron and arsenic acid. The nitric solution, which had been supersaturated with ammonia, was blue; he therefore suspected that it contained copper. To discover this, he saturated it with sulphuric acid, and put into it a polished plate of iron. The quantity of copper was so small that none could be collected on the iron.

5. Sulphuret of silver and copper may be analysed as No. 3, separating the copper by a plate of iron.

6. Calciform silver ore may be analysed as No. 2, separating the copper by an iron plate, and estimating the carbonic acid that escapes when the ore is heated or dissolved in nitric acid.

7. Red silver ore was analysed by Vauquelin thus: 100 parts were digested in 500 parts of nitric acid previously diluted with water. The undissolved residuum, being washed and dried, weighed 42·06. Being treated with muriatic acid, it was all dissolved except 14·66 parts, which were sulphur. The muriatic solution, when diluted with a great quantity of water, deposited a white powder, which weighed 21·25, and was oxide of antimony. The nitric acid solution remained to be examined. Muriatic acid occasioned a heavy precipitate, which weighed 72·66 parts, and which was muriate of silver. Re-agents showed that the acid retained no other substance in solution.

8. Muriate of silver was analysed by Klaproth as follows: 100 parts were mixed with thrice their weight of pure carbonate of potassa, and melted together in a glass retort. The mass was dissolved in water, and the solution filtered. A residuum remained, which was dissolved in nitric acid, with the exception of a red powder; which, treated with nitro-muriatic acid, was dissolved, except a little muriate of silver, which, when reduced, yielded 0·5 of pure silver. Ammonia precipitated from the nitro-muriatic solution 2·5 parts oxide of iron. The nitric solution was precipitated by common salt; the muriate of silver thus obtained, yielded, when reduced, 67·25 of pure silver. The original aqueous solution of the alkaline mass was saturated with acetous acid, on which it deposited 1·75 parts of alumina. The solution was evaporated to dryness, and the dry mass treated with alcohol, which dissolved the acetite of potassa. The residuum, amounting to 58·75 parts, was dissolved in water; and, being treated with muriate of barytes, fifteen parts of sulphate of barytes precipitated, indicating the presence of about 0·5 of sulphuric acid, 0·75 sulphate of potassa. The remaining fifty-eight parts were muriate of potassa, indicating about twenty-one parts of muriatic acid.

Ores of mercury.—We have very few exact analyses of the ores of mercury, owing, perhaps, to the facility with which the mercury is extracted from them by distillation.

1. Native mercury and amalgam may be dissolved in nitric acid. The gold, if any be present, remains in the state of powder, and may be estimated by its weight. The affusion of water precipitates bismuth. Common salt precipitates the silver and part of the mercury; but the latter may be redissolved by a sufficient quantity of water, or, which is far better, of oxy-muriatic acid, while the muriate of silver remains insoluble. Lastly, the mercury may be precipitated by sulphate of iron, and estimated.

2. Native cinnabar may be treated with a mixture of three parts muriatic and one nitric acid, which dissolves the mercury, and leaves the sulphur. The mercury may then be estimated, as the last.

3. Hepatic mercurial ore has not been analysed. It may be attempted as in No. 2; or by dissolving it in nitric acid.

4. Muriate of mercury may be digested in muriatic acid till the whole is dissolved. Muriate of barytes precipitates the sulphuric acid, 100 parts of which are equivalent to 186 of sulphate of mercury; and, the proportion of this salt being known, we have that of muriate.

Ores of copper.—1. Native copper sometimes contains gold, silver, or iron. It may be dissolved in nitric acid; the gold remains in the state of a blackish, or rather violet-colored powder; the silver may be separated by a polished plate of copper (or precipitated from a portion of the solution by common salt); the iron may be separated by boiling the solution to dryness, and treating the residuum with water. By this process, the nitrate of iron is decomposed; the oxide of iron remains, while the water dissolves the nitrate of copper. This salt may be decomposed by boiling it with potassa: the precipitate, dried in a red heat, is black oxide of copper: 100 parts of it denote eighty of metallic copper.

2. Sulphuret of copper may be dissolved in diluted nitric acid. Part of the sulphur remains unaltered, and may be estimated by weighing it, and burning it off. Part is acidified, and may be precipitated by nitrate of barytes; 100 parts of the dried precipitate indicating 14·5 of sulphur. By evaporation to dryness, and solution of water, the iron is separated; and the copper

may be estimated as in No. 1; or muriatic acid may be used instead of nitric; but in that case it is more difficult to obtain a complete solution.

3. Gray copper ore was analysed by Klaproth thus: 300 parts of it were digested with four times their weight of nitric acid. This operation was repeated, and the two acid liquids mixed. The undissolved residuum was 188 parts. The nitric solution was green, and when common salt was added muriate of silver precipitated. The solution being now supersaturated with ammonia, 9·5 parts of a flaky red precipitate were obtained; which was found to be composed of silica, alumina, and iron by dissolving it in muriatic acid, and proceeding according to the rules laid down in the second chapter. A polished iron plate precipitated from the nitric solution sixty-nine parts of copper. The 188 parts residuum were boiled with six times their weight of muriatic acid; 105·5 parts remained, which were sulphur and silica. The muriatic acid solution being concentrated, yielded a little muriate of silver. Being diluted with a large portion of water, a white powder precipitated, which weighed 97·5 parts, and was oxide of antimony.

4. Red copper ore has only to be dissolved in muriatic acid, and the copper precipitated by a plate of iron: eighty-eight parts of the precipitated copper being equivalent to 100 of the orange oxide, of which the ore is composed.

5. The analysis of the oxides and carbonates of copper scarcely requires any remarks. The water and carbonic acid must be estimated by distillation in close vessels, and collecting the products. The ore may then be dissolved in nitric acid, and its copper ascertained as above.

6. Arseniate of Copper was thus analysed by Mr. Chenevix: the ore was dissolved in diluted nitric acid, and nitrate of lead poured in. The solution was evaporated till a precipitate began to appear, and then mixed with alcohol. Arseniate of lead precipitated: 100 parts of this salt indicate thirty-three of arsenic acid. The copper was separated from the nitric acid by boiling it with potass.

VI. *Ores of iron.*—Notwithstanding the great variety of iron ores, they may all, as far as analysis is concerned, be arranged under three heads: viz. 1. Sulphurets; 2. Oxides; and 3. Salts.

1. Pyrites, or sulphureted iron, may be treated repeatedly with boiling nitric acid, till the sulphur is acidified. Muriatic acid is then to be added, and the digestion continued till the whole be dissolved. Muriate of barytes is then to be added, to precipitate the sulphuric acid; 100 of the dried precipitate indicates 14·5 of sulphur. If the solution contains only iron, it may be precipitated by carbonate of soda, calcined to redness and weighed. But, if earths or manganese be present, we must proceed by the rules laid down in the second chapter.

2. If the oxides of iron be pure, i. e. contain nothing but iron, we have only to dissolve them in muriatic acid, and precipitate them as above. But it is very seldom that ores possess this degree of purity. The iron is usually combined with manganese, alumina, silica, or all these together. The analyses are to be conducted exactly by the rules in the second chapter.

3. The sparry iron ore may be analysed in the same manner, excepting only that the carbonic acid must be separated by distillation or solution in close vessels, and estimated.

4. Arseniate of iron was analysed by Mr. Chenevix thus: 100 parts of it were boiled with potass till the arsenic acid was separated. Nitrate of lead was mixed with the solution; 100 parts of the solution indicated thirty-three of arsenic acid. That portion of the ore which eluded the action of the potass was treated with muriatic acid; the undissolved residuum was silica. The muriatic acid was supersaturated with ammonia. The iron precipitated, but the copper was dissolved by the ammonia.

VII. *Ores of tin.*—For the method of analysing the ores of tin we are solely indebted to Klaproth.

1. The sulphuret of tin was thus analysed by Klaproth: 120 parts of the ore were digested with nitro-muriatic acid: forty-three parts remained undissolved. Of these, thirty burnt away with a blue flame, and were sulphur; of the remaining thirteen, eight dissolved in nitro-muriatic acid: the undissolved five were heated with wax, and yielded a grain of iron attracted by the magnet. The rest was a mixture of alumina and silica. The nitro-muriatic solution was completely precipitated by potass, and the precipitate redissolved in muriatic acid. A cylinder of tin precipitated forty-four parts of copper from this solution, and lost itself eighty-nine parts of its weight. A cylinder of zinc precipitated 130 parts of tin; so that, deducting the eighty-nine parts of tin dissolved during the precipitation of the copper, forty-one remained for the tin contained in the ore.

2. Tinstone was thus analysed by Klaproth: 100 parts of the ore were heated to redness, with 600 parts of potass in a silver crucible; and, the mixture being treated with warm water, eleven parts remained undissolved. These eleven, by a repetition of the treatment with potass, were reduced to two and a quarter. This small residuum dissolved in muriatic acid. Zinc precipitated from the solution one half part of tin, and the prussian alkali gave a blue precipitate, which indicated one-fourth part of iron. The alkaline solution was saturated with muriatic acid; a white precipitate appeared, but was redissolved by adding more acid. The whole was precipitated by carbonate of soda. The solution, which had a yellowish color, was re-dissolved in muriatic acid; and, a cylinder of zinc being inserted into the solution, seventy-seven of tin were obtained, indicating nearly ninety-eight parts oxide of tin.

VIII. *Ores of lead.*—1. Sulphuret of lead usually contains a little silver, and sometimes also antimony and zinc. It may be treated with diluted nitric acid, which leaves only the sulphur undissolved, the weight of which is to be taken, and its purity determined by combustion. If antimony be present, it will either remain in the state of a white oxide, or, if dissolved, will be precipitated by diluting the solution with water. Muriatic acid is to be added, and the solution evaporated till it is reduced to a small portion. Muriate of lead and of silver precipitate. The

first of these may be dissolved in boiling water; the second remains insoluble. Westrum separated the muriate of silver, by digesting the precipitate with ammonia. The liquid from which the muriates are separated may contain iron, zinc, copper. The iron may be precipitated by ammonia added in excess: the copper by a plate of zinc: the zinc by carbonate of soda, reduced to the metallic state and weighed, subtracting what had been separated from the plate of zinc.

2. Plumbiferous antimoniated silver ore was thus analysed by Klaproth: it was digested with seven times its weight of nitric acid, by which part was dissolved. The residuum was treated repeatedly with muriatic acid, which was poured off while boiling hot. What remained undissolved was sulphur mixed with a little silica. Common salt was added to the nitric solution: two precipitates appeared; 1. A heavy fleaky one, which was muriate of silver; 2. Acicular crystals of muriate of lead. These crystals were dissolved in water, and the solution added to the nitric solution. From this solution, sulphate of soda precipitated a heavy white powder, which was sulphate of lead. Lastly, ammonia afforded a precipitate, which was a mixture of iron and alumina. The muriatic solution being concentrated, crystals of muriate of lead appeared; the concentration was continued as long as any crystals formed. The residuum, being diluted with water, gave a white precipitate, which was oxide of antimony.

3. The bismuthic silver ore was analysed by Klaproth in nearly the same manner.

4. Carbonate of lead may be dissolved in nitric acid, collecting and estimating the carbonic acid. By boiling the solution, the iron and antimony (if present) will be separated, and may be estimated by solution in muriatic acid; precipitating the antimony by water, and the iron by ammonia. From the nitric solution the lead may be precipitated by sulphuric acid, and the earth may be examined by the rules laid down in the second chapter.

5. Phosphate of lead may be dissolved in boiling muriatic acid. The solution is to be diluted with water till the crystals of muriate of lead are dissolved; being then saturated with ammonia, the lead and iron are precipitated. Dissolve the precipitate in muriatic acid, evaporate to dryness, and treat the dry mass with alcohol. The muriate of iron is dissolved; but the muriate of lead remains. Finally, drop lime water into the ammoniacal solution, as long as any precipitate appears. That precipitate indicates the proportion of phosphoric acid.

6. Arseniate of lead has not been analysed. It might be treated with an alkali which would separate the lead. This metallic precipitate is then to be redissolved in nitric acid, and analysed by the methods above described. The alkaline arseniate may be dissolved in water, and treated with nitrate of lead; 100 parts of the dry precipitate indicate thirty-three of lead.

7. Molybdate of lead was thus analysed by M. Hatchet: the ore was boiled repeatedly with sulphuric acid, till the acid refused to dissolve any more. The solution contained the molybdic acid. The undissolved powder (sulphate of lead) was boiled for an hour with carbonate of soda, and then washed. Nitric acid now dissolved it, except a little silica. The lead was precipitated from this solution by sulphuric acid; after which ammonia separated a little oxide of iron. The sulphuric acid solution was diluted with sixteen parts of water, and saturated with ammonia; a little oxide of iron gradually precipitated. The solution was now evaporated to dryness, and the mass strongly heated, to separate the sulphate of ammonia. The residuum, repeatedly treated with nitric acid, was converted into yellow molybdic acid.

IX. *Ores of nickel.*—No exact method of analysing the ores of nickel has yet been published.

1. Kupfer nickel may be dissolved in nitric acid, by which the greater part of the sulphur will be separated. The arsenic may be afterwards precipitated by the affusion of water. A plate of iron will expel the copper. Precipitate by potass added in excess, and boil the precipitate, which will separate the arsenic and sulphur completely. Dissolve the precipitate (previously exposed moist for some time to the air) in acetous acid, and add an excess of ammonia. The iron is precipitated; but the cobalt and nickel remain in solution. Evaporate, and the cobalt is deposited; then, by continuing the evaporation to dryness, the nickel is obtained.

2. The arseniate of nickel may be boiled with potass, which separates the acid; the residuum may be analysed as No. 1.

X. *Ores of zinc.*—1. Blende may be treated with diluted nitric acid, which will separate the sulphur, the siliceous gangue, &c. The purity of the sulphur is to be ascertained by combustion, and the residuum analysed in the manner formerly described. Precipitate the nitric solution by soda: redissolve in muriatic acid; precipitate the copper by a plate of iron: separate the iron by an excess of ammonia. The zinc now only remains in the solution, and may be obtained by evaporating to dryness, re-dissolving in muriatic acid, and precipitating by soda.

2. Calamine may be digested in nitric acid and the insoluble residuum boiled with muriatic acid repeatedly; what remains, after dilution with boiling water, is silica. The nitric solution contains zinc, and probably also iron and alumina; evaporate to dryness, re-dissolve, and add an excess of ammonia. The iron and alumina either remain undissolved, or are precipitated, and may be separated by potass. The zinc may be precipitated by an acid, or by evaporation to dryness. The muriatic solution probably contains iron and alumina, which may be precipitated by the rules already laid down.

XI. *Ores of antimony.*—1. Native antimony may be treated with nitric acid, which will oxidate the antimony, and partly dissolve the arsenic. This last metal may be precipitated by concentration and the affusion of water. What remains with the antimony may be dissolved by digestion in boiling water.

2. Sulphuret of antimony is to be treated with nitro-muriatic acid. The sulphur and the muriate of silver, if any be present, will remain. Water precipitates the antimony, sulphuric acid the lead, and ammonia the iron.

XII. *Ores of bismuth.*—Native bismuth may be treated with nitric acid. Repeated concentrations and affusions of water precipitate the bismuth, and perhaps the arsenic; but this last may be redissolved in boiling water. The cobalt remains, and may be examined by the rules laid down in § XV. The same analysis succeeds with the other ores of cobalt. The sulphur, when present, remains undissolved.

XIII. *Ores of tellurium.*—Klaproth dissolved the white gold ore of Fatzbay in nitro-muriatic acid, and added potass in excess to the solution. A brown precipitate remained undissolved, which was a mixture of gold and iron. It was redissolved in nitro-muriatic acid; the gold first precipitated by nitrate of mercury, and then the iron by potass. The potass in the first solution being saturated with muriatic acid the oxide of tellurium precipitated. The other ores may be analysed in the same manner, only the precipipitate occasioned by the potass must be treated according to the metals of which it consists.

XIV. *Ores of arsenic.*—1. Native arsenic may be treated with nitro-muriatic acid. The silver and gold remain; the first in the state of a muriate, the second may be dissolved by nitro-muriatic acid, and precipitated by sulphate of iron. The arsenic may be precipitated by concentrating the nitric solution, and then diluting with water. The iron may then be precipitated by ammonia.

2. The sulphureted ores of arsenic may also be treated with diluted nitro-muriatic acid. The sulphur remains undissolved; the arsenic may be precipitated by concentration and the affusion of water; the iron by ammonia.

3. Oxide of arsenic may be dissolved in sixteen parts of water. The solution displays acid properties, and nitrates of silver and of mercury occasion precipitates in it.

XV. *Ores of cobalt.*—1. White cobalt ore was thus analysed by Tassaert:—To ascertain the proportion of arsenic he treated the ore with diluted nitric acid, and obtained a complete solution. Crystals of white oxide of arsenic were deposited, and by repeated evaporations he separated the whole of the arsenic, and ascertained its weight. He then boiled a new portion of the ore with four times its weight of nitric acid, and thus acidified the arsenic and obtained a solution. This solution was treated with potassa, which retained the arsenic acid, and separated the other bodies. A precipitate of arsenic of cobalt, which had fallen when the nitric solution was diluted with water, was treated with potassa. The residuum, with the precipitate occasioned by the potassa, was dissolved in nitric acid, and ammonia added in excess. Part was retained in solution by the ammonia, but part was precipitated. The precipitate was dissolved in acetous acid, and the solution repeatedly evaporated to dryness. By this process the oxide of iron gradually separated in the form of a red powder. The dissolved part was acetite of cobalt. It was decomposed by the addition of ammonia in excess, which redissolved the cobalt. By these processes the arsenic and iron were separated; the cobalt was retained by the ammonia, and was obtained by evaporation. To ascertain the proportion of sulphur in the ore, a new portion was boiled with nitric acid. On cooling, crystals of white oxide of arsenic were deposited. These being separated, nitrate of barytes was added to the solution; 100 parts of the dried precipitate indicated 14·5 of sulphur. The other ores of cobalt may be analysed nearly in the same way. See § XII.

XVI. *Ores of manganese.*—1. Barytated manganese was treated by Vauquelin with muriatic acid; oximuriatic gas passed over, and the whole was dissolved except a little charcoal and silica. The solution, when evaporated, yielded crystals of muriate of barytes. These were separated, and the liquid, evaporated to dryness, yielded a yellow mass soluble in alcohol, and tinging its flame with yellow brilliant sparks. The proportion of barytes was ascertained by precipitating it in the state of a sulphate; the manganese by precipitating it by carbonate of potassa.

2 The gray ore of manganese was treated by the same chemist with muriatic acid; some silica remained undissolved. Carbonate of potassa was added to the solution. The precipitate was at first white, but became black when exposed to the air. It was treated with nitric acid, which dissolved every thing. The nitric solution, when mixed with carbonate of potassa, deposited only carbonate of lime. The black residuum was mixed with sugar, and treated with nitric acid. The solution was complete; therefore no iron was present.

XVII. *Ores of tungsten.*—1. Wolfram was analysed by the Elhuyarts, and by Vauquelin and Hecht, nearly as follows:—The ore was boiled with muriatic acid, and then digested with ammonia alternately till the whole was dissolved. The ammoniacal solution, being evaporated to dryness and calcined, left the yellow oxide of tungsten in a state of purity. The muriatic solutions were mixed with sulphuric acid, evaporated to dryness, and the residuum redissolved in water. A little silica remained. Carbonate of potassa precipitated a brown powder from this solution. This powder was treated with boiling nitric acid repeatedly till the iron which it contained was oxidated to a maximum. It was then digested in acetous acid, which dissolved the manganese, and left the iron. Finally the manganese was precipitated by an alkali.

2. Tungsten of lime may be treated with nitro-muriatic acid till every thing soluble is taken up. The residuum is yellow oxide of tungsten. Its purity may be tried by solution in ammonia. The nitro-muriatic solution contains lime, and perhaps a little iron and alumina. It may be examined by the rules laid down in the second chapter.

XVIII. *Ores of molybdenum.*—Molybdena may be treated with nitric acid, and successively boiled upon it till it is converted into a white powder. This powder, washed and dried, is molybdic acid. The liquid obtained by washing the acid, on the addition of potassa, deposits some more molybdic acid. This being separated, muriate of barytes is to be dropt into it as long as any precipitate appears: 100 parts of this precipitate indicate 14·5 of sulphur.

XIX. *Ores of uranium.*—1. Pechblende, or the black ore of uranium, was dissolved by Klaproth

in nitric acid. The undissolved part is a mixture of silica and sulphur. By evaporating the solution nitrate of lead was precipitated; then nitrated uranium in crystals. The solution being now evaporated to dryness, and treated again with nitric acid, left the iron in the state of red oxide.

2. Uranitic ochre may be treated with nitric acid, which dissolves the uranium, and leaves the iron. The purity of the iron may be tried by the rules already laid down.

3. Green mica was dissolved by Klaproth in nitric acid, and ammonia added in excess to the solution. The oxide of uranium was precipitated; that of copper retained.

XX. *Ores of titanium.*—1. The ores of titanium, reduced as usual to a fine powder, are to be fused with potassa or its carbonate. The melted mass is then to be dissolved in hot water. A white precipitate gradually appears, which is the white oxide of titanium. This is all that is necessary to analyse the first species.

2. But when iron and silica are present the following method of Chenevix may be adopted:—Saturate the alkaline solution with muriatic acid; white oxide of titanium precipitates. Separate the precipitate, and evaporate the solution to dryness. Redissolve the residuum in water. The silica remains behind. Precipitate the solution by an alkali; add the precipitate to the whole oxide obtained, and dissolve the whole in sulphuric acid. From this solution phosphoric acid precipitates the titanium, but leaves the iron.

3. The third species, which contains lime and no iron, is to be fused with potassa, dissolved in muriatic acid, and the silica separated in the usual way. After this the titanium is first to be separated from the muriatic solution by ammonia; and afterwards the lime by an alkaline carbonate.

XXI. *Ores of chromum.*—1. Vauquelin analysed the chromate of lead thus:—When boiled with a sufficient quantity of carbonate of potassa, a lively effervescence takes place; the acid combines with the potassa, and the carbonate of lead is formed, and remains undissolved. It may be dissolved in nitric acid, and its quantity ascertained by precipitation with sulphuric acid. Or the chromate may be treated with muriatic acid; muriate of lead precipitates, and chromic acid remains in solution. This process must be repeated till the whole of the ore is decomposed. There remains in solution chromic acid, mixed with a little muriatic, which may be separated by oxide of silver.

2. Tassaert analysed the chromate of iron as follows:—It was melted with eight times its weight of potassa in a crucible. The resulting mass dissolved in water except a brown powder. This residuum was treated with muriatic acid, which dissolved a part of it. The residuum was treated as at first with potassa and muriatic acid, till the whole was dissolved. The alkaline solution contained the chromic acid; the muriatic solution the iron, still mixed with a little chromum. It was precipitated by potassa, and the precipitate boiled with that alkali, to separate the whole of the chromic acid What remained was pure oxide of iron. The chromic solutions were saturated with nitric acid, and mixed with nitrate of lead. The resulting precipitate indicated the proportion of chromic acid; for 100 parts of chromate of lead indicate about thirty-five of chromic acid.

The method of analysing the different ores with precision being ascertained, we have it in our power to obtain the metals in a state of purity.

1. *Gold.* To obtain pure gold we have only to dissolve the gold of commerce in nitro-muriatic acid, and precipitate the metal by dropping a very diluted solution of sulphate of iron; the powder which precipitates, after being well washed and dried, is pure gold.

2. *Platinum* can scarcely be obtained perfectly pure in the metallic state, at least in any considerable quantity; because a sufficient heat for melting it cannot be obtained. But its oxide may be procured quite pure from the muriate of platinum and ammonia. This salt is to be decomposed by a violent heat, and the residuum, if necessary, may be redissolved in nitro-muriatic acid, and precipitated with soda.

3. *Silver.*—Dissolve the silver of commerce in nitric acid, and precipitate with a diluted solution of sulphate of iron. The precipitate is pure silver. Or precipitate with common salt; form the precipitate into a paste with soda; put it into a crucible lined with soda, and fuse it with a brisk heat. This process gives a button of pure silver.

4. *Mercury* may be obtained pure by distilling a mixture of two parts cinnabar, and one part iron filings, in an iron retort. The mercury comes over, and the sulphuret of iron remains; or the oxy-muriate of mercury may be decomposed by ammonia, and the precipitate heated either by itself or mixed with oil.

5. *Copper* may be dissolved in muriatic acid, and the copper precipitated by a polished plate of iron: or the black oxide of copper, obtained by decomposing cuprated ammonia, may be melted with its own weight of pounded glass and pitch.

6. *Iron* can scarcely be obtained perfectly free from carbonate. The processes described in a former part of this work furnish it as pure as it can be procured. See Iron.

7. *Tin* may be obtained pure by solution in strong nitric acid: the white oxide of tin is formed, which is insoluble. Let it be digested first with muriatic acid, and afterwards with aqua regia. Mix the oxide, thus purified, with its weight of pitch and a little borax, and melt it in a crucible.

8. *Lead* may be dissolved in nitric acid, and precipitated by sulphate of soda; wash the precipitate, and melt it in a crucible with two and a half times its weight of black flux.

9. *Nickel* may be obtained pure from kupfer nickel, by roasting the ore previously mixed with charcoal; dissolving it in nitric acid; evaporating the solution to dryness; redissolving it in water; precipitating by potass; and boiling the precipitate with potass. The precipitate is then to be edulcorated, dissolved in acetous acid, the solution evaporated to dryness, re-dissolved in water, and precipitated by ammonia in excess, which redissolves the oxides of cobalt and nick-

el. By evaporating this solution the cobalt is precipitated, and the solution becomes blue. This last solution, evaporated to dryness, gives pure oxide of nickel. Form this oxide into a paste with oil; mix it with two or three parts of black flux, and put it into a crucible, covering it up with borax and common salt. Heat the crucible violently for an hour and a half in a smith's forge. A button of pure nickel is obtained.

10. *Zinc* may be dissolved in sulphuric acid, and a plate of zinc allowed to remain for a considerable time in the solution. It is then to be filtered, and the zinc to be precipitated with soda. The precipitate, edulcorated and dried, is to be mixed with half its weight of pure charcoal, and distilled in an earthenware retort. The zinc is found pure in the neck of the retort.

11. *Antimony* may be dissolved in nitro-muriatic acid, and precipitated by the affusion of water. The precipitate is to be mixed with twice its weight of tartar, and fused in a crucible. A button of pure antimony is obtained.

12. *Bismuth* may be dissolved in nitric acid, and precipitated by water. The edulcorated precipitate, formed into a paste with oil, and rapidly fused with black flux, gives a button of pure bismuth.

13. *Tellurium* was obtained pure by Klaproth by forming its oxide into a paste with oil, and heating it to redness in a retort. The metal was rapidly revived.

14. *Arsenic*, in the state of white oxide, may be dissolved in muriatic acid, precipitated by the affusion of water, redissolved and a plate of zinc inserted into the solution, mixing with it at the same time a little alcohol. The arsenic is precipitated in the metallic state.

15. *Cobalt* ores ought to be roasted for some time, adding charcoal or oil to favor the evaporation of the arsenic. They are then to be dissolved in nitric acid, the solution evaporated to dryness, and redissolved in water. The solution is to be precipitated by potass, and the precipitate boiled with that of alkali. It is then to be edulcorated, dissolved in acetous acid, the solution evaporated to dryness, and redissolved in water. Precipitate by ammonia, and redissolve the precipitate in ammonia. Evaporate the ammoniacal solution to dryness. Mix the oxide thus obtained with oil and black flux; pour it into a crucible; cover it with borax; and expose it for an hour and a half to the heat of a forge. A pure button of cobalt is obtained.

16. *Manganese*.—Digest the black oxide of manganese repeatedly in nitric acid; then mix it with sugar; and dissolve it in sugar. Filter the solution; precipitate by an alkali; form the white oxide thus obtained into a paste with oil; and put it into a crucible well lined with charcoal. Expose the crucible for an hour to the strongest heat of a forge.

17. *Tungsten* was obtained by Elhuyart by heating the yellow oxide violently in a crucible lined with charcoal; but this process has not succeeded with other chemists.

18. *Molybdenum* may be obtained by forming molybdic acid into a paste with oil, and heating it violently in a crucible lined with charcoal.

19. *Uranium* is procured by forming the yellow oxide of that metal into a paste with oil, drying it in a moderate heat, putting it into a crucible lined with charcoal, with a little lamp-black strewed over it. After luting on the cover, it is to be heated, at first gently, and then violently, for three-quarters of an hour.

20. *Titanium*, in a very small proportion, was obtained in the metallic state by mixing together 100 parts of the red oxide of the metal, fifty parts of borax, and five parts of charcoal, and forming the mixture into a paste with oil. This paste was put into a crucible lined with charcoal, and exposed for an hour and a half to the violent heat of a forge.

21. *Chromum* was obtained by Vauquelin, in the metallic state, by putting a portion of chromic acid into a charcoal crucible, enclosed in a common crucible lined with charcoal, and exposing it for an hour to the violent heat of a forge.

For the phenomena of the phosphorescence of minerals, see our article LIGHT.

We have now to present to the reader an arrangement of the principal mineral substances with which this science is conversant; and cannot better accomplish the task than by transcribing the Tabular View of simple minerals, contained in professor Cleveland's Elementary Treatise. The divisions into species and the nomenclature of the species are, he observes, as strictly chemical as the present state of mineralogical knowledge will permit. In the class of earthy compounds, an accurate division into genera is impracticable. An attempt has therefore been made to arrange the species of this class, in some degree, according to their composition, as far as that can be ascertained from the results of chemical analysis. In other words, those minerals which most resemble each other in the results of their analysis, are collected into the same group. We are hereby enabled to determine how far those minerals which appear to be composed of the same ingredients, united in different proportions, resemble each other in their external characters. In forming these groups, the latest analyses of the most experienced chemists have been employed, and principally those made by Klaproth, Vauquelin, and Chenevix. It has also been an object to select analyses made on the purest crystallised specimens. In general, no ingredient has been considered essential which does not occur in at least five per cent. in specimens apparently pure; while, at the same time, some ingredients, which occur in greater proportions in specimens obviously impure, have been rejected as accidental. After all, it must be obvious that this arrangement of the earthy minerals is liable to various alterations, in proportion as chemical analysis becomes more correct.

In this Tabular View, subspecies, varieties, and subvarieties, are distinguished from each other by a different type, and by their position in the column: a number of species recently discovered, and concerning which little is yet known, are alphabetically arranged in an appendix to the earthy class: those species which have never been analysed are marked by an asterisk. The place of such minerals, when not contained in

the appendix, is determined merely by some external analogies. Subvarieties, though included in the Tabular View, are not numbered in the descriptions.

We have only to add that it is amongst the most pleasing portions of our duty to acknowledge important aid in this walk of science from the New World. Thus commenced the truly noble career of the United States. During the war that achieved her independence, she taught us electricity; and her well ascertained and well defended liberty will increasingly enable her, we do not doubt, not only to take the lead, as she does, in all the scientific pursuits of her own hemisphere, but to yield back to Europe 'a full reward' for all the early lessons of civilisation and science she received from us. Her most distinguished sons, at any rate, are always most ready to remember these, as, with feelings far removed from jealousy, we deem it imperative upon us thus to acknowledge this practical kind of return.

TABULAR VIEW.

The species printed in Italics have not hitherto been observed in crystals, nor even with a crystalline structure.—Substances enclosed by a parenthesis, in the column of subspecies, are appendices to the species or subspecies.

Class I.—SUBSTANCES NOT METALLIC, COMPOSED ENTIRELY, OR IN PART, OF AN ACID.

This class contains four orders. In the first order the acid is free or not combined; in the second it is combined with an alkali; in the third with an earth or earths; and in the fourth with both an alkali and an earth. Hence the presence of an acid, provided it be not united to a metallic base, characterises this class.

Order I.—Acids not combined.

The base of the acid determines the genus. All the species in this order have oxygen, as a common ingredient, so combined with a base as to produce an acid.

Genus I.

Species 1. Sulphuric acid.
2. *Sulphurous acid.*

Genus II.

1. *Muriatic acid.*

Genus III.

1. *Carbonic acid.*

Genus IV.

1. Boracic acid

Order II.—Alkaline salts.

These salts are composed of an alkali, united to an acid. Hence an alkali, so combined as to form a salt, characterises this order. Each alkali designates a genus.

Genus I.—*Ammonia.*

1. Sulphate of ammonia.
2. Muriate of ammonia.

Genus 2.—*Potassa.*

1. Nitrate of potassa.

Genus III.—*Soda.*

1. Sulphate of soda.
2. Muriate of soda.
3. Carbonate of soda.
4. Borate of soda.

Order III.—Earthy Salts.

These consist of an earth or of earths, united to an acid. Hence an earth, so combined as to form a salt, characterises this order. Each genus is determined by the earth it contains.

Genus I.—*Barytes.*

Species. Subspecies. Varieties and Subvarieties.

1. Sulphate of barytes.
lamellar.
curved.
crested.
columnar.
radiated.
fibrous.
concreted.
granular.
compact.
earthy.
fetid.
2. Carbonate of Barytes.

Genus II.—*Strontian.*

1. Sulphate of strontian.
foliated.
fibrous.
calcareous.
2. Carbonate of strontian.
3. Barystrontianite.

Genus III.—*Lime.*

1. Carbonate of lime.
Calcareous spar.
crystallised.
laminated.
granular.
fibrous.
Satin spar.
compact.
earthy.
Blue Vesuvian.
Chalk.
Agaric mineral.
Fossil farina
concreted.
Oolite.
Pisolite.
Calcareous sinter.
Stalactite.
Alabaster.
Calcareous tufa.
incrusting
Argentine.
Aphrite.
magnesian.
crystallised.
Miemite.
Dolomite.
columnar.
Magnesian limestone.
Gurhofite.
Brown spar.
siliceous.
Madreporite.
fetid.
bituminous.
ferruginous.
Calp.

Species. Subspecies. Varieties and Subvarieties.

Marl.
indurated.
Septaria.
earthy.
Bituminous marlite.
2. Arragonite.
fibrous.
coralloidal.
3. Phosphate of lime.
Apatite.
Asparagus stone.
fibrous.
massive.
pulverulent.
siliceous.
4. Fluate of lime.
Fluor spar.
massive.
compact.
earthy.
argillaceous.
fetid.
5. Sulphate of lime.
Selenite.
massive.
acicular.
Gypsum.
fibrous.
granular.
compact.
branchy.
snowy.
earthy.
Plaster stone.
6. Anhydrous sulphate of lime.
sparry.
granular.
fibrous.
compact.
convoluted.
silico-anhydrous.
7. Siliceous borate of lime.
Botryolite.
8. Arseniate of lime.
9. Nitrate of lime.

Genus IV.—*Magnesia.*

1. Sulphate of magnesia.
2. Carbonate of magnesia.
crystallised.
compact.
pulverulent.
3. Borate of magnesia.

Genus V.—*Alumine.*

1. Mellate of alumine.
2. Phosphate of alumine.
3. Subsulphate of alumine.

Order IV.—SALTS WITH AN ALKALINE AND EARTHY BASE.

1. Subsulphate of alumine and potassa.
siliceous.
2. Sulphate of alumine and potassa.
3. Fluate of soda and alumine.
4. Glauberite.
5. Polyhalite.

Class II.—EARTHY COMPOUNDS, OR STONES.

The minerals which belong to this class are composed chiefly of earths, combined with each other; they frequently contain some metallic oxide, and sometimes an alkali, or acid.

Species. Subspecies. Varieties and Subvarieties.

Silex nearly pure.

1. Quartz.
common.
limpid.
smoky.
yellow.
blue.
rose red.
irised.
aventurine.
milky.
greasy.
radiated.
tabular.
granular.
arenaceous.
pseudomorphous.
Amethyst.
Prase.
ferruginous.
yellow.
red.
greenish.
fetid.
Cat's eye.
Chalcedony.
common.
Cacholong.
Carnelian.
Sardonyx.
Plasma.
Siliceous sinter.
Hyalite.
Michaelite.
Heliotrope.
Chrysophrase.
Opal.
precious.
common.
Hydrophane.
Girasol.
Semi-opal.
Menilite.
ferruginous.
(Opalised wood).
Flint.
swimming.
Hornstone.
(Agatised wood).
Silicecalce.
Buhrstone.
Jasper.
common.
striped.
Egyptian.
(Porcellanite.)
Leelite.
(Agate.)

Alumine nearly pure.

2. Sapphire.
perfect.
blue.
violet.
red.
yellow.
green.
limpid.
chatoyant.
asteriated.
Corundum.
Emery.

	Species.	Subspecies.	Varieties and Subvarieties.
Alumine and water.	3. Diaspore.

	88. *Tripoli.*			
			Rotten stone.	
			Polishing slate.	
	89. *Claystone.*			
	90. *Clay.*			
			Kollyrite.	
			Allophane.	
			Lenzinite.	
			Wallerite.	
			Kaolin.	
			Cimolite.	
			adhesive.	
			Potter's.	
				Pipe clay.
				variegated.
				Loam.
			Lithomarge.	
				Mountain soap.
			Fuller's earth.	
			Bole.	
			Reddle.	
			Yellow earth.	
			Umber.	

Appendix.

1. *Amblygonite.
2. *Bergmanite.
3. **Cereolite.*
4. **Chlorophæite.*
5. **Chusite.*
6. **Conite.*
7. *Desmine.
8. Fahlunite.
9. *Freisleben.
10. *Fuscite.
11. *Haydenite.
12. *Helvin.
13. *Humite.
14. **Limbilite.*
15. **Sideroclepte.*
16. *Sphærulite.
17. *Spinellane.
18. *Spinthere.
19. *Thulite.

*Eudialyte.
Gibbsite.
*Gieseckite.

Class III.—COMBUSTIBLES.

	Species.	Subspecies.	Varieties and	Subvarieties.
	1. *Hydrogen gas.*			
			carbureted.	
			sulphureted.	
	2. Sulphur.			
	3. *Bitumen.*			
			Naphtha.	
			Petroleum.	
			Maltha.	
			elastic.	
			Asphaltum.	
		(Retinasphaltum).		
		(Fossil copal)		
		(Hatchetine).		
	4. *Amber.*			
			earthy.	
	5. Diamond.			

Species. Subspecies. Varieties and Subvarieties.

6. Anthracite.
slaty.
granular.
conchoidal.
columnar.
(Mineral charcoal).
7. Graphite.
foliated.
granular.
8. *Coal.*
cannel.
slaty.
coarse.
sooty.
(Dysodile).
9. *Lignite.*
Jet.
brittle.
Bituminous wood.
brown.
earthy.
Aluminous earth.
10. *Peat.*
fibrous.
compact.

Class IV.—ORES.

Genus I.—*Gold.*

1. Native gold.
argentiferous.

Genus II.—*Platina.*

1. Native platina.

Genus III.—*Iridium.*

1. Native iridium.

Genus IV.—*Palladium.*

1. Native palladium.

Genus V.—*Silver.*

1. Native silver.
auriferous.
2. Antimonial silver.
3. Arsenical silver.
4. Sulphuret of silver.
cupreous.
(Silver black).
5. Cupreous seleniuret of silver.
6. Sulphureted antimonial silver.
brittle.
7. *Carbonate of silver.*
8. Muriate of silver.
argillaceous.

Genus VI.—*Mercury.*

1. *Native mercury.*
2. Argental mercury.
3. Sulphuret of mercury.
common
fibrous.
compact.
slaty.
(Bituminous cinnabar).
4. Muriate of mercury.

Genus VII.—*Copper.*

1. Native copper.
2. Sulphuret of copper.
pseudomorphous.
(Black copper).
3. Pyritous copper.
variegated.

Species. Subspecies. Varieties and Subvarieties.

4. Gray copper.
arsenical.
antimonial.
Tennantite.
(White copper).
5. Seleniuret of copper.
6. Red oxide of copper.
foliated.
capillary.
compact.
ferruginous.
7. Carbonate of copper.
blue.
earthy.
green.
fibrous.
compact.
(Copper green).
8. Anhydrous carbonate of copper.
9. Dioptase.
10. Muriate of copper.
sandy.
11. Sulphate of copper.
12. Phosphate of copper.
13. Arseniate of copper.
obtuse octahedral.
acute octahedral.
hexahedral.
prismatic.
fibrous.
earthy.
ferruginous.

Genus VIII.—*Iron.*

1. Native iron.
meteoric.
2. Arsenical iron.
argentiferous.
3. Sulphuret of iron.
common.
capillary.
cellular.
radiated.
cockscomb.
hepatic.
magnetic.
arsenical.
4. Magnetic oxide of iron.
Native magnet.
Iron sand.
earthy.
5. Specular oxide of iron.
micaceous.
6. Red oxide of iron.
scaly.
Red hæmatite.
compact.
ochry.
7. Brown oxide of iron.
scaly.
hæmatitic.
compact.
ochry.
8. *Argillaceous oxide of iron.*
columnar.
granular.
lenticular.
nodular.

Species. Subspecies. Varieties and Subvarieties.

Argillaceous oxide of iron.
common.
jaspery.
Bog ore
(Pitchy iron ore).
(Vitreous black oxide of iron).
(Stilpnosiderite).
(Blue ironstone).
(Hedenbergite).

9. Carbonate of iron.
10. Sulphate of iron.
11. Phosphate of iron.
crystallised.
earthy.
(Green iron earth).
12. Arseniate of iron.
(Skorodite).
13. Chromate of iron.
crystallised.
granular.
amorphous.
14. Muriate of iron.

Genus IX.—*Lead.*

1. *Native lead.*
2. Sulphuret of lead.
common.
granular.
compact.
specular.
striated,
antimonial.
argento-antimonial.
argento-bismuthal.
arsenical.
cobaltic.
3. Oxide of lead.
aluminous.
4. Carbonate of lead.
acicular.
columnar.
earthy.
black.
5. Carbonated muriate of lead.
6. Sulphate of lead.
7. Phosphate of lead.
acicular.
arseniated.
(Blue lead).
8. Arseniate of lead.
reniform.
9. Chromate of lead.
cupreous.
10. Molybdate of lead.
11. Tungstate of lead.

Genus X.—*Tin.*

1. Oxide of tin.
fibrous
2. *Pyritous tin.*

Genus XI.—*Zinc.*

1. Sulphuret of zinc.
yellow.
brown.
black.
fibrous.
2. Red oxide of zinc.
3. Franklinite.
4. Siliceous oxide of zinc.

Species. Subspecies. Varieties and Subvarieties

5. Carbonate of zinc.
compact.
earthy.
cupreous.
6. Sulphate of zinc.

Genus XII.—*Nickel.*

1. Native nickel.
2. Arsenical nickel.
(Black nickel).
3. *Arsenite of nickel.*

Genus XIII.—*Cobalt*

1. Arsenical cobalt.
dull.
2. Gray cobalt.
3. *Sulphuret of cobalt.*
4. *Oxide of cobalt.*
black.
brown.
yellow.
5. Sulphate of cobalt.
6. Arseniate of cobalt.
acicular.
earthy.
slaggy.
argentiferous.

Genus XIV.—*Manganese.*

1. Sulphuret of manganese.
2. Oxide of manganese.
radiated.
argentine.
compact.
earthy.
ferruginous.
3. Siliceous oxide of manganese.
4. Carbonate of manganese.
5. Phosphate of manganese.

Genus XV.—*Arsenic.*

1. Native arsenic.
concreted.
specular.
amorphous.
2. Sulphuret of arsenic.
Realgar.
Orpiment.
3. Oxide of arsenic.

Genus XVI.—*Bismuth.*

1. Native bismuth.
2. Sulphuret of bismuth.
cupreous.
plumbo-cupreous.
3. *Oxide of bismuth.*

Genus XVII.—*Antimony.*

1. Native antimony.
arsenical.
2. Sulphuret of antimony.
radiated.
foliated.
compact.
plumous.
argentiferous.
nickeliferous.
cupreous.
3. Oxide of antimony.
earthy.
(ferruginous).
4. Sulphureted oxide of antimony

Species. Subspecies. Varieties and Subvarieties.

Genus XVIII.—*Tellurium.*

1. Native tellurium.
   auro-argentiferous.
   auro-plumbiferous.

Genus XIX.—*Chrome.*

1. Oxide of chrome.

Genus XX.—*Molybdena.*

1. Sulphuret of molybdena.
2. *Oxide of molybdena.*

Genus XXI.—*Tungsten.*

1. Yellow oxide of tungsten.
2. Calcareous oxide of tungsten.
3. Ferruginous oxide of tungsten.

Genus XXII.—*Titanium.*

1. Red oxide of titanium.
   reticulated.
2. Ferruginous oxide of titanium.
   Menachanite.
   Nigrine.
   Iserine.
   (Crichtonite).
3. Silico-calcareous oxide of titanium.
4. Octahedral oxide of titanium.

Genus XXIII.—*Uranium.*

1. Black oxide of uranium.

Species. Subspecies. Varieties and Subvarieties.

2. Green oxide of uranium.
   crystallised.
   earthy.

Genus XXIV.—*Columbium.*

1. Ferruginous oxide of columbium.
2. Yttrious oxide of columbium.

Genus XXV.—*Cerium.*

1. *Siliceous oxide of cerium.*
2. Allanite.
3. Fluate of cerium.
   neutral.
   Subfluate.
   yttrious.
   (Yttrocerite).

Genus XXVI.—*Selenium.*

Genus XXVII.—*Cadmium.*

We add, in justice to some brilliant discoveries of that philosopher, the following tables, exhibiting the effects of polarised light on various mineral substances, by Dr. Brewster. They appeared in his Edinburgh Philosophical Journal, to which we have to acknowledge those numerous obligations which have rendered its discontinuance a matter of unfeigned regret to us.

I.—List of Absorbing Crystals with One Axis.

Names of crystals.	Color when its axis is in the plane of primitive polarisation.	Color when its axis is perpendicular to that plane.
Zircon	Brownish white	A deeper brown
Sapphire	Yellowish green	Blue
Ruby	Pale yellow	Bright pink
Emerald	Yellowish green	Bluish green
Emerald	Bluish green	Yellowish green
Beryl blue	Bluish white	Blue
Beryl green	Whitish	Bluish green
Beryl yellow green	Pale yellow	Pale green
Rock crystal, almost transparent	Whitish	Faint brown
Rock crystal yellow	Yellowish white	Yellow
Amethyst	Blue	Pink
Amethyst	Grayish white	Ruby red
Amethyst	Reddish yellow	Ruby red
Tourmaline	Greenish white	Bluish green
Rubellite	Reddish white	Faint red
Idocrase	Yellow	Green
Mellite	Yellow	Bluish white
Phospnate of lime (lilac)	Bluish	Reddish
——————— (olive)	Bluish green	Yellowish green
Phosphate of lead	Bright green	Orange yellow
Calcareous spar	Orange yellow	Yellowish white

The property which these crystals possess of absorbing the different tints in different positions of the axis, with regard to the plane of primitive polarisation, does not belong to every specimen. There are many crystals of ruby, sapphire, emerald, &c., which give an ordinary and an extraordinary image of the same color; and, whenever this is the case, they are destitute of the property of absorbing polarised light. These two classes of phenomena are indeed invariably connected, and will ultimately be found to have the same origin.

II.—List of Absorbing Crystals with Two Axes.

	Plane of the resultant axes in the plane of primary polarisation.	Plane of the resultant axes perpendicular to the plane of primary polarisation.
Topaz blue	White	Blue
—— green	White	Green
—— grayish blue	Reddish gray	Blue
—— pink	Pink	White
—— pink yellow	Pink	Yellow
—— yellow	Yellowish white	Orange
Sulphate of barytes		
—— yellowish purple	Lemon yellow	Purple
—— yellow	Lemon yellow	Yellowish white
—— orange yellow	Gamboge yellow	Yellowish white
Kyanite	White	Blue
Dichroite	Blue	Yellowish white
Cymophane	Yellowish white	Yellowish
Epidote olive green	Brown	Sap green
—— whitish green	Pink white	Yellowish white
Mica	Reddish brown	Reddish white

III.—The following Table shows the Characters of the Tints in Crystals with Two Axes which have not been examined in every azimuth.

	Axis of prism in the plane of primitive polarisation.	Axis of prism perpendicular to the plane of primitive polarisation.
Mica	Blood red	Pale greenish yellow
Acetate of copper	Blue	Greenish yellow
Muriate of copper*	Greenish white	Blue
Olivine	Bluish green	Greenish yellow
Sphene	Yellow	Bluish
Nitrate of copper	Bluish white	Blue
Chromate of lead	Orange	Blood red
Staurotide	Brownish red	Yellowish white
Augite	Blood red	Bright green
Anhydrite	Bright pink	Pale yellow
Axinite	Reddish white	Yellowish white
Diallage	Brownish white	White
Sulphur	Yellow	Deeper yellow
Sulphate of strontites	Blue	Bluish white
—— cobalt	Pink	Brick red
Olivine.	Brown	Brownish white

In the last eight crystals of the preceding table the tints are not given in relation to any fixed line.

IV.—The following Table contains the Characters of the Two Pencils in Crystals the number of whose axes I have not yet determined.

Phosphate of iron	Fine blue †	Bluish white
Actinolite	Green	Greenish white
Precious opal	Yellow	Lighter yellow
Serpentine	Dark green	Lighter green
Asbestos	Greenish	Yellowish
Blue carbonate of copper	Violet blue	Greenish blue
Octohedrite (*one axis*).	Whitish brown	Yellowish brown

MINERVA, ATHENA, or PALLAS, in Pagan worship, the goddess of sciences and of wisdom, who sprung completely armed from Jupiter's brain; and on the day of her nativity it rained gold at Rhodes. She disputed with Neptune the honor of giving a name to the capital of Cecropia, when they agreed that whosoever of them should produce what was most useful to mankind, should have that advantage. Neptune, with a stroke of his trident, formed a horse; and Minerva caused an olive to spring from the ground, which was judged by the unanimous voice of the gods to be the most useful, from its being the symbol of peace; whereupon she gave her name Athenæ to the city, and became its tutelar goddess. Minerva changed Arachnè into a spider, for pretending to excel her in making tapestry. She fought the giants; favored Cadmus, Ulysses, and other heroes; and refused to marry Vulcan, choosing rather to live in a state of celibacy. She also deprived Tiresias of sight, turned Medusa's locks into snakes, and performed several other exploits. Minerva is usually represented by the poets, painters, and sculptors, completely armed, with a composed but agreeable countenance, bearing a golden breast-plate, a spear in her right hand, and her ægis or shield in the left, on which is represented Medusa's head encircled with snakes, and her helmet usually entwined with olives. Minerva had several temples both in Greece and Italy. The usual victim offered her was a white heifer, never yoked. The animals sacred to her were the cock, the owl, and the basilisk.

MINERVÆ ARX, MINERVÆ CASTRUM, MINERVIUM, or Templum Minervæ, a citadel, temple, and town on the Ionian Sea, beyond Hydrus; seen a great way out at sea, now called Castro, a town of Otranto in Naples. Long. 19° 25′ E., lat. 46° 8′ N.

MINERVÆ PROMONTORIUM, in ancient geography, the seat of the Sirens, a promontory of Italy, in the Sinus Paestanus, the south boundary of Campania on the Tuscan coast; so called from a temple of Minerva on it: situated south of Surrentum, and therefore called Surrentinum: now Capo della Minerva, on the west coast of Naples, over against the island Capri.

MINERVALIA, in Roman antiquity, festivals celebrated in honor of Minerva; in March the scholars had a vacation, and usually made a present to their masters, called from this festival Minerval.

MIN'GLE, *v. a.*, *v. n.* & *n. s.* Sax. mengen; Teut. and Belg. *mengen, mengelen*; Goth. *meinga*. To mix, unite, compound; hence to join dissimilar things; to confuse; to contaminate: as a neuter verb, to be mixed or united with: as a substantive it is used as synonymous with mixture, medley, confused accumulation or mass.

Alcimus had defiled himself wilfully in the times of their *mingling* with the Gentiles. 2 *Mac.* xiv. 13.

Ourself will *mingle* with society,
And play the humble host.
Shakspeare. Macbeth.

Trumpeters,
With brazen din blast you the city's ear,
Make *mingle* with our rattling tabourines. *Id.*

Sulphurous and nitrous foam
They found, they *mingled*, and with subtle art,
Concocted and adusted, they reduced
To blackest grain. *Milton.*

To confound the race
Of mankind in one root, and Earth with Hell
To *mingle* and involve. *Id.*

Neither can I defend my Spanish Fryar; though the comical parts are diverting, and the serious moving, yet they are of an unnatural *mingle*.
Dryden's Dufresnoy.

Lament with me! with me your sorrows join,
And *mingle* your united tears with mine! *Walsh.*

Nor priests, nor statesmen,
Could have completed such an ill as that,
If women had not *mingled* in the mischief.
Rowe.

She, when she saw her sister nymphs, suppressed
Her rising fears, and *mingled* with the rest.
Addison.

The best of us appear contented with a *mingled* imperfect virtue. *Rogers's Sermons.*

Our sex, our kindred, our houses, and our very names, we are ready to *mingle* with ourselves, and cannot bear to have others think meanly of them.
Watts's Logic.

To have fought together in such a cause—to have *mingled* banners, and to have *mingled* blood in battles of such interests, and leading to such results, must undoubtedly cement an eternal union between the British and Portuguese nations. *Canning.*

MINGRELIA, a part of Western Georgia, in Asia, anciently called Colchis; bounded on the east by Iberia, or Georgia properly so called; on the west by the Euxine Sea; on the south by Armenia, and part of Pontus; and on the north by mount Caucasus. It is watered by many rivers, particularly the Corex, the Hippus, the Cyaneus, the Charistus, the Phasis, where the Argonauts landed, the Absarus, the Cissa, and the Ophis, all running into the Euxine Sea. The whole kingdom of Colchis was in ancient times very pleasant and fruitful, as it is still where duly cultivated; abounding in all the necessaries of life; and was enriched with many mines of gold, which gave occasion to the fable of the Golden Fleece and the Argonautic expedition, so much celebrated by the ancients. Sir John Chardin tells us, that this country extends above 100 miles in length and sixty in breadth; being not nearly so extensive as the ancient Colchis, which reached from the frontiers of Iberia or Georgia Proper, west to the Palus Mæotis: that it is beautifully diversified with hills, mountains, valleys, woods, and plains, but badly cultivated: that besides vines, all kinds of fruits found in England grow wild, but tasteless for want of culture: that there are many rivers which rise in mount Caucasus, particularly the Phasis, now called the Rione: that the country abounds with beeves, hogs, wild boars, stags, partridges, pheasants, and quails: that falcons, eagles, pelicans, lions, leopards, tigers, wolves, and jackals, breed on mount Caucasus, and sometimes greatly annoy the country: that the people are generally handsome, the men strong and well made, and the women very beautiful; but both sexes very debauched: that they marry their nieces, aunts, or other near relations, indifferently; and take as many wives and concubines as they please: that they not only sell their children, but even murder them, or bury them alive, when they find it difficult to bring them up: that

they use a sort of paste, made of a plant called gom, instead of bread; but that of the superior ranks consists of wheat, barley, or rice: that the gentry have an absolute power over their vassals, extending to life, liberty, and estate: that their arms are bows and arrows, lances, sabres, and bucklers; that they eat sitting cross-legged upon a carpet, like the Persians; but the poorer sort upon a mat or bench: that the country is very thin of inhabitants, no fewer than 12,000 being sold yearly to the Turks and Persians: that the principal commodities exported from it are honey, wax, hides, castor, skins, flax-seed, thread, silk, and linen cloth; but there are now no gold or silver mines, and very little money: that the annual revenue of the viceroy amounts to about 20,000 crowns: that the inhabitants call themselves Christians; but that they and their priests are altogether ignorant of the doctrines of Christianity: that their bishops are rich, have a great number of vassals, and are clothed in scarlet and velvet: and that their service is according to the rites of the Greek church, with a mixture of Judaism and Paganism. The cities of most note in this country in ancient times were Pityus; Dioscurias, or Dioscorias, so called from Castor and Pollux, by whom it is said to have been founded, and who in Greek are styled Διοσκυροι, now called Savatapoli; Aea on the Phasis, supposed to be Hupolis; Phasis, so called from the river; Cyta, at the mouth of the Cyaneus, the birthplace of Medea, called thence, by the poets, Cytæis; Saracæ, Zadris, Surium, Madia, and Zolissa. As for modern cities, there are none worthy of a description known to Europeans.

MIN'IATURE, *n. s.* Fr. *miniature;* Span. *miniatura;* Lat. *minio*, to paint with minium. Perhaps, originally, painting with powders mixed with gum and water, first appropriated to small figures: diminutive representation. But see another etymology in the article.

The water, with twenty bubbles, not content to have the picture of their face in large, would in each of these bubbles set forth the *miniature* of them.
Sidney.

The hidden ways
Of nature would'st thou know; 'how first she frames
All things in *miniature?* thy specular orb
Apply to well dissected kernels: lo!
Strange forms arise, in each a little plant
Unfolds its boughs: observe the slender threads
Of first beginning trees, their roots, their leaves,
In narrow seeds described. *Philips.*

If the ladies should once take a liking to such a diminutive race, we should see mankind epitomised, and the whole species in *miniature*: in order to keep our posterity from dwindling, we have instituted a tall club. *Addison's Guardian.*

Here shall the pencil bid its colors flow,
And make a *miniature* creation grow. *Gay.*

MINIATURE PAINTING is a delicate kind of painting, in which the subjects are represented on a very small scale. The word comes from the French mignature, from mignon, fine or pretty, on account of its smallness and delicacy; and it may be ultimately derived from μικρος, small, or minimus, least. Miniature is distinguished from other kinds of painting by the smallness and delicacy of its figures; on which account it requires to be viewed very closely.—As many persons wish to amuse themselves with painting in miniature, who know little or nothing of the principles of drawing or painting, various methods have been invented, such as copying by squares, on oiled paper, &c. Perhaps one of the best mechanical inventions to assist such persons is the mathematical compass called a PENTAGRAPH, which see. See also DRAWING and PAINTING.

For a long time miniature painting was employed upon vellum, paper, &c.; but, in the present improved state of the art, ivory is more used than any of these materials. Yet ivory being a solid substance, and wanting that absorbent surface which constitutes the excellence of vellum, it renders the management of the colors much more difficult and laborious. No tints can be produced by the expeditious mode of washing; but all must be done by dint of labor, by dotting or hatching. Gumming is the next expedient resorted to, to fix the first lays in order to take the subsequent colors; and so on till the work is finished. In conseqence of these difficulties, so perplexing to every artist, miniature painters have of late confined themselves chiefly to portrait painting, and the higher branch of history has been much neglected. This obstacle to historical painting in miniature is now however likely to be done away; Mr. Einsle, an ingenious artist in London, having discovered a method of producing, by a chemical process, a white skinny surface on the ivory, at once smooth and absorbent, so as to unite all the qualities required for washing and painting upon it, in the same manner as on vellum. The colors, when properly ground and mixed up with gum, produce a gloss without the assistance of gumming; and admit of being laid on one lay after another to any depth, without removing those underneath. To the same artist we are indebted for a peculiar preparation of the colors usually employed in miniature painting; which are both superior to the old, and fewer in number. The chief colors made use of for painting in miniature are, carmine; Venice and Florence lake; rose pink; vermilion; red lead; brown red; red orpiment; ultramarine; verditer; indigo; gallstone; yellow ochre; Dutch pink; gamboge; Naples yellow; pale masticot; deep yellow masticot; ivory black; lamp black; true Indian ink; bistre or wood-soot; raw umber; burnt umber; sapgreen; verdigris; and flake white. Most of these colors may easily be prepared by attending to the directions given under the article COLOR-MAKING. But they can all be had ready prepared, in complete sets, from the color shops. Provide an ivory pallet, very smooth, as big as your hand; on one side of which the colors for the carnation, or naked parts of a picture, are to be arranged thus: in the middle put a great deal of white, pretty largely spread; because it is the color most made use of: and upon the edge, from the left to the right, place the following colors at a little distance from the white: Masticot; Dutch pink; orpiment; yellow ochre; green, composed of verditer, Dutch pink, and white, in equal quantities; blue, made of ultramarine, indigo, and white, to a great degree of paleness;

vermilion; carmine, bister, and black On the other side of the pallet, spread some white in the same manner as for the carnation. When draperies, or the like, are to be painted, place near the white the color they are to be made of. To work well in minature, it must be done in a room that has but one window, with a table and desk almost as high as the window. The painter must place himself near it, in such a manner that the light may always come in on the left side, and never forwards or on the right. To lay the color on all parts equally strong, as for a ground, make the mixtures in shells, and put in enough for the thing to be painted; for, if there be not enough, it is a great chance but the color mixed afterwards is too dark or too light. Begin by dead coloring, i.e. by laying the colors on with liberal strokes of the pencil, in the smoothest manner, as the painters do in oil; not giving it all the force it is to have for a finishing. Make the lights a little brighter, and the shades less dark, than they ought to be; because in dotting upon them, as must be done after dead coloring, the color is always fortified, and would at last be too dark. There are several ways of dotting. Some make their dots perfectly round; others a little longish; others hatch by little strokes that cross each other every way, till the work appears as if it had been wrought with dots. This last method is the best, the boldest, and the soonest done: therefore learners ought to use it, and to inure themselves from the first to dot in the plump and the soft way; that is, where the dots are lost, in a manner, in the ground, and only so much appears as is sufficient to make the work seem dotted. The hard and dry way is quite the reverse, and always to be avoided, as it makes the work seem rough and uneven. Study likewise to lose and drown the colors one in another, so that it may not appear where they disjoin; and, to this end, soften or allay the touches with colors that partake of both, so that it may not appear to be the touches which cut and disjoin them. By the word cut is meant what manifestly separates and divides, and does not run in and blend itself with the neighbouring colors; which is rarely practised but upon the borders of drapery. When the pieces are finished, to heighten them a little, and give them a fine air, give, upon the extremity of the lights, small touches with a color yet lighter, which must be gradually lost with the rest. When the colors are dry upon the pallet or in the shells, they must be diluted with water. And when they want gum, which is seen when they easily rub off the hand or the vellum, they must be tempered with gum water instead of pure water, till they are in condition. See PAINTING.

MIN'IKIN, *adj.* & *n. s.*, MIN'IM, *n. s.*, MIN'IMUS. Goth. Belg. and Teut. *min;* Lat. *minus, minimus.* Small, diminutive: any thing or person very small; a dwarf.

Sleepest, or wakest thou, jolly shepherd?
Thy sheep be in the corn;
And for one blast of thy *minikin* mouth,
Thy sheep shall take no harm.
Shakspeare. King Lear.

Get you gone you dwarf;
You *minimus*, of hind'ring knot grass made;
You bead, you acorn. *Id.*

MINIM, a character or note in music, equal in duration to the sixteenth part of a large, one eighth of a long, one fourth of a breve, and one half of a semi-breve

MINIMS, a religious order in the church of Rome, founded by St. Francis de Paula, towards the end of the fifteenth century. Their habit is a coarse black woollen stuff, with a woollen girdle, of the same colors, tied in five knots. They are not permitted to quit their habit and girdle night nor day. Formerly they went barefooted, but are now allowed the use of shoes.

MINIMUM, in the higher geometry, the least quantity attainable in a given case.

MIN'ION, *n. s.* Teut. *minion;* Fr. *mignon;* the root Mr. Thomson thinks is the Gothic *ven* or *min*, affection, love. A favorite; an insignificant or low dependent; a contemptuous cognomen.

Minion, said she; indeed I was a pretty one in those days; I see a number of lads that love you. *Sidney.*

They were made great courtiers, and in the way of *minions*, when advancement, the most mortal offence to envy, stirred up their former friend to overthrow them. *Sidney.*

One who had been a special *minion* of Andromanas, hated us for having dispossessed him of her heart. *Id.*

Go rate thy *minions*;
Becomes it thee to be thus bold in terms
Before thy sovereign? *Shakspeare. Henry VI.*

Edward sent one army into Ireland; not for conquest, but to guard the person of his *minion*, Piers Gaveston. *Davies.*

If a man should launch into the history of human nature, we should find the very *minions* of princes linked in conspiracies against their master. *L'Estrange.*

The drowsy tyrant by his *minions* led,
To regal rage devotes some patriot's head.
Swift.

I speak of the neglected many, whose nerves, whose sinews, whose days, are sold to the *minions* of fortune. *Burns.*

MIN'IOUS, *adj.*, MIN'IUM, *n. s.* Lat. *minium.* Of the color of red lead: red lead.

Some conceive that the Red Sea receiveth a red and *minious* tincture from springs that fall into it. *Brown.*

Melt lead in a broad earthen vessel unglazed, and stir it continually till it be calcinated into a gray powder; this is called the calx of lead; continue the fire, stirring it in the same manner, and it becomes yellow; in this state it is used in painting, and is called masticot or massicot; after this put it into a reverberatory furnace, and it will calcine further, and become of a fine red, which is the common *minium* or red lead: among the ancients *minium* was the name for cinnabar; the modern *minium* is used externally, and is excellent in cleansing and healing old ulcers.

MIN'ISH, *v. a.* From diminish, or Gothic *minn;* Lat. *minus, minuo.* To make small or smaller; to lessen, impair; lop, clip.

Ye shall not *minish* ought from your bricks of your daily task. *Exod.* v. 19.

They are *minished* and brought low through oppression. *Psalm* cvii. 39.

Another law was to bring in the silver of the realm to the mint, in making all clipt, *minished*, or impaired coins of silver, not to be current in payments. *Bacon's Henry VII.*

MIN'ISTER, *n. s., v. a. & v. n.* Fr. *ministre*; Ital. Span. and Port. *ministro*; Lat. *minister*. An agent, attendant, assistant, servant; particularly a servant of God in any of the offices of the church; a servant of the king or state; a member of the administrative government; an official; a delegate: to minister is to supply, give, or afford; and, as a neuter verb, to attend, serve in any office; give supplies: ministerial and ministrant mean, attendant; acting under command or agency; sacerdotal; official: a ministerialist, in political affairs, is an adherent, or writer in favor of an administration: ministral, pertaining to a minister, or a ministry: ministration, agency; operation or influence; intervention; dispensation of God's will; ecclesiastical service: ministry, office; service; particularly of the church; administrative part of a government; business.
MINISTE'RIAL, *adj.*
MINISTE'RIALIST, *n. s.*
MINISTE'RIALLY, *adv.*
MIN'ISTRAL, *adj.*
MIN'ISTRANT,
MINISTRA'TION, *n. s.*
MIN'ISTRY,

His modir seith to the *mynystris*, whatever thing he seye to you, do ye. *Wiclif. Jon.* 2.

Others *ministered* unto him of their substance. *Luke.*

Whether prophecy, let us prophesy according to the proportion of faith; or *ministry*, let us wait on our *ministering*. *Rom.* xii. 7.

Now he that *ministereth* seed to the sower, both *minister* bread for your food, and multiply your seed sown. 2 *Cor.* ix.

Epaphras, a faithful *minister* of Christ. 1 *Col.* i. 7.

You, whom virtue hath made the princess of felicity, be not the *minister* of ruin. *Sidney.*

These speeches of Jerom and Chrysostom plainly allude unto such *ministerial* garments as were then in use. *Hooker.*

Can'st thou not *minister* to a mind diseased,
Pluck from the memory a rooted sorrow,
Raze out the written troubles of the brain? *Shakspeare. Macbeth.*

Rumble thy belly full; spit fire! spout rain!
Nor rain, wind, thunder, fire, are my daughters;
I tax not you, you elements, with unkindness:
But yet I call you servile *ministers*,
That have with two pernicious daughters joined
Your high-engendered battles, 'gainst a head
So old and white as this. *Id. King Lear.*

If wrongfully,
Let God revenge; for I may never lift
An angry arm against his *minister*. *Shakspeare.*

Kings must be answerable to God; but the *ministers* to kings, whose eyes, ears, and hands they are, must be answerable to God and man. *Bacon.*

For the *ministerial* officers in court there must be an eye upon them. *Bacon's Advice to Villiers.*

The faithful *minister* provideth not only wholesome but plentiful food for his people. *Fuller.*

They that will have their chamber filled with a good scent, make some odoriferous water be blown about it by their servants' mouths that are dexterous in that *ministery*. *Digby.*

God made him the instrument of his providence to me, as he hath made his own land to him, with this difference, that God, by his *ministration* to me, intends to do him a favor. *Taylor.*

A *ministerial* headship or the prime *minister* cannot in any capacity become the foundation of the church to any such purpose. *Jer. Taylor.*

At table Eve
Ministered naked, and their flowing cups
With pleasant liquors crowned. *Milton.*

This temple to frequent
With *ministeries* due, and solemn rites. *Id.*

Him thrones, and powers,
Princedoms, and dominations *ministrant*,
Accompanied to heaven-gate. *Id. Paradise Lost.*

Their *ministry* performed, and race well run,
Their doctrine and their story written left,
They die. *Id.*

Though sometimes effected by the immediate fiat of the divine will, yet I think they are most ordinarily done by the *ministration* of angels. *Hale's Origin of Mankind.*

Unto him it *ministereth* a free address upon all occasions, with him it alloweth us continually a most sweet and pleasant intercourse. *Barrow.*

Understanding is in a man; courage and vivacity in the lion's service, and *ministerial* officiousness in the ox. *Browne.*

The wounded patient bears
The artist's hand, that *ministers* the cure. *Otway.*

The infernal *minister* advanced,
Seized the due victim. *Dryden.*

He safe from loud alarms,
Abhorred the wicked *ministry* of arms. *Id.*

There is no truth which a man may more evidently make out than the existence of a God; yet he that shall content himself with things as they *minister* to our pleasures and passions, and not make enquiry a little farther into their causes and ends, may live long without any notion of such a being. *Locke.*

Saint Paul was miraculously called to the *ministry* of the gospel, and had the whole doctrine of the gospel from God by immediate revelation; and was appointed the apostle of the Gentiles for propagating it in the heathen world. *Id.*

So far is an indistinction of all persons, and, by consequence, an anarchy of all things, from being agreeable to the will of God declared in his great household, the world, and especially in all the *ministries* of his proper household the church, that there was never yet any time, I believe, since it was a number, when some of its members were not more sacred than others. *Sprat's Sermons.*

He who has a soul wholly void of gratitude, should set his soul to learn of his body; for all the parts of that *minister* to one another. *South.*

To all but thee in fits he seemed to go,
And 'twas my *ministry* to deal the blow. *Parnel.*

The *ministers* are always preaching, and the governors putting forth edicts against dancing and gaming. *Addison.*

Fasting is not absolutely good, but relatively, and as it *ministers* to other virtues. *Smalridge's Sermons.*

From essences unseen, celestial names,
Enlightening spirits, and *ministerial* flames,
Lift we our reason to that sovereign cause,
Who blessed the whole with life. *Prior.*

Abstinence, the apostle determines, is of no other real value in religion, than as a *ministerial* cause of moral effects as it recalls us from the world, and gives a serious turn to our thoughts. *Rogers.*

The *ministers* of the gospel are especially required to shine as lights in the world, because the distinction of their station renders their conduct more observable; and the presumption of their knowledge, and the dignity of their office, give a peculiar force and authority to their example. *Id.*

Those good men, who take such pleasure in re-

lieving the miserable for Christ's sake, would not have been less forward to *minister* unto Christ himself.
Atterbury.

If the present *ministration* be more glorious than the former, the *minister* is more holy. *Id.*

Other spirits governed by the will,
Shoot through their tracks, and distant muscles fill;
This sovereign, by his arbitrary nod,
Restrains or sends his *ministers* abroad. *Blackmore.*

Supremacy of office, by mutual agreement, and voluntary œconomy, belongs to the father; while the son, out of voluntary condescension, submits to act *ministerially*, or in capacity of mediator.
Waterland.

The poets introduced the *ministry* of the gods, and taught the separate existence of human souls.
Bentley.

Ministrant to their queen with busy care,
Four faithful handmaids the soft rites prepare.
Pope.

I converse in full freedom with many considerable men of both parties; and if not in equal number, it is purely accidental, as happening to have made acquaintance at court more under one *ministry* than another. *Swift.*

Calidus contents himself with thinking that he never was a friend to hereticks and infidels; that he has always been civil to the *minister* of his parish, and very often given something to the charity-schools.
Law.

The profession of a clergyman is an holy profession, because it is a *ministration* in holy things, an attendance at the altar. *Id.*

Yet if I could collect my faultering breath,
Well were I meet for such sad *ministry*,
For grief hath left my voice no other sound.
Maturin.

A MINISTER, in the presbyterian ecclesiastical polity, is a clergyman, who preaches, performs religious worship in public, administers the sacraments, &c.

MINISTER, FOREIGN, is a person sent into a foreign country, to manage the affairs of his province, or of the state to which he belongs. Of these there are two kinds: those of the first rank are ambassadors and envoys extraordinary, who represent the persons of their sovereigns; the ministers of the second rank are the ordinary residents.

MINIUM, or red lead, is an oxide of lead of a vivid red color, which it acquires by a slow calcination and reverberation. See CHEMISTRY, Index. The minium in commerce is chiefly brought from Holland, where large quantities of it are manufactured. The method in which minium is made in large quantities with us is this: they first burn lead in a furnace into a kind of litharge, by continually stirring it while melted with an iron rake; this they afterwards grind with two pairs of stones, which deliver it from one to another; the first pair grinding it coarser, the second finer; these are worked by means of a mill, which moves six pairs of them at once. When thus reduced to a fine powder, it is washed and then put into a furnace, and is burnt with a reverberatory fire for two or three days; all the while they continue stirring it with a large iron rake, hung on a swivel or iron hook; and toward the end of the time they watch its color. When this is doing, the fire must not be carried beyond a certain degree, lest the matter clot and run together. The furnace is of the reverberatory kind, with two fire-places at the ends; each fire-place being separated from the area, or body of the furnace, by a wall twelve inches high. The fire-places are fifteen inches broad, and their length is equal to the breadth of the whole furnace, which is about eight or nine feet. The length of the area, from one place to the other, is nine or ten feet. The quantity of lead used in one operation is about 1500 lbs., of which nine parts are lead obtained from furnaces where the ore is smelted, and one part is lead extracted from the scoria which is formed in smelting the ore. This latter kind is said to be necessary, as the former could not alone be reduced into powder. All the lead is at once put into the area, the bottom of which is level. The calx, as fast as it is formed, is drawn to one side, by a rake suspended by a chain before the mouth of the furnace. In four or five hours the whole quantity of the lead is calcined, or, if any pieces remain uncalcined, they are separated, and kept for the next operation. The heat employed is that of a cherry red; and the fire-places and mouth are kept open that the air may accelerate the calcination. The calx is to be frequently stirred to prevent its concreting; and, when this operation has been continued about twenty-four hours, the matter is taken out of the furnace, and laid on a flat pavement. Then cold water is thrown on it, to give it weight, as the workmen say; but rather, as Mr. Jars thinks, to make it friable. It is then to be ground in a mill, and the finer part is separated by washing, while the coarser part, reserved for some following operation, is to be placed at the mouth of the furnace in order to retain the melted lead. The fine powder, which is now of a yellow color, is again put into the same or a similar furnace, and exposed to a very moderate fire, from thirty-six to forty-eight hours; during which time it is stirred frequently to prevent its concreting; and the powder gradually acquires its proper red color. The minium is then to be taken out of the furnace, cooled, and sifted through an iron sieve placed in a cask. The bright color of minium might render it valuable in painting, if it could stand with certainty in either oil or water. But, as it is subject to become black, it cannot be safely trusted, except in hard varnishes; and is, therefore, seldom used in oil, or even in water, unless for very gross purposes, or as a ground for vermilion. The goodness of minium may be distinguished by the brightness of its color; and the adulteration to which it is liable may be detected by putting an ounce of it into a crucible with an equal quantity of charcoal dust, well mixed together, and placing the crucible in a common fire sufficient to melt lead, which is to be covered with another small crucible inverted into it. When it has been continued for some time on the fire, take it out and strike it against the ground. The minium will thus be reduced to its metallic state; and its diminished weight, when freed from the charcoal dust, &c., will indicate the proportion of adulterated matter. Minium is also used as a flux in forming the enamel for grounds, and in glazing, &c. It is now called red oxide.

MINNIN, a stringed instrument of music among the ancient Hebrews, having three or four chords to it. There is reason to question the antiquity of this instrument; both because it requires a hair-bow, which was a kind of plectrum not known to the ancients, and because it so much resembles the modern viol. Kircher took the figures of this, the machul, chinor, and psaltery, from an old work in the Vatican library.

MIN'NOCK, *n. s.* Sax. man or mȳn and oᵹ: Goth. *ug*, a boy. An elf or mischievous urchin: It is not unlikely, as Dr. Johnson says, that minnock and minx were originally the same word.

MI'NNOW, *n. s.* Fr. *menue*; Span. *mena*, of Lat. *minus*. A very small fish.

MINK (*mustela*). The animal known in the United States under the name of *mink* is so similar to the European quadruped of the same name that they have been generally confounded with each other. The common name of both species is derived from the Swedish *menk*. The American animal is the *M. vison* of naturalists, and is generally to be found on the banks of streams, especially near farm-houses and mills. It swims and dives well, and can remain under water for a considerable time. It preys upon small fish, muscles, &c., but also commits depredations on the poultry yard, and will devour rats, mice, &c. The mink, when irritated, exhales a very fetid smell, almost equal to that of the skunk. It is easily tamed, and is capable of strong attachment, but, like the cat kind, is readily offended, and will bite on a sudden provocation. The fur is of little value.—The European mink (*M. lutreola*) inhabits the northern parts of Europe, and, like the American species, lives on the banks of streams, feeding on frogs, craw-fish, &c. It is of a brownish-red color. It has a strong musky smell, and its fur is very fine.

The MINNOW is a species of Cyprinus.

MI'NOR, *adj.* & *n. s.*
MI'NORATE, *v. a.*
MINORA'TION, *n. s.*
MINOR'ITY.
} Lat. *minor*; Fr. *minorité*; Ital. *minorita*; Span. *minoridad*. Little, petty; inconsiderable; less: a person under age; a legal infant; the second or inferior proposition of a syllogism: to minorate, is to make less or diminish: minoration, the act of lessening. (Both this verb and noun are of questionable authority.) Minority, the state of being less; the smaller number; state of being under age.

I moved the king, my master, to speak in the behalf of my daughter, in the *minority* of them both. *Shakspeare.*

The second or *minor* proposition was, that this kingdom hath cause of just fear of overthrow from Spain. *Bacon.*

Henry the Eighth, doubting he might die in the *minority* of his son, procured an act to pass, that no statute made during the *minority* of the king should bind him or his successors, except it were confirmed by the king at his full age. But the first act that passed in king Edward the Sixth's time was a repeal of that former act; at which time nevertheless the king was *minor*. *Id.*

King Richard the Second, the first ten years of his reign, was a *minor*. *Davies on Ireland.*

These changes in religion should be staid, until the king were of years to govern by himself: this the people apprehending worse than it was, a question was raised, whether, during the king's *minority*, such alterations might be made or no. *Hayward.*

It is the affection of too early ripeness that makes them prodigal of their children's safety and hopes; for, that they may be wise betimes, they send them forth to the world in the *minority* both of age and judgment. *Bp. Hall.*

They altered this custom from cases of high concernment to the most trivial debates, the *minor* part ordinarily entering their protest. *Clarendon.*

This it doth, not only by the advantageous assistance of a tube, but by showing in what degrees distance *minorates* the object. *Glanville.*

If there are petty errours and *minor* lapses, not considerably injurious unto faith, yet it is not safe to contemn inferior falsities. *Browne.*

We hope the mercies of God will consider our degenerated integrity unto some *minoration* of our offences. *Id.*

From this narrow time of gestation may ensue a *minority*, or smallness in the exclusion. *Id.*

Their counsels are warlike and ambitious, though something tempered by the *minority* of their king. *Temple.*

If there be evidence that it is not many ages since nature was in her *minority*, this may be taken for a good proof that she is not eternal. *Burnet's Theory of the Earth.*

Though we seem grieved at the shortness of life in general, we are wishing every period of it at an end. The *minor* longs to be at age, then to be a man of business, then to make up an estate, then to arrive at honors, then to retire. *Addison.*

A *minor* or infant cannot be said to be contumacious, because he cannot appear as a defendant in court, but by his guardian. *Ayliffe's Parergon.*

He and his muse might be *minors* but the libertines are full grown. *Collier's View of the Stage.*

He supposed that a philosopher's brain was like a forest, where ideas are ranged like animals of several kinds; that the major is the male, the *minor* the female, which copulate by the middle term, and engender the conclusion. *Arbuthnot.*

Long as the years dull circle seems to run,
When the brisk *minor* pants for twenty-one.
Pope.

The noblest blood of England having been shed in the grand rebellion, many great families became extinct, or supported only by *minors*. *Swift.*

MINOR, in law, denotes a person under age; or who, by the laws of the country, is not arrived at the power of administering his own affairs, or the possession of his estate. Among us, a person is a minor till the age of twenty-one; before which time his acts are invalid. See AGE, INFANT. It is a maxim in the common law that in the king there is no minority, and therefore he hath no legal guardian; and his royal grants and assents to acts of parliament are good, though he has not, in his natural capacity, attained the legal age of twenty-one. It is also provided, by the custom and law of parliament, that no one shall sit or vote in either house, unless he be twenty-one years of age. This is expressly declared by stat. 7 and 8 Will. III cap. 25, with regard to the house of commons.

MINOR, in logic, is the second proposition of a formal or regular syllogism, called also the assumption.

MINORS, in music, is applied to certain con-

cords, which differ from or are lower than others of the same denomination, by a less semitone or four commas. Thus we say, a third minor or less third, or a sixth major and minor. Concords that admit of major and minor, i. e. greater and less, are said to be imperfect concords. See MAJOR.

MINORS, FRIARS, MINOR, or MINORITES, appellations which the Franciscans assume. See FRANCISCANS. There is also an order of Regular Minors at Naples, which was established in 1588, and confirmed by Sixtus V.

MINORCA, the second of the Baleares islands, belonging to Spain, is forty miles long, north-west and south-east, and twelve broad, containing 800 square miles. The channel between it and Majorca, in the narrowest part between Capes Pera and d'Artush, is thirty miles. Minorca was taken by the English in 1708, and confirmed to them by the treaty of Utrecht, 1713. In 1756 it was retaken by the Spaniards and French, and admiral Byng fell a victim to the exasperation of the public mind, and to the safety of ministers, for not relieving it, with a force greatly inferior to that of the enemy.

In general this island is level, having but one hill of any elevation, named mount Toro, nearly in the centre of the island. The climate is less mild and temperate than that of Majorca, wanting the shelter which this latter receives from the mountains of Catalonia, against the violent northerly winds from the Gulf of Lyons, the effects of which are strikingly visible in the naked barrenness of the north coast, whose few trees are stunted and bent to the south. The want of elevations to arrest the clouds renders the summers hot and dry, while the autumns are wet, and the winter raw, though there is seldom snow or ice: the spring is therefore the only agreeable season, being pure and serene. The variations of the thermometer are between 48° and 80°. In general this island presents a base of calcareous rock, covered with a layer of earth and sand, and possessed of different degrees of fertility, according to the depth of this soil, or the preponderance of these substances. The island furnishes limestone, marbles, slate, potter's clay, and talc or muscovy glass. Iron ore is also met with, and it has some poor veins of lead. On the east coast are several lagoons, separated from the sea by narrow strips of land, through which the sea-water filters. They abound with excellent millet. In Levant winds their level is higher than the sea, and with westerly winds lower; the waters of the lake not following with equal celerity the irregular movements of the sea caused by these winds.

The only timber trees are pines and ever-green oaks. The crops of wheat, rye, barley, and Indian corn, taken together, are insufficient for the consumption. The wild quadrupeds are, a very few hares, abundance of rabbits, and some porcupines; the land tortoise is also met with. The domestic animals were, in 1805, 600 horses, asses and mules, 6000 to 7000 horned cattle, 40,000 to 45,000 sheep and goats, and 10,000 hogs. The larger cattle are similar to those of Majorca; the sheep and goats small and lean. The hogs, which are large, are in the autumn turned into the woods to feed on the acorns; and in winter are fed with barley, which renders their flesh excellent: and pork is the chief animal food of the Minorcans as well as Majorcans. The reptiles met with on the island are snakes and lizards; scorpions and centipedes are common. The birds taken for food are the red-legged partridge, quail, wild pigeons, doves, thrushes, woodcocks, snipes, wild duck, and teal.

The population of the island is about 30,000. In 1805 its military establishment consisted of 1500 chasseurs, 3100 infantry of the line, ninety cavalry, and 500 artillery: total 5,190 regulars; of whom 350 form the garrison of Ciudella, fifty of Fornels, and the remainder (with the exception of some small detachments of four to eight men, in the small forts and towers on the coast), are stationed at Port Mahon, where is also a park of field artillery. The governor is usually a brigadier in the armies of Spain. The inhabitants retain the partiality of their ancestors to the use of the sling; but they are a simple inoffensive race, who give themselves very little concern about the rest of the world, provided their course of life is not interrupted. They are not, however, incapable of activity; and, when the island belonged to Great Britain, they carried on a tolerably active shipping trade in the Mediterranean. They are very fond of processions, and of dancing to the sound of their rude musical instruments. Their dress and language are similar to those of Majorca.

The principal capes of the island are, Cape de Sella, the north point. Cape Mola, north of the entrance of Port Mahon, is a lofty peninsular promontory, descending perpendicularly to the sea; on it is a signal tower, and at its foot are three steep rocks. Cape d'Artush, the south-west point of the island, is low, with eighteen to twenty fathoms close to it, and E.S.E. of it a shoal, on which the sea only breaks in bad weather, with a passage within it for small craft only. Cape Bayoli is the west point of the island.

Port Mahon, the principal place of the island, is on the east coast, and one of the best harbours of the Mediterranean, being five miles deep; its greatest breadth one mile, and at its entrance only ninety fathoms. In the port are four islands; the first, called King's or Bloody Island, has on it a large building, erected for the naval hospital by the English in 1773: it was intended to hold 250 patients. On the second island are magazines and lodgings for receiving the cargoes and passengers of vessels arriving from the Levant, with clean bills of health, while performing quarantine. The name of the third, Lazaretto Island, denotes its uses; it is joined to the main land by a narrow neck, covered at high water. Redonda, the fourth island, is a circular mass of rock communicating with the main by a wooden bridge. On it were the English naval magazines and dwellings of the officers of the naval department, surrounded by a wall flanked with square towers; a pier runs out from it, at the extremity of which are masting shears, and alongside of which the largest ships heave down.

Opposite Lazaretto Island, on the south shore of the port, is the village of San Carlos, entirely

inhabited by sea-faring persons; here are also barracks for 4000 men. Midway, between this village and the city of Mahon, was the famous fort St. Philip, or the Ravalle, a league in circuit, which commanded the entrance of the port; but the works of which have been entirely blown up by the Spaniards, so that, at present, the only defences are a battery on the south shore, of twenty-three guns, eighteen and twenty-four pounders; Fort Philipet on the opposite shore, in which are but four or five guns; and a Martello tower, with but a single gun on the same shore. On one of the heights that line the north shore is a tower, which repeats to Mahon the signals from Mount Toro; which latter commands a view of the sea all round the island.

The city of Mahon is on the south shore, near the head of the port; it is built on elevated rocky ground, whence it enjoys the two advantages of a fine view and salubrity. The streets, which in general are narrow and crooked, are paved with large pebbles; the houses tolerably built of stone, with windows and chimney-places in the English manner, and each has a cistern to preserve the rain water. The principal public buildings are the government house, town house, a church, two convents of men, one of women, and a civil hospital. The town was formerly surrounded by a wall, of which the vestiges of one gate alone remain.

Commencing at port Mahon, and tracing the circuit of the island by the north, we meet in succession with the isle Coloms, tolerably high, with only a passage for boats within it. On its west is the road of Sessilanes, fit for vessels of middling size, sheltered from all winds but north-west, which throws in a great sea; but with good cables there is little danger. There is also a road on the south-east of the island, sheltered from all winds but E. N. E. to E. S. E., and a little haven for small craft entirely land-locked.

Port Adaye has depth only for small craft; off it are three islands, one of which is elevated and the two others very low. Port Fornels is an extensive basin, with a narrow entrance; but in which is seventeen to twenty fathoms, and no danger but what is apparent. Its entrance is defended by a little square fort, within which are barracks for 100 men, and by a tower on the opposite shore with an eighteen pounder. At the head of the port the English constructed a wooden fort of two stages, the lower serving for the lodgment of the soldiers, and in the upper one are port holes for four large guns. All these works are neglected by the Spaniards, who have here only fifteen soldiers. On the right shore of the port is a little hamlet of fishermen, its only inhabitants.

The gulf of Anfros is a large bay with high shores and several coves. Port Sanitge, half a mile deep, and one and a half cable's length broad at the entrance, can receive small vessels, which lie sheltered from all winds, opposite a cavern on the west shore. On the north-west of the port is the island Porcos, elevated on the north and very low on the south; the channel within it is only fit for small craft. The rock of Antichrist is a high head-land west of Port Sanitge.

Ciuda-della, or Cittadella, the capital of the island, is on the west end, south of Cape Bayoli; it is surrounded by a wall with bastions, and has barracks for 600 infantry and thirty horse; a cathedral, two parish churches, and four convents; with four cisterns of hewn stone to preserve the rain water. The streets are narrow, crooked, and badly paved. Its port is by no means good; for, though the entrance is narrow, west and south winds make a great swell in it: it terminates in marshy shoals. On the right side of the entrance is a Martello tower with two guns; and near it the church of St. Nicholas, held in great veneration by the Minorcan seamen. On the opposite shore is another tower. Saint Andros Cove, north of Cape d'Artush, is only fit for small craft. Saint Galdan's Cove, two miles east of the same cape, is the best road on the south coast, having shelter from all winds but west in four fathoms.

The Layre de Mahon is a small barren rocky island off the south-east point of Minorca, very low on the north-west, and rises to the south-east, where it terminates perpendicularly; in the channel within it is seven fathoms. A little salt is made on it.

MINOS I., in fabulous history, king of Crete, son of Jupiter and Europa. He flourished about A.A.C. 1432. He gave laws to his subjects, which remained in force in the age of the philosopher Plato, about 1000 years after his death. His justice and moderation procured him the titles of the favorite of the gods, the confident of Jupiter, and the wise legislator, in every city of Greece; and, according to the poets, he was rewarded for his equity after death with the office of supreme judge in the infernal regions. In this character he is represented sitting in the shades and holding a sceptre in his hand. The dead plead their causes before him; and the impartial judge shakes the fatal urn, which is filled with the destinies of mankind. He married Ithona, by whom he had Lycastes, the father of Minos II.

MINOS II., the grand-son of Minos I., and king of Crete, married Pasiphae, the daughter of Apollo and Perseis, by whom he had many children. He increased his dominions by the conquest of the neighbouring islands. He took Megara by the treachery of Scylla; and obliged the Athenians to send annually to Crete seven chosen boys and seven virgins to be devoured by the Minotaur. This bloody tribute was abolished when Theseus destroyed the monster. When Dædalus, whose industry and invention had fabricated the labyrinth, and whose imprudence in assisting Pasiphae in the gratification of her desires had offended Minos, fled with artificial wings from the place of his confinement, and arrived safe in Sicily, Minos pursued him, resolved to punish his infidelity. Cocalus, king of Sicily, who had hospitably received Dædalus, entertained his royal guest with dissembled friendship: and, to preserve an artist whose ingenuity and abilities he so well knew, he put Minos to death, about thirty-five years before the Trojan war. He was father of Androgeus,

Glaucus, Deucalion, Phædra, and Ariadne. Many authors have confounded the two Minoses; but Homer, Plutarch, and Diodorus, prove plainly that they were two different persons.

MI'NOTAUR, *n. s.* Fr. *minotaure*; Lat. *minos* and *taurus*. A monster of the poets, half man and half bull; said to be kept in Dædalus's labyrinth.

> Thou may'st not wander in that labyrinth,
> There *minotaurs*, and ugly treasons lurk.
> *Shakspeare.*

The MINOTAUR, in fabulous history, was the fruit of Pasiphae's amour with a bull. Minos having refused to sacrifice a white bull to Neptune, which he had received from the god for that purpose, Neptune, in revenge, made Pasiphae, the wife of Minos, enamoured of this fine bull. Dædalus prostituted his talents subservient to the queen's unnatural desires; and by his means Pasiphae's passions were gratified, and the Minotaur came into the world. Minos confined in the labyrinth this monster, where he devoured the young men and maidens annually exacted from the Athenians. Theseus delivered his country from this barbarous tribute, when it had fallen to his lot to be devoured; and by means of Ariadne, the daughter of Minos, destroyed the monster, and escaped from the windings of the labyrinth. The fable of the Minotaur has been thus explained:—Pasiphae was enamoured of one of her husband's courtiers called Ταυρος, or Tauros (which in Greek, as well as Latin, signifies a bull); and Dædalus favored the passion of the queen, by allowing his house to become the retreat of the two lovers. Pasiphae brought forth twins, one of whom greatly resembled Minos, and the other Taurus; whence originated the name, and the fable of the Minotaur.

MINSK, or MINSKK, an important province of western European Russia, comprehending the old palatinate of Minsk, and portions of Polotzk, Novogrodek, and Wilna. Extending from the Dwina on the north to Volhynia south. Its area is about 37,000 square miles, containing 950,000 inhabitants. It is divided into ten circles. Minsk is little better than a dead flat, but productive wherever the soil is called into operation by culture; but a great part, particularly of the south, is overrun with marshes and forests. The rivers are numerous, and some of considerable size. The chief are the Dwina, Dnieper, Niemen, and Beresina; the last memorable for the struggle on its banks between the Russians and the French, in the retreat of the latter from Moscow, in 1812. All the productions of Lithuania are found here; but wood and potash are the chief articles of export. The inhabitants are Poles, Lithuanians, Tartars, Armenians, Greeks, Jews, and gypsies. The chief part are Catholics; but there is also a number of Protestants, and members of the Greek church.

MINSK, a town of Russian Lithuania, the capital of the government of this name, is situated on the Swislocz, and has an abbey of the Greek church. Population 2000, chiefly Jews. 310 miles E. N. E. of Warsaw.

MIN'STREL, *n. s.* } Span. *menestrel*; low
MIN'STRELSY. } Lat. *menestralus*. A musician; one who performs instrumental music: minstrelsy, the music or harmony resulting; also a number of musicians, taken collectively.

> I to the vulgar am become a jest;
> Esteemed as a *minstrel* at a feast.
> *Sandys's Paraph.*
>
> Hark how the *minstrels* 'gin to shrill aloud
> Their merry musick that resounds from far,
> The pipe, the tabor, and the trembling croud,
> That well agree withouten breach or jar.
> *Spenser.*
>
> I will give you the *minstrel*.
> —Then I will give you the serving creature.
> *Shakspeare*
>
> Apollo's self will envy at his play,
> And all the world applaud his *minstrelsy*.
> *Davies*
>
> That loving wretch that swears,
> 'Tis not the bodies marry but the minds,
> Which he in her angelick finds,
> Would swear as justly, that he hears,
> In that day's rude hoarse *minstrelsey*, the spheres
> *Donne.*

The Israelitish dames, when they saw their danger, though they might have left their timbrels behind them; yet now they live to renew that forgotten *minstrelsey* and dancing. *Bp. Hall.*

> I began,
> Wrapt in a pleasing fit of melancholy,
> To meditate my rural *minstrelsey*,
> Till fancy had her fill. *Milton.*
>
> These fellows
> Were once the *minstrels* of a country show;
> Followed the prizes through each paltry town,
> By trumpet cheeks and bloated faces known.
> *Dryden.*
>
> Often our seers and poets have confessed,
> That musick's force can tame the furious beast;
> Can make the wolf, or foaming bear restrain
> His rage; the lion drop his crested mane,
> Attentive to the song; the lynx forget
> His wrath to man, and lick the *minstrel's* feet.
> *Prior.*

MINSTREL is by others derived from the French menestrier, and was not used in England before the Norman conquest. They united the powers of melody, poem, and dance. The Saxons, as well as the ancient Danes, had been accustomed to hold men of this profession in the highest reverence. Their skill was considered as something divine, their persons were deemed sacred, their attendance was solicited by kings, and they were every where loaded with honors and rewards. In short, poets and their art were held among them in that rude admiration, which is shown by an ignorant people to such as excel them in intellectual accomplishments. When the Saxons were converted to Christianity, in proportion as letters prevailed among them, this rude admiration began to abate, and poetry was no longer a peculiar profession. The poet and the minstrel became two persons. Poetry was cultivated by men of letters indiscriminately; and many of the most popular rhymes were composed amidst the leisure and retirement of monasteries. But the minstrels continued a distinct order of men, and obtained their livelihood by singing verses to the harp at the houses of the great. There they were still hospitably and respectfully received, and retained many of the honors shown to their predecessors, the bards and scalds. And, indeed, though some of them only recited the compositions of others, many of

them still composed songs themselves; and all of them could probably form a few stanzas on occasion. In the fourth year of Richard II. John of Gaunt erected at Tetbury, in Staffordshire, a court of minstrels, with a full power to receive suit and service from the men of his profession within five neighbouring counties, to enact laws, and determine their controversies; and to apprehend and arrest such of them as should refuse to appear at the said court, annually held on the 16th of August. For this they had a charter, by which they were empowered to appoint a king of the minstrels, with four officers to preside over them. These were every year elected with great ceremony; the whole form of which is described by Dr. Plott; in whose time, however, they seem to have become mere musicians. Even so late as the reign of king Henry VIII. the reciters of verses or moral speeches intruded, without ceremony, into all companies; not only in taverns, but in the houses of the nobility. We find that the minstrels continued down to the reign of queen Elizabeth; in whose time they had lost much of their dignity, and were sinking into neglect. One of them is thus described by a contemporary writer:—'About his neck a red ribband suitable to his girdle. His harp in good grace depending before him. His wrest tyed to a green lace and hanging by: under the gorget of his gown a fair flaggon chain, silver, as a squire minstrel of Middlesex, that travelled the country unto fair and worshipful men's houses. From his chain hung a scutcheon, with metal and color resplendent, upon his breast, of the ancient arms of Islington.' Towards the end of the sixteenth century this class of men had lost all credit, and were sunk so low in the public opinion, that, in the 39th of Elizabeth, a statute was passed by which 'minstrels, wandering abroad,' were included among 'rogues, vagabonds, and sturdy beggars,' and were adjudged to be punished as such. This act seems to have put an end to the profession.

MINT, *n. s.* Sax. minте; Fr. *menthe;* Lat. *mentha,*

Mint (*mentha*); a genus of labiate plants, distinguished, however, by having the corolla divided into four nearly equal lobes. The stamens are four, two of them longer than the others. The species are herbaceous, nearly all perennial, having square stems, which bear opposite and simple leaves; the flowers are small, verticillate, collected into bunches in the axils of the leaves. Sixty species are known, all growing in temperate climates, and most of them European. Two or three species only inhabit the United States. They abound in resinous dots, which contain an essential oil. They have an agreeable odor, and have been celebrated, from remote antiquity, both in mythology and from their useful qualities. They partake, in the highest degree, of the tonic and stimulating properties which are found in all labiate plants. The *Mentha piperita,* or pepper-mint, is the most powerful, and, on this account, is most generally employed in medicine. The *Mentha viridis,* or spear-mint, is milder, more agreeable, and is very commonly employed for culinary purposes.

Mint, *n. s.* & *v. a.*
Mint'age, *n. s.*
Mint'er,
Mint'man,
Mint'master.
Sax. mynetian; Belg. *munten;* Teut. *muntzen,* to coin. A place where money is coined; hence, (meta.) a place productive of inventions or conceits: as a verb, to mint is to coin or invent: mintage, coinage; also duty paid or allowance made for coining: a minter, is a coiner: mintman, one skilled in this art: mintmaster, one who presides over or directs it; also an inventor or discoverer.

A man in all the world's new fashion planted,
That hath a *mint* of phrases in his brain.
Shakspeare.

Sterling ought to be of pure silver called leaf silver, the *minter* must add other weight, if the silver be not pure. *Camden.*

That which is coined, as *mintmasters* confessed, is alloyed with about a twelfth part of copper. *Boyle.*

The great *mintmasters* of these terms, the schoolmen and metaphysicians, have wherewithal to content them. *Locke.*

What is a person's name or face, that receives all his reputation from the *mint,* and would never have been known had there not been medals.
Addison on Medals.

As the *mints* of calumny are at work, a great number of curious inventions are issued out, which grow current among the party. *Addison.*

When Scandal has new *minted* an old lie,
Or taxed invention for a fresh supply,
'Tis called a satire, and the world appears
Gathering round it with erected ears. *Cowper.*

An actor is in the capacity of a steward to every living muse, and of an executor to every departed one; the poet digs up the ore; he sifts it from the dross, refines and purifies it for the *mint:* the actor sets the stamp upon it, and makes it current in the world. *Cumberland.*

Mint. The mint, which now forms so real an ornament to the eastern side of Tower Hill, has derived its name from the important business of coining having been originally conducted within the Tower.

This attribute of sovereign power was exercised by our Anglo-Saxon monarchs. Mr. Turner (History of Anglo-Saxons, vol. II. 134) considers that the use of coined money came in with the Roman ecclesiastical power; but no gold coins of this period of our history have reached us: that metal our historian thinks was only used in an uncoined state. See the article Coins. Mints were established (Wilkins's Leg. Anglo-Saxons) at various considerable places beside the capital; indeed, from Domesday-book, they seem to have been a usual appendage of large towns.

Athelstan, according to Mr. Ruding, first enacted regulations for the government of the mints. In his laws, promulgated about the year 928, he provided that one sort of coin only should be current throughout the kingdom, and granted to certain towns, by name, a number of moneyers, proportionate to their size and consequence, and to all boroughs of inferior rank one moneyer each. These mints were under the general control of that within the tower of London, from which, as paramount, the dies were issued; and for which the moneyers paid a regular fee upon every alteration of the coins.

They also paid an annual rent, which, in the city of Lincoln, amounted to £75 (according to the statement of Doomsday-book), a very considerable sum at that time. The rents of the other mints were, however, much smaller.

As well as these, the author of Annals of the Coinage notices certain early mints not directly subordinate to the crown, and founded either upon usurpation or upon grants of the sovereign to individuals or corporate bodies. Of these several are mentioned as in the hands of the barons in the reign of Stephen. Athelstan confined the ecclesiastical mint to Canterbury, where the archbishop was allowed two moneyers, and the abbot one; and to Rochester, where the bishop was authorised to employ a single moneyer: but in these and all succeeding grants from the crown, while the profits of the coinage effected was assigned to the church, the dignitaries in question were forbid to use any dies but what they received from the tower of London, and for the use of which they were compelled to pay a rent to the master of the mint. In later times, however, certain ecclesiastics were permitted to add distinguishing signs, or mint marks to their money, or, at least, on the smaller coins; for it was one of the articles of impeachment against Wolsey, that he inserted a cardinal's hat on the larger ones.

Connected with the various provincial mints were exchanges, established in certain large towns for the purpose of receiving in the old, and distributing new coins. Here also bullion and plate were purchased in the name of the sovereign; foreign coin exchanged for that of the kingdom, or supplied to travellers and merchants, according to public tables of their value.

The series of coins from the metropolitan and other ecclesiastical mints terminates in the reign of Henry VIII., Cranmer and Lee, the archbishops of Canterbury and York of that period, being the last who exercised this privilege: but it was not until the reign of queen Mary that the subordinate royal mints were finally abolished. The coinage has ever since been exclusively conducted at the tower, with the exception of a short period in the reign of Charles I.; another in that of his son; and during the great recoinage immediately after the Revolution, when mints were once more put in operation in York, Chester, Exeter, Bristol, and Norwich. To these exceptions the annalist finally adds the new 'era' which 'started up' in the late reign, i. e. in the mint for the copper coinage, conducted by Mr. Boulton at Soho.

In 1806, the other uses to which the tower buildings had become devoted having rendered the part appropriated to the mint within the tower very inadequate for the purpose, a portion of what was called the Little Tower Hill (formerly occupied as the government tobacco warehouse) was selected as the site of a new mint. Grants of money were made by parliament from this time to 1810, amounting in the whole to £261,977 for the erection of the present elegant and commodious structure, with its machinery; and in no part of the world besides, we believe, are equally effective and scientific coinage operations now carried on.

The head officer of this establishment is the *master of the mint*, an appointment of sufficient influence and emolument to be considered technically ministerial; and it generally therefore follows the usual changes of administration. To Mr. Wellesley Pole, who held it during the ministry of lord Liverpool, the mint is indebted for its existing and completely renovated constitution, founded on a report of that gentleman to a committee of the privy council; and which took effect in the year 1815. According to this the practical duties of the mint are thus regulated:—

1. The *deputy-master, and worker*, is to receive, on account of the master and worker, his majesty's own bullion of gold and silver, as well as the bullion of any other person, brought to the mint for coinage: to give acknowledgments for the same, specifying the number of ingots, or parcels of coin, according to the purport of any invoice or bill delivered therewith: to see the ingots safely deposited in the care and joint custody of himself and the master's assayer, for the purpose of being assayed previous to their importation into the office of receipt: to cause ingots, when duly assayed, to be brought into the office of receipt without delay, there to be weighed in the presence of the importers and check-officers: to make out a mint bill, to be delivered to the importer, testifying the weight, fineness, and value of the several ingots, &c., together with the day and order of the delivery into the mint, and to sign a receipt annexed to the said bill, witnessed by the comptroller and king's clerk: to give directions to the master's first clerk, for the combining or potting the ingots for the melting, with the proper portion of alloy; and to see that the same be duly entered by the said first clerk and melter, in the pot-book, and the said book examined by the comptroller and king's clerk; and to deliver out of the strong hold such ingots and bullion as are potted, and charge the melter therewith, according to the standard weight of each pot: to keep an account of the bars received from the melting-house, and delivered to the moneyers, and also of the scissell returned by the moneyers to the melter, for which their respective receipts will be given and entered in the pot-book, that they may be charged therewith: to receive the coined monies from the moneyers, after the same have been duly tried at the pix by the king's assayer, comptroller, and king's clerk; and to deliver the same to the importer, receiving back at the same time the mint bill which had been given; or, if the same be not cleared off, to require that such portion thereof as has been delivered, be indorsed on the bill by the parties, by a receipt, till the whole be discharged: to seal and lock up in the usual chest, in conjunction with the king's assayer and comptroller, the pieces reserved for the public trial of the pix, and to make good to the parties the pieces so taken, by payment in their sterling value; charging the same to the public expense.

As first executive officer of the mint, to watch over every branch of the department, and to inspect and oversee, as much as lies in his power, the meltings, assayings, and all the different processes of the coinage, and to report to the master

on the conduct of the officers: to draw and indite all letters, instructions, commissions, and other writings agreed upon and ordered by the master and worker, for the service of the office, and to have the same recorded by the clerk of the papers: to receive all monies issued at the exchequer or elsewhere, for the service of the mint; and to keep the public account of the master, to be laid annually before the auditors of public accounts, with the proper vouchers, the said account to be signed and attested by the master himself: to make quarter books of the salaries, wages, allowances, &c., due to the several officers, clerks, artificers, and others belonging to the establishment; and to make payment thereof on the quarter days, namely the 5th of January, the 5th of April, the 5th of July, and 10th of October, whenever there shall be funds for that purpose: also, to pay the moneyers' and melters' charges for coinage, according to the rates set forth in their respective agreements with the master; the same to be payable out of the monies issued for the service of the mint, the salaries &c., being previously discharged: also, to pay the incidental expenses and disbursements usually incurred in the different offices; and to pay the solicitor his account for disbursements in carrying on prosecutions for offences against the laws relating to the coin, out of such monies as shall be impressed from time to time, for that service, exclusive of the ordinary allowance: to receive all the fees arising to the master's office under the indenture or otherwise, and to apply the said fees to the payment of the master's salary, in the manner directed by the act 39th Geo. III., and to account for the same to the lords commissioners of his majesty's treasury, by half yearly statements, showing the deficiency of the fees, and the sum to be provided, or the excess, as may happen; and to make out a yearly account to the treasury.

For this office he is to give the usual security, or such other as may be required by the lords of the treasury: in conjunction with the comptroller, to inspect and examine the accounts of the clerk of the irons, as to the dies supplied to the engraver and moneyers, and the faulty ones destroyed; to attend the duties prescribed by the act 14th Geo. III. respecting the standard money weights.

2. The *king's assayer* is to keep a book of the assays made by him, of all such gold and silver as may be brought into the mint, whereby the quantity and fineness may appear. If the master of the mint, or the merchant, or importer, who brings his gold or silver for coinage, may not accord between them of the true value of the bullion, or if it be not malleable and fit for working, or sufficiently nigh to the standard, according to the customs of the mint, the king's assayer is to try the truth in that part, in the presence of the master and comptroller, and the master shall receive the same in manner as it becometh: to report (after the bullion has been weighed, potted, and melted) the assay of every several pot, commonly called the pot assay, which pot assay shall be made of some bar of the said bullion, to be taken by the comptroller, the king's assayer, or surveyor of meltings, or any one of them, after the pot is cast out; the said report to be made in writing, and delivered through the office to the surveyor of melting: to take care that the bars of gold and silver be melted, and the monies made agreeably in fineness to the indented trial plates, made by direction, and ordered to be used by the royal authority; whereof one trial plate for the gold, and one for the silver, shall remain with the king's assayer.

In conjunction with the other principal officers to oversee and survey the assaying, and melting, and making the monies, at all times and in all places: and endeavour and procure that the said monies, and every of them, shall be properly made and perfected: to see and procure, with the comptroller, and weigher, and teller, that the balances and weights be put to point from time to time, when they shall need it; so that no default be found in them, to the hurt of his majesty and his people: to make proof (by a process called the pixing) of the monies before their deliverance to the bringers in of the bullion; the said proof to be made in the presence of the master and worker, comptroller, and king's clerk, by an assay to be taken of the fineness as well as of the weight, by such quantity, and after such sort as shall be agreed on or as has been customary, namely, by weighing the pound weight in tale; and taking one piece out of every journey weight of gold and silver respectively for the assay of the fineness, as directed by the mint regulations. To report thereon, and the report to be entered in the pix books: in conjunction with the master, and worker, and comptroller, to see a portion, namely, one piece out of every journey weight of the said monies (after they have been proved to be good), ensealed in a packet, and put into a box (called the pix-box), to be locked up under the separate keys of the said officers, there to remain until trial thereof by jury (called the trial of the pix) shall be made before the king, or such of his council as are usually appointed at Westminster, or elsewhere for that purpose.

He shall be bound to instruct in the art of assaying, the probationer assayer, who shall be nominated by the king's assayer, and approved by the master and worker: to attend the duties prescribed by act 14th Geo. III. respecting the standard money-weights.

3. The *comptroller* is to enter on record, in a journal or ledger, all such bullion of gold and silver as shall, from time to time, be brought into the mint, which entry shall comprehend the weight as declared by the weigher and teller; the fineness as reported by the master's assayer; and the value of the said bullion, the parties' names that brought it, and what day: to deposit at the office of receipt in the strong-hold, of which he shall possess a key (in conjunction with the deputy-master and worker, and king's clerk), the bullion, after it shall have been received, and the assays and weight thereof made, reported, and entered, there to remain until it is required to be delivered by the deputy-master for the meltings: in conjunction with the king's clerk, to take an account of the ingots delivered by the deputy-master out of the strong-hold for the meltings, according to the entry made by the master's first clerk and melter in the pot-book

and to examine the said book as to the calculations of the quantities and fineness, of all manner of gold and silver and alloy, combined and put to each pot respectively for the meltings, and to subscribe the same with his initials: to take also an account and oversee the weighings of the bars and scissel, passed through the office between the melter and moneyers; for which their respective receipts shall be entered in the pot-book: to keep an account of all the deliveries of the monies; and to ascertain, at the end of every month or oftener, the balances due by the master to the several importers, and also the balances in the hands of the moneyers and melter, and agree the same with the deputy master, who is to charge the said moneyers and melter therewith accordingly: in conjunction with the other principal officers, to oversee the melting, rolling, sizing, and making, the monies, at all times and in all places; and endeavour and procure that the said monies and every of them shall be made and perfected: to see and procure, with the king's assayer, and weigher, and teller, that the balances and weights shall be put to point from time to time when they shall need it so that no default be found to the hurt of his majesty or his people.

To attend the proof and trial (called pixing) of the monies before their deliverance to the importer, and to try the weight of some of the pieces in each journey weight singly, as a check that there may be no great variation from the true weight; and also to retain two pieces from each journey weight, one to be delivered to the king's assayer for his assay, and the other to be locked in the pix-box, to be tried before the king or his council;—to docquet the parcel containing the pieces for the pix, and with the other officers enseal the same, and lock it in the pix-box: to deliver upon oath, before one of the barons of exchequer, a roll, which shall be called a comptroller's roll, containing an account of all the gold and silver monies coined monthly in the said mint: in conjunction with the deputy-master to inspect and examine the accounts of the clerk of the irons, as to the dies supplied to the engraver and moneyers, and that the faulty ones be destroyed: to attend the duties prescribed by act 14th Geo. III. respecting the standard money-weights.

4. The *superintendent of machinery and clerk of the irons* is to inspect, from time to time, the several steam-engines and boilers, and the machinery, apparatus, and implements, used in the coinage, and to see that the same are kept in proper order for immediate working at all times: to oversee and direct, in conjunction with the company of moneyers, the artificers and workmen employed by government about the machinery in doing all manner of work that may be expedient, and likewise in the construction of all the smaller implements and tools necessary to carry on the coinage, upon the principle of the machinery erected; the repairs and work being ordered under the authority of the master and board of mint officers: to superintend the working of the machinery, and instruct (to the best of his ability) the officers and moneyers in the use and management of it; and to report to the board upon any neglect or misuse: to examine the several accounts of expenses incurred in the machinery,—certifying, in pursuance of the agreements entered into between the master and the moneyers, the charges, both in respect to the bills, and also the wages to the artificers, which shall respectively be borne both by the government and the moneyers.

As *clerk of the irons*, to superintend the die press-rooms; and purchase, or procure to be forged, at the cheapest rate, to be approved by the board, all such dies as shall be ordered by the board, and to take care that the same are of the best quality and properly forged: to oversee the workmen in the die-press room, and that the dies be skilfully sunk and hardened, and properly turned; and to attend to all matters and things for the well ordering and conducting this service: to keep a true account of all the blank dies, matrices, and puncheons for coinage, which shall be delivered to the engravers, or that shall be sunk or stamped by the engravers, and after stamping made fit for use and hardened: to require the engravers, monthly, to return as many dies as shall be found faulty and worn: to give an account, as often as required, to the master and comptroller, of the blank dies delivered to the engravers, and the faulty ones returned, that a just account may be kept, and all the faulty dies defaced: to unlock and be present whenever the great die-press for multiplying the dies is used; to be responsible for its not being applied for improper purposes; and that no medals, pattern-pieces, or coin of any description be struck, but by a written order from the master or his deputy.

5. The *king's clerk, and clerk of the papers*, is to attend the weighings in, and enter in his ledger-book an account of all such bullion of gold and silver, as shall be brought into the mint, describing the weight and fineness as reported, the parties names that brought it, and the day: to deposit at the office of receipt in the strong-hold, of which he shall possess a key in conjunction with the deputy-master and comptroller, the bullion, after it shall have been weighed in, and the weight and assays reported; there to remain until it shall be required to be delivered over by the deputy-master for the meltings.

In conjunction with the comptroller, to take an account of the ingots delivered by the deputy-master to the melter, as set down in the pot-book, and to examine the calculations of the pot-book as to the quantities and fineness of all manner of gold, and silver, and alloy, put to each pot, and to subscribe the same with his initials: also to take an account and oversee the weighing of the bars and scissel passed through the office between the melter and moneyers, for which their respective receipts shall be entered in the pot-book: to attend the pix and deliverance of the monies, and record the same, and agree the master's, melter's, and moneyer's balances, up to the end of every month: to enter (as clerk of the papers) in the record-book, all office-letters, papers, appointments, warrants, and proceedings of the board: to assist the deputy-master in the secretary department, and instruct the master's

second clerk in the keeping the proper entries of bills and accounts for expenses incurred, or in making copies of all such papers as shall be required by the master or his deputy, or by the board.

6. The *master's assayer* is to receive from the master and worker all manner of gold and silver ingots brought to the mint: to deposit the same in the joint custody of the deputy-master and himself, in the strong-hold of the assay office, till the assays are made: to cut one or more pieces from each ingot (as he may think proper), and assay the same: to make written reports of the assay of each ingot, describing the fineness, date, and name or mark of the importer, and keep a record thereof. To make also such remarks on the quality of the bullion as may be needful for the master's information, and to deliver the list usually given by the importer of the purchase assays: to give instructions for the classing of certain of the ingots together, so that the bullion may be mixed and worked as close to the standard as possible, and advantages procured by the mint assay: to deliver the ingot when assayed into the office of receipt.

7. The *master's first clerk and melter* is to superintend and carry on the operations of the meltings and refinings, according to agreements (stating the prices and conditions) to be made from time to time between the master and melter: to attend the weighings in at the office, and rate and standard the ingots in conjunction with the other officers; and their several accounts agreeing to enter the same in his journal; so that no difference may arise between the deputy-master and himself as to the value of the bullion to be delivered to melt: to arrange under the direction of the deputy-master from the said journal, and from the list of ingots classed by the master's assayer, the combination of the bullion for melting, and to make the proper calculations of the quantities and fineness of all manner of gold and silver and alloy put to each respective pot, and to enter the same fairly in a book (called the pot-book), and subscribe his initials to each pot so made up: to receive the bullion so prepared from the deputy-master, to be deposited and melted under the joint custody and inspection of himself and the surveyor of meltings: to melt and cast the bars (according to agreement); and, after they have been assayed and reported standard by the king's assayer, to deliver them into the office of receipt; there to be weighed by the weigher and teller, in presence of a check officer, and passed to the moneyers: to receive the returns of scissel, light work, and ends (according to agreement), from the moneyers, to be weighed in like manner, the receipts between the moneyers and melter for the bar and scissel being entered in the pot-book: to receive from the deputy-master all such gold and silver as may be necessary to refine; to make up an account in the pot-book of each charge, showing the standard amount, to be signed with his initials, and examined by the comptroller and king's clerk; and to supply a quantity of fine ingots, equal in standard weight by computation to the amount delivered to refine, the same to be assayed by the master's assayer, and weighed into the office of receipt, and rated and standarded so as to combine and pot with the coarse ingots: to agree the balances remaining in his hands with the deputy-master at the end of each month: to employ and instruct the master's second clerk in the art of melting bullion; and, lastly, to be ready to do his work at all times, when he shall be warned by the master and worker; and to attend to his majesty's service as need shall require, both morning and afternoon, and to work so many hours every day (Sundays excepted) at such tasks as shall be thought fit by the master, and appointed by the board.

8. The *provost and company of moneyers* are to superintend and carry on jointly as a company, the several processes for the manufacture of the coin, in the rolling, annealing, blanching, cutting out, sizing, and stamping, according to agreements (specifying the prices and conditions) to be made from time to time, between the master and worker, and the provost and company: to receive the standard bars of gold and silver for making the monies, from the melter at the office of receipt, there to be weighed by the weigher and teller, in the presence of a check officer, and to give receipts for the same to be entered in the pot-book: to coin such quantities of the different species of the monies as shall be directed by the master (according to agreement), and to bring the said monies (in clean pieces) into the office of receipt, in journey weights; there to be tried at the pix and weighed: to deliver the monies proportionally in weight, according to the bars received; and, if any thing lack of the weight at the time of deliverance, to content and pay unto the master the balance at the time of the delivery: to make out of the bars which shall be delivered to them clean and fit to be wrought, seven-twelfth parts into money, so that there be but five parts in twelve scissel: to return the scissel, light work, and ends to be remelted, proportionally (according to agreement); the same to be delivered into the office of receipt, to be weighed by the weigher and teller, in the presence of a check officer, and to take receipts from the melter to be entered in the pot-book: to agree with the deputy-master the balance remaining in their hands at the end of each month, that they may be charged therewith; and from time to time (as the master shall require) make full payment and deliverance of all manner of monies, with all convenient speed, in order to discharge the said balances, or bring in sufficient supplies of gold and silver, bullion, or ingots, equal in value, according to the weight and assay to be made thereof at the time: not to take either singly by the provost, or jointly by the company, any apprentice to be instructed in the art or mystery of a moneyer, or any part thereof, without the license and permission of the master first had and obtained under his hand in writing.

To oversee, in conjunction with the superintendent of machinery, who is to direct the same, the artificers enployed by government about the machinery, in doing all manner of work that may be expedient, and in the construction of the smaller tools and implements for the coinage.

to be ready to do their work at all times without denial, when they shall be warned by the master: duly to attend his majesty's service, in the present way of coining, as need shall require, both morning and afternoon; and to work at such tasks, and so many hours every day (Sunday only excepted), as shall be thought fit by the master, and appointed by the board, according to the labor of their respective tasks, and the length of days: neither the provost, nor any of the moneyers, their apprentices or servants, at any time, to vend, pay, or distribute any piece or pieces of the coined monies, until the same shall have been delivered by them, according to the course of the mint, into the office of receipt, and duly assayed and pixed.

9. The *chief engraver* is to make and frame such draughts and embossments, or receive such models for engraving, as the master shall direct: to engrave from the said designs or models all such matrices and dies as the master shall direct, and the service of the mint require: to oversee from time to time the multiplication of the puncheons and dies, in the die press-room, and to receive the dies from the superintendent and clerk of the irons, that they may be delivered to the surveyor of the money presses in a proper state for the use of the coinage: to return monthly to the superintendent and clerk of the irons as many dies as shall from time to time be found faulty, and worn by using or otherwise.

Not to work, or make, or grave any puncheons, matrices, dies, or stamps, for the making or coining of any money, but only in such places in the mint as shall have been assigned thereunto: to oversee the striking of the monies in the coining press-room, and to direct all such dies as are faulty to be taken out of the press, and fresh dies put in, that the monies may be properly struck.

10. The *weigher and teller* is to weigh at the office of receipt, under the master's direction, all manner of bullion brought to the mint to be coined, or for the service of the king: to weigh the bullion, according to such weight or draught (near to a journey weight) as has been customary: all importations to be weighed in the presence of the deputy-master, or master's clerk, comptroller, or king's clerk, and the importer, who is to state the weight of each ingot from his list, for the guidance of the weigher: to declare the weight aloud from his scale, that the same may be taken down by the officers and importers: in conjunction with the other officers, to see that the bullion is free from dirt, and in a fit state for weighing, and to do strict justice, as much as in him lies, between the parties.

To weigh the bars and scissel, passed between the moneyers and melters, and declare the weight of each draught; and also all supplies of fine ingots received from the melter; and the balance or supplies of ingots, &c., made from time to time by the moneyers and melter: to weigh the coined monies from the moneyers to be delivered to the importers in even journey weights, or to declare the plus or minus on each draught, that the same may be recorded, and the moneyers made answerable for the deficiency of weight or balance at the time of deliverance: to attend the pix, and tell out the number of pieces contained in a pound weight Troy of the respective species of monies to be delivered to the king's assayer for trial: to undertake by himself, or by a proper workman in the mint (according to an agreement of prices and conditions), to clean and adjust the beams, &c., in the office of receipt, and to keep the same in order, so that they be always ready and perfect for working.

11. The *surveyor of meltings* is to survey the meltings of all gold and silver, and to take care that the ingots or bullion, according to the number and description in the pot-book, with their proper alloy only, to be weighed by himself, be put into the pot they are respectively set out for: to see that nothing but scissel or such returns or ends as be clean and good, of gold and silver, respectively, be put into the pots of scissell: during the time the pots are melting not to absent himself, or to be out of view of the pots so melting, until they have been poured off: to take two or more assay pieces from some bar or portion of each pot cast from the top, middle, or bottom, of the pot, as agreed with the king's assayer: to fold up each assay-piece in a paper, docqueted with a description of the ingots and alloy, or scissel, &c., melted in each pot, the number of the pot and the date, and to deliver the same to the king's assayer: to possess a key of the strong-holds in the melting house, and not to suffer any bars of gold or silver to be delivered out of his custody, until such time as they have been duly assayed and reported good, which reports will be made to him in written notices, transmitted through the office by the king's assayer: to keep a book containing the weight of all gold and silver as shall be molten from time to time, with the alloys put into the same.

12. The *surveyor of the money presses* is to inspect the coining presses, and to have a distinct and separate lock upon each of the presses: to be present at the striking of the monies, and not to suffer the presses to be used for striking any pieces or coins but such as the master shall direct: to have the custody of the dies received from the engraver and clerk of the irons, to give out the same for coinage, and return the faulty ones to the chief engraver, to be delivered to the clerk of the irons: to polish the dies, or oversee the doing of the same, when the moneyers are coining: to inspect the monies, that they be well made and free from brokages, and faulty or dirty pieces; and to do, execute, and perform, all such other works and services in the said office as the master shall direct and appoint.

13. The *probationer assayer* is to receive instructions from the king's assayer for acquiring a knowledge and proficiency in the art of assaying: to do all such services, in carrying on the business of the assay-office, as the king's assayer shall require and the master direct.

14. The *master's second clerk* is to make out fair copies and entries of all such accounts and papers as might be required in the master's office, and to do all such services in the said office as the master or deputy-master shall direct or appoint: to receive instructions from the

master's first clerk and melter in the art and undertaking of the meltings.

15. The *assistant engraver* is to assist the chief engraver in the engraving of the reverses, lettering, or such other parts of the dies as the chief engraver shall appoint: to receive instruction from the chief engraver in the art of engraving, and to render all such services in the department as the chief engraver shall require, and the master direct.

16. The *mint or bullion porter* is to attend the office daily, if required: to be present at all importations and deliveries at the office: to mark on the assay paper the weight of each ingot weighed at the scale: to arrange, with the assistance of the master's porter, the ingots in the strong-hold, and put them together in pots, to be carried down to the melting-house: to oversee the under porters in giving all proper assistance at all the weighings, and in the receipt into the mint of all bullion, and deliverance of monies or bullion: to give the regular notices for the attendance of the officers, and other persons at the office, for business, and to do all such services as shall be directed by the master or board.

17. The *warden of the mint* is in conjunction with the master and comptroller, and with the assistance of the king's assayer, to make the weights of a guinea and of a shilling, according to the establisned standards, and also parts and multiples of the same, to be presented to council, and, if approved, to become standard weights, to be lodged in the mint: to have the custody of the said weights at the mint, in conjunction with the master and comptroller: to make also, in conjunction with the master and comptroller, and with the assistance of the king's assayer, copies or duplicates of the said weights, to be lodged with an officer called the stamper of money weights: to summons once, or oftener, in every year, by warrant under the hands of himself, the master and comptroller; the stamper of money weights to appear before them, and produce the said duplicates of the standard weights, to be examined and compared with the standard weights lodged at the mint office in their custody: to pay the salary allowed to the stamper of money weights out of monies to be entrusted to him for that service by the master of the mint.

No person to be appointed to act as deputy to the warden, without the sanction of the lords of the treasury.

18. The *stamper of money weights* is to attend the summons of the warden, master, and comptroller, and to have the duplicate weights in his possession compared with the standard weights at the office, at least once a year: to adjust the duplicate weights by the said standard weights, that all weights for weighing gold and silver money may be regulated by the said duplicates: to stamp the weights made use of in weighing the money, receiving a fee of one penny on every twelve weights stamped or marked pursuant to act of parliament: no other weights but those stamped by the stamper of weights, to be accepted by law, for determining the weight of the coins; and persons counterfeiting the stamps, or altering weights so stamped, to be fined and imprisoned: not to interfere with the weights of the founders' company, if they have their weights sized and marked as above: to receive the salary allowed to his office from the warden or his deputy.

19. The *solicitor of the mint* is to attend the board of mint officers every Wednesday, or such other day as may be appointed, to lay before them such information and depositions, in regard to persons offending against the laws relating to coin, and to receive the board's orders for acting thereupon: to act in conformity to such order, in the prosecution of all such persons as shall clip, counterfeit, melt down, wash, file, or diminish the current coin of the kingdom, or alter any counterfeit coin, knowing the same to be counterfeit, or be guilty of any crime or offence concerning the said coin or money, or against the laws relating to them.

For the better carrying on of the prosecutions that may happen, at the same time, in different counties, to substitute and employ such other person as he shall see fit in his stead: to make out quarterly accounts of the expenses of the prosecutions, with the proper vouchers, to be examined by the board of mint officers, showing the disbursements made by him; and to make an abstract account at the end of every year, of monies received and expended, that the balance may be ascertained and the account discharged.

20. *The general instructions for the common duties of the principal officers*, i. e. *the deputy-master and worker, king's assayer, comptroller, superintendant of the machinery, and king's clerk.*

i. To make their ordinary habitations and abode in houses assigned them within the mint: to meet in the board-room at the mint office every Wednesday (after the delivery of the monies), or on such other day and hour as the master or the service of the mint shall require, there to form a board. Three members (the master or his deputy being one) are competent to act.

ii. To consult together, and order all business appertaining to them concerning the office, determining the hours of attendance of the several officers, the receipts of the bullion, and the delivery of coin: to consider and give directions to the solicitor of the mint, from information laid by him before the board, for undertaking prosecutions for offences relating to the coin, and require him to report, from time to time, as to the state of the prosecutions and convictions.

iii. To take up and employ such smiths, workmen, and laborers, as may be severally wanted in the die department and assay offices; and for assisting in the porterage and weighing of the bullion and coin in the office of receipt, and to order the superintendant of machinery, and clerk of the irons, to purchase or procure to be forged all such dies as are necessary for the coinage or service of the mint, and to provide all necessaries, and do all manner of business within the mint as may be needful.

iv. To observe, follow, and perform, all orders, warrants, or significations of the master and worker, whether grounded upon warrants from the king, the lords of the committee of council

for coin, or the lords commissioners of the treasury; and in all things to obey jointly or severally, in their respective places, such directions as he shall from time to time judge necessary and fit to give for the service of the mint.

v. To see that the accounts of the office for the receipt of the bullion and delivery of the coin, as well as the check and control thereof, be kept in due manner as prescribed, and that the comptrolment roll of the monies coined monthly, be exhibited yearly to the auditors of public accounts.

vi. To see also that the receipts and payments of all monies, for the service of the mint, be charged and accounted for in the master's public account, and that all bills, accounts, and statements, belonging thereto, be examined and allowed under at least three signatures of the principal officers, of which the master's deputy is to be one, previously to its being laid before the audit office: also to examine and report to the lords commissioners of the treasury on the fees derived to the master's office; and the application thereof, pursuant to the act 39 Geo. III., as stated in the receiver's account; in order that the same may be declared and passed.

vii. To prescribe to the under officers and servants, their several charges and duties, and to see the due performance of them; and, in case of negligence or unfaithful conduct, to report to the master, or, as far as the board are authorised, remove them from their situations: not to suffer the works of the mint to be viewed without an order signed by the master; or any stranger or foreigner, not having business at the mint, without any knowledge of his quality, to have intercourse with the officers while performing their duties.

The foregoing official rules will give the reader a general impression of the business conducted at this establishment: we shall now endeavour to conduct him through the several *offices* as they are ordinarily engaged in performing it.

From the bank of England almost all the coined money of the kingdom is first received in the shape of bullion; which is sent to the 'master of the mint's assay office', and received into what is called the *strong-hold*, where it is kept until its fineness is ascertained, in order that its value may be computed.

This being ascertained, the parties concerned are desired to attend at the office of *receipt and delivery* to witness its weight, and to be informed of its fineness, and, consequently, of its value; the standard weight of the bullion being determined by the calculation of the respective offices: a mint-bill is now handed to the owner or owners of the bullion, on which the exact value of that deposit is recorded.

The next thing is to deliver the bullion to the *melting-house*, which is furnished with a variety of apparatus, adapted, not only to the melting of the gold and silver, but the lifting in and out the pots containing the precious metals, with safety, ease, and expedition. The silver is melted in pots of cast-iron, but the gold is melted in smaller pots manufactured from black-lead, which, according to the modern chemistry, is a carburet of iron. The silver is run into plates ten inches long, seven wide, and about five-eighths of an inch thick: the gold-plates are ten inches in length, four in breadth, and three-eighths of an inch in thickness. While the metal is pouring into the moulds, there are three portions taken, from the top, the middle, and bottom of each pot, and carried to the king's assay-office, there to be examined by the master of that office, and not permitted to pass into work until the fineness of the metal is accurately determined. The furnaces used are air-furnaces, and the fuel is coke. In the process of melting, as there will necessarily be waste, every thing that can possibly contain any portion of the precious metals, such as the sweepings of the melting-house, &c., are collected and carried to another apartment, in which are erected two grinding and two triturating mills, where the sweep is worked up, and the fine metals in part recovered, in the manner practised by refiners and goldsmiths.

The *sweep*, thus brought together, is ground into a powder, and passed through a fine sieve, by which the larger grains of metal are obtained. The sweep is then put, in small portions, into a wooden bowl, having two iron handles, by which it is carefully washed: the lighter particles, being absorbed by the water, are collected in a large tub; the heavy or metallic ones are found deposited at the bottom of the bowl. By these means the most considerable of the particles of gold and silver are obtained. The powdered sweepings, however, which have been collected after the washing process, still contain portions of metal; to obtain these, the sweep, in certain portions, is put into a mill, containing generally about 100 cwt of mercury, the remainder of the mill being filled with water: this is commonly called the triturating mill, and each charge is agitated about four hours with an instrument, having four arms placed horizontally, in the shape of a cross, and fixed to the centre of the mill; and, for the better agitation of the sweep and mercury, the motion of this mill can be reversed at pleasure.

From the melting-house, the plates, provided they are found by the assay-master to be of the exact degree of fineness, are carried to the *rolling-mill*. They are first hot-rolled, that is, made red-hot, in a furnace adapted to the purpose, and then passed through a pair of cast-iron rollers. In the room in which this operation is performed there are four pairs of rollers, which (as they require an immense power) are put in motion by a steam-engine, of a power equal to that of thirty horses. The rollers are placed very near the furnaces, and the metal, being brought to what is called a blood-red heat, is taken out by a man with a pair of smith's tongs, and immediately returned by another man, and again passed through while hot two or three times, by which it is greatly extended; after this. it is annealed. This is called the breaking-down rolling, and when finished the plates of silver are about three-sixteenths of an inch thick. They are then cut into slips by a pair of circular shears attached to the shafts, by which the rollers are worked, after which they are finished in what

are called the adjusting-rollers, which are also made of cast-iron, and very finely polished. In this process the slips are rolled cold, and, when a piece cut from the middle of each is found of the proper standard weight, they are carried to another apartment, called the cutting-out room, containing twelve machines worked by a steam-engine of the power of sixteen horses. With these machines the blank pieces are cut out from the strips or laminæ just mentioned with great ease and velocity. The only manual labor required, is that performed by a boy nine or ten years old at each machine; he quickly learns the art of presenting the laminæ to the cutters, which instantly cut out the blank pieces of metal; these so struck fall through a hole that conducts to a box placed below to receive them. Each machine will cut sixty pieces in a minute, of course the twelve will produce 720 in a minute, or 43,200 in an hour. Formerly these machines were worked by hand by a man or boy at each cutter, but no manual labor can operate so accurately and well as the power obtained by the steam-engine. The instruments with which the blanks are cut (called a bed and punch), are made of steel, of the exact diameter of the piece of money required.

The blanks are now carried to the *adjusting-room*, where every piece is most accurately weighed, the gold twice, at least, and the silver once; those pieces that are found too heavy are reduced by the file, called a float, and those that are found too light, which occasionally occurs, are re-melted.

The blanks, properly adjusted, are then conveyed to the *milling-room*. Into this no stranger is allowed to enter; the process of milling being a secret by the very constitution of the mint: and this has always been the case since the time of Peter Blondeau, who introduced the milling in 1662, as appears from Folkes's 'tables of English silver coins.' The blanks, when milled, are annealed, or softened, in order that they may be fitted to receive the impression.

The next operations are *pickling and cleaning*. The process of pickling is to throw the pieces of gold, thus annealed, into a strong solution of super-sulphate of alumine; those of silver into a solution of the super-sulphate of potash. The drying and cleaning is performed by agitation in sieves, containing saw-dust, over a gentle heat.

The pieces are now taken to what is properly called the *coining-room*. In this apartment there are eight coining-presses worked by a ten horse power steam-engine; the apartment also is, in the winter months, heated with steam, so as to be kept to a uniform temperature. The machines are worked with the most perfect accuracy, and with such rapidity that each will produce about sixty in a minute; and on the average, allowing for the necessary delays in working forty pieces of money, that is 320 guineas, &c., will pass through the eight machines in a minute, or about 19,200 in an hour. These machines require also one boy of ten or twelve years of age to each, who, by supplying the machine with the planchets, runs no risque of injury to his fingers, as the machine contains in itself a self-feeder or layer-on; the business of the boy being only to fill the layer-on, through a tube, with the blanks. From this tube, the machine places the blanks upon the dye, and when struck displaces one piece and replaces another, and so on as long as the steam-engine is kept at work. The coin thus completed is carried to the mint-office, where the king's assayer attends, and where the process called Pixing (which see), takes place, to ascertain the weight and fineness of the monies before delivery. Both faces of the coin are struck at once, the upper and under dye being both engraved for the purpose. The dyes are the workmanship of some capital engraver; he, of course, makes the pattern upon soft steel: from this, many others are taken at an office in the mint, and hardened. The engraver is called upon to verify the accuracy of the dies made use of, with the pattern or mould which he has furnished. See Money, and Monetary Art.

MINTO (Walter), LL. D., professor of mathematics in the college of New Jersey, was born at Minto in Roxburghshire, about 1755. His father gave him a liberal education, and, having removed with his family to Edinburgh, young Walter passed through the usual course of education, with the intention of studying divinity. His education was newly completed when he received an offer of a very lucrative situation from an uncle, who having made money in Jamaica, and purchased a plantation, wished his nephew to come and superintend it as overseer. But he yielded this appointment to his younger brother rather than have any connexion with the slave trade. Meantime, while he was waiting for an opportunity of a vacancy among the churches of the Associate Synod, an offer of an appointment was made to him by David Hume, to accompany two sons of governor Johnstone as a tutor, in their travels on the continent. This proposal was readily accepted, and in consequence of it he spent several years abroad, particularly at Pisa in Italy, and became acquainted with a number of the Italian literati, particularly with the celebrated Dr. Joseph Slop, of Cadenberg, professor of astronomy in the university of Pisa, and member of the academy of Bononia. He returned to Edinburgh in 1783; obtained the degree of LL. D. from the university of Aberdeen; went to America in 1784, by the advice of the earl of Buchan; and not long after obtained the professorship of mathematics and natural philosophy in the college of New Jersey; where he taught those useful branches of science, till the 21st of October, 1796, when he died at Princeton, leaving a widow. He published several treatises; particularly, 1. Researches into some parts of the Theory of th Planets, 8vo. London, 1783. 2. An Inaugural Oration on the Progress and Importance of the Mathematical Sciences, 8vo., Trenton, 1788. He also wrote, in conjunction with the earl of Buchan, 3. An Account of the Life, Writings, and Inventions of John Napier of Merchiston, 4to. Perth; wherein the origin of geometry, arithmetic, &c., is treated at considerable length.

MINTURNÆ, a town of Campania, between Sinuessa and Formiæ. In the marshes near it Marius concealed himself in the mud to avoid

the partizans of Sylla. The people condemned him to death; but when his voice alone had terrified the executioner, they favored his escape. See MARIUS.

MINUET', *n. s.* Fr. *minuet;* Ital. *minuto;* perhaps of Lat. *minute,* nice, skilful. A stately regular dance.

The tender creature could not see his fate,
With whom she danced a *minuet* so late.
Spenser.

John has assurance to set up for a *minuet* dancer.
Spectator.

MIN'UM, *n. s.* Lat. *minus.* A small sort of printing letter; also a note of slow time, two of which make a semibrief, as two crotchets make a minum.

He's the courageous captain of compliments; he fights as you sing pricksongs, keeps time, distance, and proportion: rests his *minum,* one, two, and the third in your bosom. *Shakspeare.*

MINUTE', *adj.* & *v. a.* } Lat. *minutus.* Small,
MIN'UTE-BOOK, } slender in bulk or
MINUTE'LY, *adj.* } appearance; incon-
MINUTE'NESS, *n. s.* } siderable: to minute
is to make small or short hints or memoranda: a minute-book, the book used for such purpose: minutely and minuteness, exactly or nicely; smallness; inconsiderableness.

Some *minute* philosophers pretend,
That with our days our pains and pleasures end.
Denham.

In this posture of mind it was impossible for him to keep that slow pace, and observe *minutely* that order of ranging all he said, from which results an obvious perspicuity. *Locke.*

I no sooner heard this critick talk of my works, but I *minuted* what he had said, and resolved to enlarge the plan of my speculations. *Spectator.*

Such an universal superintendency has the eye and hand of providence over all, even the most *minute* and inconsiderable things. *South's Sermons.*

Into small parts the wondrous stone divide,
Ten thousand of *minutest* size express
The same propension which the large possess.
Blackmore.

The serum is attenuated by circulation, so as to pass into the *minutest* channels, and become fit nutriment for the body. *Arbuthnot.*

The animal spirit and insensible particles never fall under our senses by reason of their *minuteness.*
Bentley.

In all divisions we should consider the larger and more immediate parts of the subject, and not divide it at once into the more *minute* and remote parts.
Watts's Logic.

Change of night and day,
And of the seasons ever stealing round,
Minutely faithful. *Thomson's Summer.*

General history cannot descend to *minute* details of domestick life and private transactions, the passions and foibles of great personages, &c. *Johnson.*

I do by no means advise you to throw away your time in ransacking, like a dull antiquarian, the *minute* and unimportant parts of remote and fabulous times.
Chesterfield.

MIN'UTE, *n. s.* } Lat. *minutum.* The six-
MIN'UTE-GLASS, } tieth part of an hour: any
MIN'UTE-WATCH. } small part of time: the
minute-glass and watch mark the period in question.

Tell her that I some certainty may bring;
I go this *minute* to attend the king. *Dryden.*

Casting our eyes upon a *minute-watch,* we found that from the beginning of the pumping, about two *minutes* after the coals had been put in glowing, to the total disappearing of the fire, there had passed but three *minutes.* *Boyle.*

MINX, *n. s.* Contracted probably from MINNOCK, which see. A young, pert, wanton girl.

Lewd *minx!*
Come, go with me apart. *Shakspeare.*

Some torches bore, some links,
Before the proud virago *minx.* *Hudibras.*

She, when but yet a tender *minx,* began
To hold the door, but now sets up for man.
Dryden.

MINYÆ, the ancient inhabitants of Orchomenos in Bœotia, so named from Minyas king of the country. Orchomenos the son of Minyas gave his name to the capital; but the inhabitants still retained their original appellation, in contradistinction to the Orchomenians of Arcadia. A colony of Orchomenians passed into Thessaly and settled in Iolchos; and were called Minyæ; because their chiefs were descended from the daughters of Minyas. Part of the Orchomenians accompanied the sons of Codrus when they migrated to Ionia. The Argonauts, as well as their descendants, received likewise the name of Minyæ. They were driven from Lemnos by the Pelasgi about A. A. C. 1160, and came to settle in Laconia, whence they passed into Calliste with a colony of Lacedemonians.

MINYAS, in fabulous history, a king of Bœotia, the son of Neptune by Ttitegenia, daughter of Æolus. He had six sons, of whom the most famous were Orchomenos and Athamas; and three daughters.

MIQUELETS; the inhabitants of the Southern Pyrenees, in Catalonia, and in the French departments of the Upper and Eastern Pyrenees, on the heights of the chain of mountains which forms the boundary between France and Spain. They are mostly herdsmen, hunters, coal-burners, &c. They are warlike, and inclined to plunder. They also accompany travellers on the mountain-passes, and receive high pay for their protection. In war, they are dangerous partisans, who often descend into France in troops. In the war with Napoleon, they made themselves formidable to the French troops in Catalonia.

MIQUELON; an island in the Atlantic ocean, near the southern coast of Newfoundland, belonging to France; lat. 57° 4' N.; lon. 56° 20 W. To the scuth of it lies Little Miquelon (*Petite Miquelon*), which, since 1783, has been connected with it by a sand-bank. These islands are under the direction of the commandant of St. Pierre, and are occupied only by a few families engaged in the fisheries.

MIRABEAU, count or marquis Mirabeau, a French nobleman celebrated for his literary attainments, and founder of the sect of Œconomists. He enjoyed several important offices under government. Besides several other pieces he published a famous work, entitled L'Ami des Hommes, or the Friend of Mankind. He died in 1786.

MIRABEAU (Gabriel Honore Riquteti count,

the eldest son of the preceding. was born in Paris, in 1749. He showed grea. abilities at an early age; but, having been guilty of some juvenile indiscretions, his father treated him with so much severity that he fled from his persecutions in 1769, and took refuge in Holland; where he published a book against despotism both regal and paternal. On his return to France, he was seized on a lettre de cachet, obtained by his father, and shut up in a state prison; but the walls of a dungeon could not damp the vigor of his mind, nor repress the activity of his genius; for, amidst the gloom and melancholy of a rigorous confinement, he wrote his much admired work on Lettres de Cachet, which was published soon after he had obtained his liberty, and circulated through France, and soon after through all Europe. But, while his literary fame was thus rising, his moral character was sullied by repeated scenes of dissipation, which his father in vain endeavoured to repress by successive imprisonments, insomuch that it is said he had obtained no fewer than thirty, Dr. Watkins says sixty-seven, lettres de cachet against him. But, while the old count was even meditating how to disinherit him, young Gabriel was released from farther persecution by his death. Soon after this, he travelled through Germany, Switzerland, England, and Flanders; and, upon his return, was appointed by M. de Calonne a kind of private envoy to the court of Berlin, Frederick the Great being then in his decline, and the French court wishing to be acquainted with the genius and capacity of the prince royal. The count fulfilled the object of his mission with success, and disclosed the situation, the views and characters of the Prussian court, in a work that attracted the attention of all Europe. This work was entitled The Secret History of the Court of Berlin, and was condemned by the parliament of Paris. Yet at this period the count's ambition aspired no higher than to fill some inferior diplomatic office. But M. de Calonne either did not justly appreciate his abilities, or viewed them with envy; for he neither gave him a new appointment, nor properly rewarded him for what he had done. But Mirabeau was ordained soon to figure in a much more conspicuous situation. At the meeting of the States of Provence, in 1787, he delivered an oration, which not only procured him the highest applause for his eloquence and patriotism, but inspired all who heard it with the same zeal for liberty and hatred of despotism that seemed to influence himself. This memorable oration procured him to be elected a member of the Constituent National Assembly, both by the citizens of Marseilles and those of Aix. He took his seat for the latter, and soon distinguished himself as the most able advocate that France had seen for the rights of the people. In that assembly of the greatest and most learned men that France ever convened together, Mirabeau was elected president. But his patriotic career was ordained to be short. In the midst of his glory and of his schemes for the permanent establishment of a free constitution under a limited monarchy, he was seized with a rheumatic gout, which from its commencement prognosticated a fatal issue. All Paris was in anxious alarm, but although he had the best medical advice he died on the 2nd of April, 1791. He continued to the last to talk of public affairs, and, when no longer able to converse, expressed his sentiments on some important subjects in writing. His works consist of eighteen treatises, chiefly in favor of democracy.

MIRABILIS, marvel of Peru, a genus of the monogynia order and pentandria class of plants: COR. funnel-shaped above: CAL. inferior; the nectarium globular, containing the germen. The most remarkable species are these:—

1. M. dichotoma, the dichotomous, or forked marvel, has a thick fleshy root, an upright, thick, swollen, jointed stem, branching forkedly two or three feet high; oblong opposite leaves, and smallish red flowers at the axillas, singly and close-sitting.

2. M. jalappa, the common marvel of Peru. It has a large, thick, fleshy root, an upright, thick, jointed stalk, dividing and branching numerously, widely, and erectly, a yard or more high; garnished with oblong, broad, opposite leaves; and all the branches and shoots terminated by numerous flowers in clusters, of different colors in the varieties. Of these there are varieties with, 1. white flowers; 2. yellow; 3. purple; 4. red; 5. white and yellow; 6. white and purple; 7. purple and yellow; 8. red and yellow flowers. Several other varieties often rise from seed; but, although several of the above colors and variegations are sometimes common to the same plant, yet it is rare that a plant of this species produces flowers of one of these colors alone; sometimes, however, the same plant will exhibit only white and purple flowers separate, and sometimes both colors in the same flowers, intermixed with the plain ones; the same is also observable in the red and yellow; others have plain flowers of several different colors, and sometimes of variegated flowers also on the same plant. This species has a large tap root, which, when cut across, resembles that of the true jalap; but, when dried, is white, light, and spongy.

3. M. longiflora, or the long flowered marvel, has a large, thick, and fleshy root, a thick stalk, dividing low into many declinated spreading branches, extending two or three feet every way; large heart-formed, hairy, viscous leaves, in opposite pairs; and all the branches and shoots terminated by white flowers in clusters, having very long tubes, nodding downward. All these plants flower in July, continuing in plentiful succession until October, very conspicuous and elegant. They have the singularity of being shut all day, and expanding towards the evening when the sun declines; hence the inhabitants of the Indies, where they grow naturally, called them four o'clock flowers; their time of opening here, however, depends on the weather; for if cloudy, or that the sun is not very vehement, they often open great part of the day. They are naturally perennial in root; but in this country are commonly considered as annuals; for they rise from seed in the spring, and the same year produce flowers and perfect

seed; and, if left to nature in the open air, totally perish in winter, at the first attack of frost or excessive rain. If in autumn, however, when the stalks begin to assume a state of decay, the roots are taken up, preserved in sand in a dry room, and planted again in spring, they shoot out afresh stronger than at first, and sometimes rise four or five feet high, with very spreading heads; or if plants growing in pots having the stems cut down in autumn, and the pots placed in a green-house, or garden frames under glasses, the roots may also be preserved sound, and will shoot out again in spring as above. The roots of all these plants are purgative; but require to be given in a great quantity to operate.

MIR'ACLE, *n. s.*
MIRAC'ULOUS, *adj.*
MIRAC'ULOUSLY, *adv.*
MIRAC'ULOUSNESS, *n. s.*
Fr. *miracle*; Lat. *miraculum*, of *miror*, to wonder. A supernatural effect or event: miraculous, by miracle, marvellous; the adverb and substantive corresponding.

And many camen to him, and seiden for dide no *miracle*. *Wiclif. John* x.

It was a singular providence of God, to draw those northern heathen nations down into those Christian parts, where they might receive Christianity, and to mingle nations so remote *miraculously* to make one blood and kindred of all people, and each to have knowledge of him. *Spenser on Ireland.*

Nothing almost sees *miracles*
But misery. *Shakspeare. King Lear*
Be not offended, nature's *miracle*,
Thou art allotted to be ta'en by me.
Shakspeare.

Arithmetical progression might easily demonstrate how fast mankind would increase, overpassing as *miraculous*, though indeed natural, that example of the Israelites, who were multiplied in two hundred and fifteen years from seventy unto six hundred thousand able men. *Raleigh's Essays.*

Restore this day, for thy great name,
Unto his ancient and *miraculous* right. *Herbert.*

Either the sun goes back in heaven, that his shadow may go back on earth; or the shadow no less *miraculously* goes back on earth, while the sun goes forward in heaven. *Bp. Hall.*

Why this strength
Miraculous yet remaining in those locks?
His might continues in thee not for naught.
Milton.

We may observe both their expectation of *miraculous* works from the Messias, and the efficacy which such works had upon them. *Barrow.*

At the first planting of the Christian religion, God was pleased to accompany it with a *miraculous* power. *Tillotson.*

Turnus was to be slain that very day; and Æneas, wounded as he was, could not have engaged him in single combat, unless his hurt had been *miraculously* healed. *Dryden.*

The *miracles* of our Lord are peculiarly eminent above the lying wonders of demons, in that they were not made out of vain ostentation of power, and to raise unprofitable amazement; but for the real benefit and advantage of men, by feeding the hungry, healing all sorts of diseases, ejecting of devils, and reviving the dead. *Bentley.*

The third by agriculture, the only honest way, wherein man receives a real increase of the seed thrown into the ground, in a kind of continal *miracle*, wrought by the hand of God in his favour. *Franklin.*

MIRACLE is defined by Dr. (now bishop) Gleig, 'an effect contrary to the established constitution and course of things, or a sensible deviation from the known laws of nature. That the universe (continues he) is governed by stated general rules, or that there is an order of causes and effects established in every part of the visible system of nature, is a fact which cannot be controverted. If the Supreme Being be the only real agent in the universe we have the evidence of experience, that, in the particular system to which we belong, he acts by stated rules. If he employs inferior agents to conduct the various motions from which the phenomena result, we have the same evidence that he has subjected those agents to certain fixed laws, commonly called the laws of nature. On either hypothesis, effects which are produced by the regular operation of these laws, or which are conformable to the established course of events, are properly called natural; and every deviation from this constitution of the natural system, and the correspondent course of events in it, is called a miracle. If this definition be just, no event can be deemed miraculous merely because it is strange, or even to us unaccountable; since it may be nothing more than a regular effect of some unknown law of nature. In this country earthquakes are rare; and for monstrous births perhaps no particular and satisfactory account can be given: yet an earthquake is as regular an effect of the established laws of nature as any of those with which we are most intimately acquainted; and, under circumstances in which there would always be the same kind of production, the monster is nature's genuine issue. It is therefore necessary, before we can pronounce any effect to be a true miracle, that the circumstances under which it is produced be known, and that the common course of nature be in some degree understood; for, in all those cases in which we are totally ignorant of nature, it is impossible to determine what is, or what is not, a deviation from its course. Miracles therefore are not as some have represented them, appeals to our ignorance. They suppose some antecedent knowledge of the course of nature, without which no proper judgment can be formed concerning them; though with it their reality may be so apparent as to prevent all possibility of a dispute. Thus, were a physician to cure a blind man of a cataract, by anointing his eyes with a chemical preparation which we had never before seen, and to the nature and effects of which we are absolute strangers, the cure would undoubtedly be wonderful; but we could not pronounce it miraculous, because, for any thing known to us, it might be the natural effect of the operation of the unguent on the eye. But were he to recover his patient merely by commanding him to see, or by anointing his eyes with clay and spittle, we should with the utmost confidence pronounce the cure to be a miracle; because we know perfectly that neither the human voice nor human saliva has, by the established constitution of things, any such power over the diseases of the eye. No one is now ignorant that persons apparently dead are often restored to their families and friends, by being treated in the manner recommended by the Humane Society. To the vulgar, and sometimes even to men of science, these

effects appear very wonderful; but, as they are known to be produced by physical agency, they can never be considered as miraculous deviations from the laws of nature. On the other hand, no one could doubt of his having witnessed a real miracle who had seen a person that had been four days dead come alive out of his grave at the call of another, or who had even beheld a person exhibiting all the symptoms of death instantly resuscitated, merely by being commanded to live. Thus it is easy, in all cases in which the course of nature is understood, to determine whether any particular event be really a miracle; while in circumstances where we know nothing of nature and its course, even a true miracle could not be admitted as such, or carry any conviction to the mind of a philosopher. If miracles be effects contrary to the established constitution of things, we are certain that they will never be performed on trivial occasions. The constitution of things was established by the Creator and Governor of the universe, and is undoubtedly the offspring of infinite wisdom pursuing a plan for the best of purposes. From this plan no deviation can be made but by God himself, or by some powerful being acting with his permission. The plans of infinite wisdom must be absolutely perfect. From this consideration, some have concluded that no miracle was ever wrought, or can rationally be expected; but mature reflection must satisfy us that all such conclusions are hasty. Man is unquestionably the principal creature in this world, and apparently the only one in it who is capable of being made acquainted with the relation in which he stands to his Creator. We cannot, therefore, doubt but that such of the laws of nature as extend not their operation beyond the limits of this earth, were established chiefly, if not solely, for the good of mankind; and if, in any particular circumstances, that good can be more effectually promoted by an occasional deviation from those laws, such a deviation may be reasonably expected. Were man, in the exercise of his mental and corporeal powers, subjected to the laws of physical necessity, the circumstances supposed would indeed never occur, and, of course, no miracle could be admitted. But such is not the nature of man.'

'Without repeating what has been said under Metaphysics,' continues this writer, 'of necessity and liberty, we shall take it for granted, that the relation between motive and actions, is different from that between cause and effect in physics; and that mankind, by their voluntary conduct, can make themselves in a great degree either happy or miserable. We know likewise from history that almost all mankind were once sunk in the grossest ignorance of the most important truths; that they knew not the Being by whom they were created and supported; that they worshipped stocks, stones, and the vilest reptiles; and that they were slaves to the most impious, cruel, and degrading superstitions. From this depraved state it was surely not unworthy of the common Father of All to rescue his helpless creatures, to enlighten their understandings that they might perceive what is right, and to present to them motives of sufficient force to engage them in the practice of it. But the understandings of ignorant barbarians cannot be enlightened by arguments; because of the force of such arguments, as regard moral science, they are not qualified to judge. The philosophers of Greece and Rome inculcated, indeed, many excellent moral precepts, and they sometimes ventured to expose the absurdities of the reigning superstition; but their lectures had no influence upon the multitude; and they had themselves imbibed such erroneous notions respecting the Supreme Being, and the nature of the human soul, and established those notions as first principles, of which they would not permit an examination, that even among them a thorough reformation was not to be expected from the powers of reasoning. It is likewise to be remarked that there are many truths, of the utmost importance to mankind, which unassisted reason could never have discovered. Among these we may reckon the immortality of the soul, the terms upon which God will be reconciled to sinners, and the manner in which the all-perfect Being may be acceptably worshipped; about all of which philosophers were in such uncertainty that, according to Plato, 'Whatever is set right, and as it should be, in the present evil state of the world, can be so only by the particular interposition of God.' (De Repub. Lib. 6). An immediate revelation from heaven, therefore, was the only method by which infinite wisdom and perfect goodness could reform a bewildered and vicious race. But this revelation must have been made directly either to some chosen individuals commissioned to instruct others, or to every man and woman for whose benefit it was ultimately intended. Were every person instructed in the knowledge of his duty by immediate inspiration, and were the motives to practise it brought home to his mind by God himself, human nature would be wholly changed: men would not be masters of their own actions; they would not be moral agents, nor be capable either of reward or punishment. It remains, therefore, that if God has been graciously pleased to enlighten and reform mankind, without destroying that moral nature which is essential to virtue, he can have done it only by revealing his truth to certain persons chosen to be the immediate instructors of their contemporaries, and through them of succeeding ages. Let us suppose this to have been the case, and consider how these inspired teachers could communicate to others every truth which had been revealed to themselves. They might easily deliver a sublime system of natural and moral science, and establish it upon the common basis of experiment and demonstration; but what foundation could they lay for those truths which unassisted reason cannot discover, and which, when revealed, appear to have no necessary relation to any thing previously known? To a bare affirmation that they had been immediately received from God, no rational being could be expected to assent. The teachers might be men of known veracity, whose simple assertion would be admitted as sufficient evidence for any fact, in conformity with the laws of nature; but, as every man has the evidence of his own consciousness and experience that revelations from heaven are deviations

from these laws, an assertion so apparently extravagant would be rejected as false, unless supported by some better proof than the mere assertion of the teacher. In this state of things, we can conceive no evidence sufficient to make such doctrines be received as the truths of God, but the power of working miracles committed to him who taught them. This would, indeed, be fully adequate to the purpose. For if there were nothing in the doctrines themselves impious, immoral, or contrary to truths already known, the only thing which could render the teacher's assertion incredible, would be its implying such an intimate communion with God as is contrary to the established course of things, by which men are left to acquire all their knowledge by the exercise of their own faculties. Let us now suppose some one of those inspired teachers to tell his countrymen that he did not desire them, on his ipse dixit, to believe that he had any preternatural communion with the deity, but that for the truth of his assertion he would give them the evidence of their own senses; and, after this declaration, let us suppose him immediately to raise a person from the dead in their presence, merely by calling upon him to come out of his grave. Would not the only possible objection to the man's veracity be removed by this miracle? and his assertion that he had received such and such doctrines from God be as fully credited as if it related to the most common occurrence? Undoubtedly it would; for, when so much preternatural power was visibly communicated to this person, no one could have reason to question his having received an equal portion of preternatural knowledge. A palpable deviation from the known laws of nature, in one instance, is a decisive proof that such a deviation is possible in another; and, in such a case as this, it is the testimony of God to the truth of a man. Miracles, then, under which we include prophecy, are the only direct evidence which can be given of divine inspiration. When a religion, or any religious truth, is to be revealed from heaven, they appear to be absolutely necessary to enforce its reception among men; and this is the only case in which we can suppose them necessary, or believe that they ever have been or will be performed. The history of almost every religion abounds with relations of prodigies and wonders, and of the intercourse of men with the gods; but we know of no religious system, those of the Jews and Christians excepted, which appealed to miracles as the sole evidence of its truth and divinity. The pretended miracles mentioned by Pagan historians and poets are not said to have been publicly wrought to enforce the truth of a new religion contrary to the reigning idolatry. Many of them may be clearly shown to have been mere natural events. See Magic. Others are represented as having been performed in secret on the most trivial occasions, and in obscure and fabulous ages long prior to the era of the writers by whom they are recorded. And such of them as at first view appear to be best attested are evidently tricks contrived for interested purposes: to flatter power, or to promote the prevailing superstitions. For these reasons, as well as on account of the immoral character of the divinities by whom they are said to have been wrought, they are altogether unworthy of examination, and carry in the very nature of them the completest proofs of falsehood and imposture. But the miracles recorded of Moses and of Christ bear a very different character. None of them is represented as wrought on trivial occasions. The writers who mention them were eye-witnesses of the facts; which they affirm to have been performed publicly, in attestation of the truth of their respective systems. They are indeed so incorporated with these systems that the miracles cannot be separated from the doctrines; and, if the miracles were not really performed, the doctrines cannot possibly be true. They were also wrought in support of revelations which opposed all the religious systems, superstitions, and prejudices, of the age in which they were given: a circumstance which of itself sets them, in point of authority, infinitely above the Pagan prodigies, as well as the lying wonders of the Romish church. It is indeed universally admitted, that the miracles mentioned in Exodus and the Gospels might, to those who saw them performed, be sufficient evidence of the divine inspiration of Moses and of Christ; but to us it may be argued that they are no evidence whatever, as we must believe in these miracles upon the bare authority of human testimony. Why, it has been asked, are not miracles wrought in all ages and countries? If the religion of Christ was to be of perpetual duration, every generation of men ought to have complete evidence of its truth and divinity. To the performance of miracles in every age and in every country, the same objections lie as to the immediate inspiration of every individual. The very end of all miracles would be defeated by their frequency. Miracles so often repeated would have no authority, because it would be difficult, if not impossible, to distinguish them from natural events. If they recurred regularly, at certain intervals, we could not prove them to be deviations from the known laws of nature, because we should have the same experience for the regular succession of preternatural effects, as for the established constitution and course of things. We may farther affirm, that for the reality of the Gospel miracles we have evidence as convincing to the reflecting mind, though not so striking, as those had who were contemporary with Christ and his apostles. and actually saw his mighty works. To the admirers of Mr. Hume's philosophy this assertion will appear an extravagant paradox; but we hope to demonstrate its truth from principles, which, consistently with himself, that author could not have denied. He has indeed endeavoured to prove (in his Essay on Miracles), that 'no testimony is sufficient to establish a miracle;' and the reasoning employed for this purpose is, 'that a miracle being a violation of the laws of nature, which a firm and unalterable experience has established, the proof against a miracle, from the nature of the fact, is as entire as any argument from experience can be; whereas our experience of human veracity, which (according to him), is the sole foundation of the evidence of testimony, is far from being uniform, and can never preponderate against that experience

which admits of no exception.' This boasted and plausible argument has with equal candor and acuteness been examined by Dr. Campbell, in his Dissertation on Miracles, who justly observes, that so far is experience from being the sole foundation of the evidence of testimony, that, on the contrary, testimony is the sole foundation of by far the greater part of what Mr. Hume calls firm and unalterable experience; and that if, in certain circumstances, we did not give an implicit faith to testimony, our knowledge of events would be confined to those which had fallen under the immediate observation of our own senses. But though Dr. Campbell has exposed the sophistry of his opponent's reasoning, and overturned the principles from which he reasons, we are persuaded that he might safely have joined issue with him upon those very principles. The testimony upon which we receive the Gospel miracles is precisely of that kind which Mr. Hume has acknowledged sufficient to establish even a miracle. 'No testimony,' says he, 'is sufficient to establish a miracle, unless the testimony be of such a kind that its falsehood would be more miraculous than the fact which it endeavours to establish. When one tells me that he saw a dead man restored to life, I immediately consider with myself whether it be more probable that this person should either deceive or be deceived, or that the fact which he relates should really have happened. I weigh the one miracle against the other; and, according to the superiority which I discover, I pronounce my decision, and always reject the greater miracle.' In this passage every reader may remark, what did not escape the perspicacious eye of Dr. Campbell, a strange confusion of terms; but as all miracles are equally easy to the Almighty, and as Mr. Hume has elsewhere observed, 'that the raising of a feather, when the wind wants ever so little of a force requisite for that purpose, is as real a miracle as the raising of a house or a ship into the air;' candor obliges us to suppose, that by talking of greater and less miracles, and of always rejecting the greater, he meant nothing more, but that, of two deviations from the known laws of nature, he always rejects that which in itself is least probable. If, then, we can show that the testimony given by the apostles and other first preachers of Christianity, to the miracles of their master, would, upon the supposition that those miracles were not really performed, have been as great a deviation from the known laws of nature as the miracles themselves, the balance must be considered as evenly poised by opposite miracles; and, whilst it continues so, the judgment must remain in a state of suspense. But, if it shall appear, that in this case the false testimony would have been a deviation from the laws of nature, less probable in itself than the miracles recorded in the Gospels, the balance will be instantly destroyed; and, by Mr. Hume's maxim, we shall be obliged to reject the supposition of falsehood in the testimony of the apostles, and admit the miracles of Christ to have been really performed. In this argument we need not waste time in proving that those miracles, as they are represented in the New Testament, were of such a nature, and performed before so many witnesses, that no imposition could possibly be practised on the senses of those who affirm that they were present. From every page of the Gospels this is so evident, that the philosophical adversaries of the Christian faith never suppose the apostles to have been themselves deceived, but boldly accuse them of bearing false witness. But, if this accusation be well founded, their testimony itself is as great a miracle as any which they record of themselves or of their master. It has been shown elsewhere that by the law of association, which is one of the laws of nature, mankind, in the very process of learning to speak, necessarily learn to speak the truth; that ideas and relations are in the mind of every man so closely associated with the words by which they are expressed in his native tongue, and in every other language of which he is master, that the one cannot be entirely separated from the other; that therefore no man can on any occasion speak falsehood without some effort; that by no effort can a man give consistency to any premeditated detail of falsehood, if it be of any length, and include a number of particulars; and that it is still less possible for several men to agree in such a detail, when at a distance from each other, and cross-questioned by their enemies. It therefore follows, if the testimony of the apostles to their own and their Master's miracles be false, either that they must have concerted a consistent scheme of falsehood, and agreed to publish it at every hazard; or that God, or some powerful agent appointed by him, must have dissolved all the associations formed in their minds between the ideas of sense and the words of language, and arbitrarily formed new associations, all in exact conformity to each other, but all in direct contradiction to truth. One or other of these events must have taken place, because, upon the supposition of falsehood, there is no other alternative. But such a dissolution and formation of associations as the latter implies, must, to every man who shall attentively consider it, appear to be as real a miracle, and to require as great an exertion of power, as the resurrection of the dead. Nor is the supposed voluntary agreement of the apostles in a scheme of falsehood an event less miraculous. The very resolution of the apostles to propagate the belief of false miracles, in support of such a religion as that which is taught in the New Testament, is as great a miracle as human imagination can easily conceive. When they formed this design, either they must have hoped to succeed, or they must have foreseen that they should fail in their undertaking; and, in either case, they chose evil for its own sake They could not, if they foresaw that they should fail, look for any thing but that contempt, disgrace, and persecution, which were the inevitable consequences of an unsuccessful endeavour to overthrow the established religion. Nor could their prospects be brighter upon the supposition of their success. As they knew themselves to be false witnesses, and impious deceivers, they could have no hopes beyond the grave; and by determining to oppose all the religious systems, superstitions, and prejudices of the ages in which they lived, they wilfully exposed themselves to inevitable misery in the present life, to insult and imprisonment, to stripes and

death. Nor can it be said that they might look forward to power and affluence when they should, through suffering, have converted their countrymen; for so desirous were they of obtaining nothing but misery at the end of their mission, that they made their own persecution a test of the truth of their doctrines. They introduced the Master, from whom they pretended to have received these doctrines, as telling them that 'they were sent forth as sheep in the midst of wolves; that they should be delivered up to councils, and scourged in synagogues; that they should be hated of all men for his name's sake; that the brother should deliver up the brother to death, and the father the child; and that he who took not up his cross and followed after him was not worthy of him.' The very system of religion, therefore, which they invented and resolved to impose upon mankind, was so contrived, that the worldly prosperity of its first preachers, and even their exemption from persecution, was incompatible with its success. Had these clear predictions of the Author of that religion, under whom the apostles acted only as ministers, not been verified, all mankind must have perceived that their pretence to inspiration was false, and that Christianity was a scandalous and impudent imposture. All this the apostles could not but foresee, when they formed their plan for deluding the world. Whence it follows, that, when they resolved to support their pretended revelation by an appeal to forged miracles, they wilfully, and with their eyes open, exposed themselves to inevitable misery, whether they should succeed or fail in their enterprize; and that they concerted their measures so as not to admit of the possibility of a recompense to themselves, either in this life or that which is to come. But if there be a law of nature, for the reality of which we have better evidence than we have for others, it is, that 'no man can choose misery for its own sake,' or make the acquisition of it the ultimate object of his pursuit. The existence of other laws of nature we know by testimony and our own observation of their effects. The existence of this law is known to us not only by these means, but also by the still clearer and more conclusive evidence of our own consciousness. Thus, then, do miracles force themselves upon our assent in every possible view which we can take of this interesting subject. If the testimony of the first teachers of Christianity was true, the miracles recorded in the Gospel were certainly performed, and the doctrines of our religion are derived from heaven. But, if that testimony was false, either God must have miraculously effaced from the minds of those by whom it was given all the associations formed between their sensible ideas and the words of language, or he must have endowed those men with the gift of prescience, and have impelled them to fabricate a pretended revelation for the purpose of deceiving the world, and involving themselves in certain and foreseen destruction. The power necessary to perform the one series of these miracles may be as great as that which would be requisite for the performance of the other; and, considered merely as exertions of preternatural power, they may seem to balance each other, and to hold the mind in a state of suspense. But, when we take into consideration the different purposes for which these opposite miracles were wrought, the balance is instantly destroyed. The miracles recorded in the Gospels, if real, were wrought in support of a revelation, which, in the opinion of all by whom it is received, has brought to light many important truths, which could not otherwise have been made known to men; and which, by the confession of its adversaries, contains the purest moral precepts by which the conduct of mankind was ever directed. The opposite series of miracles, if real, was performed to enable, and even to compel a company of Jews, of the lowest rank, and of the narrowest education, to fabricate, with the view of inevitable destruction to themselves, a consistent scheme of falsehood, and by an appeal to forged miracles to impose it upon the world as a revelation from heaven. The object of the former miracles is worthy of a God of infinite wisdom, goodness, and power. The object of the latter is absolutely inconsistent with infinite wisdom and goodness. Whence it follows that the supposition of the apostles bearing false testimony to the miracles of their Master implies a series of deviations from the laws of nature infinitely less probable in themselves than those miracles; and therefore, by Mr. Hume's maxim, we must necessarily reject the supposition of falsehood in the testimony, and admit the reality of the miracles. So true is it, that, for the reality of the Gospel miracles, we have evidence as convincing to the reflecting mind, as those had who were contemporary with Christ and his apostles, and were actual witnesses to their mighty works.' See THEOLOGY.

MIRANDA, a river of Spain, which, rising among the mountains of Asturias, flows northwards, separates that province from Galicia, and falls into the Atlantic.

MIRANDA DE CORVO, a town of the province of Beira, Portugal, on the river Duca. Population 2700. Twelve miles south-east of Coimbra.

MIRANDA (Francis), a South American revolutionary general, was a native of Peru. He entered first into the Spanish service; and, having made an attempt at Guatimala to free his countrymen, his project was prematurely discovered, and he was obliged to make his escape. He now presented to different European courts plans for the emancipation of the Spanish American colonies; and, thinking at last that the French republican government was more likely to second his schemes, he went to Paris in 1792, and connected himself with the Girondists. While waiting to commence operations in America, Miranda was offered an appointment as general of division in the army of Dumouriez. His conduct at the siege of Maestricht, and at the battle of Nerwinde, did him, it is said, no credit; and some time after he was imprisoned in consequence of his political intrigues. He was liberated in July 1794, but immediately commanded to quit the territories of France, which order he evaded. A second sentence of deportation, in 1797, obliged him to come to England. In 1804 he again repaired to Paris, where his intrigues caused him to be a third time arrested, and to be ordered by the consular government, to leave

France. He returned to America in 1806. Within five years he succeeded in revolutionising a part of the country. In 1811 he endeavoured to established a consular government at Caraccas; but his scheme was ruined by the disputes of his followers. He now fled to Carthagena, where he was taken prisoner by the Spaniards, sent to Cadiz, and thrown into a dungeon, where he remained till his death in 1816.

MIRANDOLA, a considerable fortified and inland town in the states of Modena and Italy, the capital of a province of the same name, situated on the Burana. It is defended by a citadel and castle, called La Rocca, and contains a cathedral, fifteen churches, and 8200 inhabitants, who manufacture silk and linen. Sixteen miles N. N. E. of Modena, and twenty-two south-east of Mantua.

MIRADOR', *n. s.* Span. *mirador*, *mirar*, of Lat. *miror*, to look.

Mean time your valiant son, who had before
Gained fame, rode round, to every *mirador*;
Beneath each lady's stand a stop he made,
And bowing, took the applauses which they paid.
Dryden.

MIRE, *n. s.* & *v. a.* } Belg. *moer*; Goth.
MI'RY, *adj.* } and Swed. *mira*. Mud; dirt; the foul sediment of water; to mire is to overwhelm or bespatter with mud: miry, dirty; abounding with mire.

The dog is turned to his own vomit again, and the sow that was washed to her wallowing in the *mire*.
2 *Pet.* ii. 22.

He his rider from his lofty steed,
Would have cast down, and trod in dirty *mire*.
Spenser.

Here's that, which is too weak to be a sinner, honest water, which ne'er left man i' the *mire*.
Shakspeare. Timon of Athens.

Why had I not, with charitable hand,
Took up a beggar's issue at my gates?
Who smeared thus, and *mired* with infamy,
I might have said no part of it is mine.
Shakspeare.

Shall thou and I sit round about some fountain
Looking all downwards to behold our cheeks,
How they are stained like meadows, yet not dry,
With *miry* slime left on them by a flood. *Id.*

I'm Ralph himself, your trusty squire,
Wh' has dragged your donship out o' the *mire*.
Hudibras.

Now plunged in *mire*, now by sharp brambles torn.
Roscommon.

I appeal to any man's reason, whether it be not better that there should be a distinction of land and sea, than that all should be *mire* and water.
More against Atheism.

All men who lived lazy lives, and died natural deaths, by sickness or by age, went into vast caves under ground, all dark and *miry*, full of noisome creatures, and there grovelled in endless stench and misery. *Temple.*

Deep, through a *miry* lane she picked her way,
Above her ancle rose the chalky clay.
Gay's Trivia.

So have I seen ill-coupled hounds
Drag different ways in *miry* grounds. *Swift.*

MIRECOURT, a little town of the department of the Vosges in France, and the chief place of a subprefecture, having an inferior court and a chamber of commerce. It is also a post town containin 5460 inhabitants. This town is situated in a fertile country, on the left bank of the Madon; it is generally badly built, but the suburbs are pleasant and well cultivated. It was in ancient times a place of some strength, with a good castle; but its fortifications were razed in 1670. The inhabitants carry on manufactures of lace, musical instruments of different sorts, as violins, bassviols, organs, &c., and leather; they also trade in corn, wine, brandy, sheep, wood, wrought iron goods, and the articles above mentioned. There is a public library containing 6000 volumes. It is twenty-one miles north-west of Epinal, twenty-seven east of Neufchateau, and 264 E. S. E. of Paris.

MIREVELT (Michael Jansen), portrait-painter, was the son of a goldsmith, and born at Delft in 1568. His father placed him with one of the Wierixes, of whom he learned to draw in crayons and to engrave. At the age of twelve he executed a print of the Samaritan woman; and not long after a figure of Judith holding Holofernes's head. These performances attracted the notice of Anthony Blockland, a historical painter of great note; and under his instructions Mirevelt greatly improved. He was very successful in painting history; but, finding portraits more profitable, he applied himself to portrait painting only. His reputation became so great that he exacted what price he pleased, never taking less than 150 florins a piece. His portraits are exceedingly numerous, and many of them were excellently engraved by William James Delft, a near relation, and a very skilful artist. He died in 1641.

MIREVELT (Peter), son of Michael, was born at Delft in 1596, and died in 1632. In his manner of design, style of coloring, and delicacy of pencil, he resembled his father; and by the best judges was accounted in no degree inferior to him.

MIRIAM, the sister of Aaron and Moses. It was owing to her that her mother was employed by Pharaoh's daughter as nurse to Moses. She put herself at the head of the women of Israel after their passage over the Red Sea, in order to sing the song which the men had sung before. She joined with her brother Aaron in murmuring against Moses, and was severely chastised for that action: for she became leprous, and continued separate from the rest without the camp for seven days. She died before her brothers, though in the same year, and was buried at the public expense.

MIRK'SOME, *adj.* Dan. *morck*, dark. Dark; obscure. See MURKY.

Through *mirksome* air her ready way she makes.
Faerie Queene.

MIROPOLJE, a town of European Russia, to the south of Moscow, in the government of Kursk. It contains seven churches, and 6300 inhabitants, who are employed more in agriculture than in manufactures. It is surrounded by a wall and ditch. Eighty-eight miles N. N. W. of Charkov.

MIRROR, *n. s.* Fr. *miroir*; Span. *mirar*; Lat. *miror*. An instrument valued for its bright, reflecting surface; whether of metal or glass: any thing which reflects objects; hence a pattern or example of any thing; an antitype.

If ony man is an heerer of the word, and not a doer, this schal be lickened to a man that biholdith the cheer of his birthe in a *myrrour*.
Wicliff. James i.

This *mirrour* eke that I have in min hond,
Hath swiche a might that men may in it see,
Whan ther shal falle ony adversity,
Unto your regne, or to yourself also.
Chaucer. Cant. Tales.

And in his waters, which your *mirror* make,
Behold your faces as the crystal bright. *Spenser.*

O goddess, heavenly bright,
Mirrour of grace and majesty divine.
Faerie Queene.

The works of nature are no less exact, than if she did both behold and study how to express some absolute shape or *mirror* always present before her.
Hooker.

How farest thou, *mirror* of all martial men?
Shakspeare.

That power which gave me eyes the world to view,
To view myself infused an inward light,
Whereby my soul, as by a *mirror* true,
Of her own form may take a perfect sight. *Davies.*

Less bright the moon,
But opposite in level west was set
His *mirror*, with full face borrowing her light
From him. *Milton's Paradise Lost.*

Mirroir of poets, *mirroir* of our age,
Which her whole face beholding on thy stage,
Pleased and displeased with her own faults, endures
A remedy like those whom musick cures. *Waller.*

By chance he spyed a *mirroir* while he spoke,
And gazing there beheld his altered look;
Wond'ring, he saw his features and his hue
So much were changed, that scarce himself he knew.
Dryden.

Mirroir of ancient faith in early youth. *Id.*

Late as I ranged the crystal wilds of air,
In the clear *mirroir* of thy ruling star,
I saw, alas! some dread event impend. *Pope.*

The night was dark, and the thick mist allowed
Nought to be seen save the artillery's flame,
Which arched the horizon like a fiery cloud,
And in the Danube's waters shone the same,
A *mirrored* hell! *Byron.*

MIRROR is also used for any polished body that forms the images of objects, by reflection of the rays of light. Mirrors are either plain, convex, or concave. The first reflect the rays of light in a direction exactly similar to that in which they fall upon them, and therefore represent bodies of their natural magnitude. The convex ones make the rays diverge much more than before reflection, and therefore greatly diminish the images of those objects which they show: while the concave ones, by collecting the rays into a focus, not only magnify the objects they show, but will burn very fiercely when exposed to the rays of the sun; and hence they are commonly known by the name of burning mirrors. In ancient times mirrors were made of some kind of metal; and from a passage in the Mosaic writings we learn that the mirrors used by the Jewish women were made of brass. The Jews certainly had been taught to use that kind of mirrors by the Egyptians; whence it is probable that brazen mirrors were the first kind used in the world, any metal, indeed, when well polished, will reflect very powerfully; but silver reflects the most, though it is too expensive a material for common use. Gold also is very powerful; and metals, or even wood gilded and polished, will act very powerfully as burning mirrors Even polished ivory, or straw nicely plaited together, will form mirrors capable of burning, if large. Since the invention of glass, and the application of quicksilver to it, became generally known, it has been universally employed for those plain mirrors used as ornaments to houses; but in making reflecting telescopes they have been found much inferior to metallic ones. It does not appear that the same superiority belongs to the metalline burning mirrors, considered merely as burning glasses; since the mirror with which Mr. Macquer melted platina, though only twenty-two inches diameter, and which was made of quicksilvered glass, produced much greater effects than M. Villette's metalline speculum, which considerably exceeded it in size. It is very probable, however, that this mirror of M. Villette's was by no means so well polished as it ought to have been; as the art of preparing the metal for taking the finest polish has but lately been discovered and published in the Philosophical Transactions by Mr. Mudge. See OPTICS and GLASS.

MIRTH, *n. s.*, MIRTH'FUL, *adj.*, MIRTH'LESS. Sax. myrðe. Merriment; hilarity; laughter: mirthful, cheerful; abounding in mirth or gaiety: mirthless, joyless; cheerless.

What then can move her, if nor *mirth*, nor mone
She is no woman, but a senseless stone. *Spenser.*

To give a kingdom for a *mirth*, to sit,
And keep the turn of tippling with a slave.
Shakspeare.

His eye begets occasion for his wit;
For every object that the one doth catch,
The other turns to a *mirth*-moving jest. *Id.*

No simple word,
That shall be uttered at our *mirthful* board,
Shall make us sad next morning. *Ben Jonson.*

Most of the appearing *mirth* in the world is not *mirth* but art: the wounded spirit is not seen, but walks under a disguise. *South.*

The feast was served; the bowl was crowned;
To the king's pleasure went the *mirthful* round.
Prior.

With genial joy to warm the soul,
Bright Helen mixed a *mirth* inspiring bowl.
Pope.

MIRZAPORE, a town of the province of Allahabad, Hindostan, is situated at the foot of a range of hills, on the south bank of the river Ganges, and in the district of Chunar. It is a flourishing trading town; the chief mart for silk and cotton between the British and Mahratta territories. It has also a manufacture of carpets, and iron works. The opulent merchants and indigo planters have handsome stone houses, intermixed with Hindoo temples, and flights of stone stairs leading to the river. Long. 83° 35 E., lat. 25° 10′ N.

MIRZAPORE, a town of Hindostan, province of Berar, formerly the capital of the district of Corair, belonging to the Chohan rajah, a tributary of the Mahrattas. There are several small places of the same name in India.

MISACCEPTA'TION, *n. s.* Of Fr. *mis*, and Teut. *mes*, a prefix denoting failure, deprivation, or deviation, in all the Gothic dialects, and acceptation. The taking an expression in a wrong sense.

The apostle fears none of the currish oblatrations; but, contemning all impotent *misacceptations*, calls them what he finds them, a froward generation. *Bp. Hall.*

MISADVENTURE, *n. s.* } Fr. *mesaventure;* MISADVEN'TURED, *adj.* } mis and adventure. Mischance; misfortune; ill luck: misadventured is unfortunate.

Your looks are pale and wild, and do import
Some *misadventure.* *Shakspeare. Romeo and Juliet.*
From forth the fatal loins of these two foes,
A pair of starcrost lovers take their life;
Whose *misadventured* piteous overthrows
Do with their death bury their parents' strife. *Shakspeare.*

When a commander, either upon necessity or *misadventure*, falleth into danger, it much advanceth both his reputation, and enterprise, if bravely he behaveth himself. *Hayward.*

The body consisted, after all the losses and *misadventures*, of no less than six thousand foot. *Clarendon.*

Distinguish betwixt *misadventure* and design. *L'Estrange.*

The trouble of a *misadventure* now and then, that reaches not his innocence or reputation, may not be an ill way to teach him more caution. *Locke on Education.*

MISAIM'ED, *adj.* Mis and aim. Not aimed rightly.

The idle stroke enforcing furious way,
Missing the mark of his *misaimed* sight,
Did fall to ground. *Faerie Queene.*

MIS'ANTHROPE, *n. s.* } Fr. *misanthrope;* MISAN'THROPOS, } Gr. *μισανθρωπος,* MISAN'THROPY. } of *μισος*, hatred, and *ανθρωπος*, man. A hater of mankind: misanthropy is hatred of mankind.

I am *misanthrophos*, and hate mankind. *Shakspeare.*

Was it heresy, or phrensy, or blasphemy, or all these, in the paternians of old, revived of late times, by Postellus at Paris, that man's lower parts were of a worse author? Away with that mad *misanthropy:* there is no inch of this living pile, which doth not bewray steps of an all-wise and holy omnipotence. *Bp Hall.*

Alas, poor dean! his only scope
Was to be held a *misanthrope;*
This into general odium drew him. *Swift.*

MISAPPLICA'TION, *n. s.* } Mis and apply. MISAPPLY', *v. a.* } To apply wrongfully, or to an improper purpose.

Virtue itself turns vice, being *misapplied*,
And vice sometime by action's dignified. *Shakspeare.*

The holy treasure was to be reserved, and issued for holy uses, and not *misapplied* to any other ends. *Howel.*

The indistinction of many in the community of name, or the *misapplication* of the act of one unto another, hath made some doubt thereof. *Browne's Vulgar Errours.*

He that knows that whiteness is the name of that color he has observed in snow, will not *misapply* that word as long as he retains that idea. *Locke.*

It is our duty to be provident for the future, and to guard against whatever may lead us into *misapplications* of it. *Rogers.*

The vigilance of those who preside over these charities is so exemplary, that persons disposed to do good can entertain no suspicions of the *misapplication* of their bounty. *Atterbury.*

MISAPPREHEND', *v. a.* } Mis and appre- MISAPPREHEN'SION. } hend. Mistake; misinterpretation.

It is a degree of knowledge to be acquainted with the causes of our ignorance: what we have to say under this head, will equally concern our *misapprehensions* and errors. *Glanville.*

That your reasonings may lose none of their force by my *misapprehending* or misrepresenting them, I shall give the reader your arguments. *Locke.*

MISARRANGE'MENT, *n. s.* Mis and arrangement. Wrong arrangement, if such there be; but the word cannot be well supported.

Here glittering turrets rise, upbearing high
(Fantastic *misarrangement!*) on the roof
Large growth of what may seem the sparkling trees
And shrubs of fairy land. *Cowper.*

MISASCRIBE', *v. v.* Mis and ascribe. To ascribe falsely.

That may be *misascribed* to art which is the bare production of nature. *Boyle.*

MISASSIGN', *v. a.* Mis and assign. To assign erroneously.

We have not *misassigned* the cause of this phenomenon. *Boyle.*

MISBECOME', *v. a.* & *v. n.* Mis and become. Not to become; to be unseemly or unsuitable.

Either she has a possibility in that which I think impossible, or else impossible loves need not *misbecome* me. *Sidney.*

What to the dauphin from England?
—Scorn and defiance, slight regard, contempt,
And any thing that may not *misbecome*
The mighty sender. *Shakspeare. Henry V.*

That boldness which lads get amongst play-fellows, has such a mixture of rudeness and ill turned confidence, that those *misbecoming* and disingenuous ways of shifting in the world must be unlearned to make way for better principles. *Locke.*

Portius, thou may'st rely upon my conduct;
Thy father will not act what *misbecomes* him. *Addison.*

MISBEGOT, *adj.* } Beget or begotten with MISBEGOT'TEN. } mis. Unlawfully or irregularly begotten.

Contaminated, base,
And *misbegotten* blood, I spill of thine. *Shakspeare.*
Your words have taken such pains, as if they laboured
To bring man-slaughter into form, set quarrelling
Upon the head of valor; which, indeed,
Is valour *misbegot*, and came into the world
When sects and factions were but newly born. *Id.*
The *misbegotten* infant grows,
And, ripe for birth, distends with deadly throes
The swelling rind, with unavailing strife,
To leave the wooden womb, and pushes into life. *Dryden.*

Down, immediately, should go fools from the high places where *misbegotten* chance has perked them up, and through life should they skulk, ever haunted by their native insignificance, as the body marches accompanied by its shadow. *Burns.*

MISBEHAVE', *v. n.* } Mis and behave. To MISBEHAVED', *adj.* } act ill or improperly: untaught; ill bred.

Happiness courts thee in her best array;
But, like a *misbehaved* and sullen wench,
Thou pout'st upon thy fortune and thy love. *Shakspeare.*

The *misbehaviour* of particular persons does not at all affect their cause, since a man may act laudably in some respects, who does not so in others.
Addison's Freeholder.

MISCAL', *v. a.* Mis and call. To name improperly.

My heart will sigh when I *miscal* it so.
Shakspeare.

The third act, which connects propositions and deduceth conclusions from them, the schools call discourse; and we shall not *miscal* it if we name it reason. *Glanville's Scepsis.*

What you *miscal* their folly is their care.
Dryden.

MISCA'LCULATE, *v. a.* Mis and calculate. To reckon wrong.

Say, did I not *miscalculate* thy power,
Which, though o'ergrown it seems,
Is yet so small. *Shakspeare.*

After all the care I have taken, there may be, in such a multitude of passages, several misquoted, misinterpreted, and *miscalculated.*
Arbuthnot on Coins

MISCA'RRY, *v. n.* } Mis and carry. To
MISCAR'RIAGE, *n. s.* } fail; not to produce the intended event; not to succeed : miscarriage is, failure; ill conduct; accident.

Give them a *miscarrying* womb and dry breasts.
Hos. ix. 14.

Have you not heard of Frederick, the great soldier, who *miscarried* at sea? *Shakspeare.*

Is it concluded he shall be protector?
—It is determined, not concluded yet:
But so it must be if the king *miscarry.* *Id.*

Resolutions of reforming do not always satisfy justice, nor prevent vengeance for former *miscarriages.*
King Charles.

There must be *miscarriages* and abortions; for there died many women with child. *Graunt.*

It (charity) covereth all things, studiously conniving at real defects, and concealing assured *miscarriages*: how much more not divulging imaginary or false scandal. *Barrow.*

When a counsellor, to save himself,
Would lay *miscarriages* upon his prince,
Exposing him to public rage and hate,—
O, 'tis an act as infamously base,
As, should a common soldier sculk behind
And thrust his general in the front of war.
Dryden.

If the neglect or abuse of the liberty he had, to examine what would really make for his happiness, misleads him, the *miscarriages* that follow on it must be imputed to his own election. *Locke.*

So many politick conceptions so elaborately formed and wrought, and grown at length ripe for a delivery, do yet, in the issue, *miscarry* and prove abortive.
South's Sermons.

Your cures aloud you tell,
But wisely your *miscarriages* conceal.
Garth.

I could mention some projects which I have brought to maturity, and others which have *miscarried.*
Addison's Guardian.

A great part of that time which the inhabitants of the former earth had to spare, and whereof they made so ill use, was now employed in digging and plowing; and the excess of fertility which contributed so much to their *miscarriages,* was retracted and cut off.
Woodward's Natural History.

How, alas! will he appear in that awful day, when even the failings and *miscarriages* of the righteous shall not be concealed, though the mercy of God be magnified in their pardon. *Rogers.*

His wife *miscarried*; but the abortion proved a female fœtus. *Pope and Arbuthnot.*

You have proved yourself more tender of another's embrios, than the fondest mothers are of their own; for you have preserved every thing that I *miscarried* of. *Pope.*

No wonder that this expedient should so often *miscarry,* which requires so much art and genius to arrive at any perfection in it. *Swift.*

MISCA'ST, *v. a.* Mis and cast. To take a wrong account of.

Men *miscast* their days: for in their age they deduce the account not from the day of their birth, but the year of our Lord wherein they were born.
Browne's Vulgar Errours.

MISCELLANE', *n. s.* } Lat. *miscellaneus.*
MISCELLA'NEOUS, *adj.* } Any thing mixed;
MISCEL'LANY, *n. s.* } particularly mixed corn; miscellaneous is, mingled; composed of various kinds or ingredients: miscellany, a compound; a mass of various kinds.

It is thought to be of use to make some *miscellane* in corn; as if you sow a few beans with wheat, your wheat will be the better. *Bacon's Natural History.*

The power of Spain consisteth in a veteran army, compounded of *miscellany* forces of all nations.
Bacon.

Being *miscellaneous* in many things, he is to be received with suspicion; for such as amass all relations must err in some, and without offence be unbelieved in many. *Brown.*

And what the people but a herd confused,
A *miscellaneous* rabble, who extol
Things vulgar and well weighed scarce worth the praise? *Milton's Paradise Lost.*

I acquit myself of the presumption of having lent my name to recommend miscellanies or works of other men. *Pope.*

When they have joined their pericranies,
Out skips a book of *miscellanies.* *Swift.*

MISCHANCE', *n. s.* Mis and chance. Ill luck; ill fortune; misfortune; mishap.

The lady Cecropia sent him to excuse the *mischance* of her beasts ranging in that dangerous sort.
Sidney.

Sleep rock thy brain,
And never come *mischance* between us twain.
Shakspeare.

Extreme dealing had driven her to put herself with a great lady, by which occasion she had stumbled upon such *mischances* as were little for the honour of her family. *Sidney.*

Nothing can be a reasonable ground of despising a man but some fault chargeable upon him; and nothing can be a fault that is not naturally in a man's power to prevent; otherwise it is a man's unhappiness, his *mischance* or calamity, but not his fault.
South.

I, for their thoughtless, careless sakes,
Would here propone defences,
Their donsie tricks, their black mistakes,
Their failings and *mischances.* *Burns*

MIS'CHIEF, *n. s.* & *v. a.* } Old F. *meschef,*
MIS'CHIEF-MAKER, *n. s.* } or *mis-acheivance.*
MIS'CHIEF-MAKING, *adj.* } Harm; hurt;
MIS'CHIEVOUS, } misdeed; any
MIS'CHIEVOUSLY, *adv.* } thing ill done, ill-
MIS'CHIEVOUSNESS, *n. s.* } intentioned, or vexatious: as a verb to injure, harm (obsolete). The derivatives follow these senses.

Thy tongue deviseth *mischiefs.* *Psal.* lii. 2

The law in that case punisheth the thought; for better is a *mischief* than an inconvenience.
Spenser on Ireland.

These mad *mischiefs*
Would dare a woman.
Beaumont and Fletcher.

Come you murthering ministers!
Wherever in your sightless substances
You wait on nature's *mischief*.
Shakspeare. Macbeth.

Purely to seek God's honour, and in all our actions to regard it as our principal aim, greatly disparageth all worldly glory as vain, transitory, *mischievous*.
Barrow.

Was I cause of *mischief*, or the man,
Whose lawless lust the fatal war began?
Dryden.

I'm but a half-strained villain yet;
But mongrel *mischievous*. *Id.*

Nor was the cruel destiny content
To sweep at once her life and beauty too;
But like a hardened felon took a pride
To work so *mischievously* slow,
And plundered first, and then destroyed.
Id.

If the greatest inward heat be not sweetened by meekness, or not governed by prudence, can it bring to our souls any benefit? rather it *mischiefs* them.
Spratt's Sermons.

This false, wily, doubling disposition is intolerably *mischievous* to society. *South's Sermons.*

Compare the harmlessness, the tenderness, the modesty, and the ingenuous pliableness, which is in youth, with the *mischievousness*, the slyness, the craft, the impudence, the falsehood, and the confirmed obstinacy found in an aged, long-practised sinner.
Id.

Come not thou with *mischief-making* beauty,
To interpose between us, look not on him. *Rowe.*

He had corrupted or deluded most of his servants, telling them that their master was run mad; that he had disinherited his heir, and was going to settle his estate upon a parish boy; that if he did not look after their master he would do some very *mischievous* thing. *Arbuthnot's History of John Bull.*

States call in foreigners to assist them against a common enemy; but the *mischief* was, these allies would never allow that the common enemy was subdued. *Swift.*

To smile at a jest that plants a thorn in another's breast, is to become a principal in the *mischief*.
Sheridan.

MISCHNA, or MISNA, from שנה, iteravit, i.e. he repeated, the first part of the Jewish Talmud. The Mischna contains the text; and the Gemara, which is the second part of the Talmud, contains the commentaries. See GEMARA. The Mischna consists of various traditions of the Jews, and of explanations of several passages of Scripture: these traditions, serving as an explication of the written law, and supplement to it, are said to have been delivered to Moses during his abode on the Mount; which he afterwards communicated to Aaron, Eleazar, and Joshua. By these they were transmitted to the seventy elders, by them to the prophets, who communicated them to the men of the great sanhedrim, from whom the wise men of Jerusalem and Babylon received them. According to Prideaux, they passed from Jeremiah to Baruch, from him to Ezra, and from Ezra to the men of the great synagogue, the last of whom was Simon the Just; who delivered them to Antigonus of Socho: and from him they came down in regular succession to Simeon, who took our Saviour in his arms; to Gamaliel, by whom Paul was educated; and last of all to Rabbi Judah the Holy, who committed them to writing in the Mischna. But Dr. Prideaux, rejecting this Jewish fiction, observes, that after the death of Simeon the Just, about A. A. C. 299, the Mischnical doctors arose, who, by their comments and conclusions, added to the number of those traditions which had been received by Ezra and the men of the great synagogue; so that towards the middle of the second century, under Antoninus Pius, it was found necessary to commit these traditions to writing; especially as their country had considerably suffered under Adrian, and many of their schools had been dissolved, and their learned men cut off; and therefore the usual method of preserving their traditions had failed. Rabbi Judah on this occasion being rector of the school at Tiberias, and president of the sanhedrim in that place, undertook the work, and compiled it in six books, each consisting of several tracts, which altogether make up the number of sixty-three. Prid. Connect. vol. ii. p. 468, &c. ed. 9. This learned author computes, that the Mischna was composed about A.D. 150; but Dr. Lightfoot says, that Rabbi Judah compiled the Mischna about A.D. 190, in the end of the reign of Commodus; or, as some compute, A. D. 220. Dr. Lardner is of opinion, that this work could not have been finished before the year 190, or later. Collection of Jewish and Heathen Testimonies, &c. vol. i. p. 178. Thus the book called the Mischna was formed; a book which the Jews have generally received with the greatest veneration. The original has been published with a Latin translation by Surenhusius, with notes of his own, and others from the learned Maimonides, &c., in 6 vols. fol. Amsterdam A. D. 1698—1703. See TALMUD. It is written in a much purer style, and is not nearly so full of dreams and visions as the Gemara.

MIS'CIBLE, *adj.* Lat. *misceo.* Possible to be mingled.

Acid spirits are subtile liquors which come over in distillations, not inflammable, *miscible* with water.
Arbuthnot.

MISCITA'TION, *n. s.* Mis and citation. Unfair or false quotation.

Being charged with *miscitation* and unfair dealing, it was requisite to say something; honesty is a tender point. *Collier.*

MISCLAIM', *n. s.* Mis and claim. Mistaken claim.

Error, *misclaim*, and forgetfulness, become suitors for some remission of extreme rigour. *Bacon.*

MISCOMPUTA'TION, *n. s.* Mis and computation. False reckoning.

It was a general misfortune and *miscomputation* of that time, that the party had so good an opinion of their own reputation and interest. *Clarendon.*

MISCONCEIT', *n. s.*
MISCONCEIVE', *v. a.*
MISCONCEP'TION, *n. s.*
Mis and conceit, and conception. False opinion, or notion: to misconceive is to misjudge; have a false notion of.

Nor let false whispers, breeding hidden fears,
Break gentle sleep with *misconceived* doubt.
Spenser.

Our endeavour is not so much to overthrow them with whom we contend, as to yield them just and reasonable causes of those things, which, for want of due consideration heretofore, they *misconceived*. *Hooker.*

The other which instead of it we are required to accept is only by error and *misconceit* named the ordinance of Jesus Christ; no one proof being as yet brought forth, whereby it may clearly appear to be so in very deed. *Id.*

Misconceived Joan of Arc hath been
A virgin from her tender infancy.
Shakspeare. Henry VI.

It cannot be that our knowledge should be other than an heap of *misconception* and error. *Glanville.*

Great errors and dangers result out of *misconception* of the names of things.
Harvey on Consumption.

It will be a great satisfaction to see those pieces of most ancient history, which have been chiefly preserved in scripture, confirmed anew and freed from those *misconceptions* or misrepresentations which made them sit uneasy upon the spirits even of the best men. *Burnet's Theory of the Earth.*

MISCON'DUCT, *n. s.* Mis and conduct. Ill behaviour; ill management.

They are industriously proclaimed and aggravated by such as are guilty or innocent of the same slips or *misconducts* in their own behaviour. *Addison.*

It highly concerned them to reflect, how great obligations both the memory of their past *misconduct*, and their present advantages, laid on them, to walk with care and circumspection. *Roger's Sermons.*

MISCONJEC'TURE, *n. s.* Mis and conjecture. A wrong guess.

I hope they will plausibly receive our attempts, or candidly correct our *misconjectures*. *Browne.*

MISCON'STRUE, *v. a.* } Mis and construe.
MISCONSTRUC'TION, *n. s.* } To interpret wrong: wrong interpretation.

That which, by right exposition, buildeth up Christian faith, being *misconstrued* breedeth error; between true and false construction the difference reason must shew. *Hooker.*

We would have had you heard
The manner and the purpose of his treasons;
That you might well have signified the same
Unto the citizens, who, haply, may
Misconstrue us in him. *Shakspeare. Richard III.*

It pleased the king, his master, very lately
To strike at me upon his *misconstruction*,
When he conjunct, and flattering his displeasure,
Tript me behind. *Id. King Lear.*

Many of the unbelieving Israelites would have *misconstrued* this story of mankind. *Raleigh.*

Others conceive the literal acceptation to be a *misconstruction* of the symbolical expression.
Browne.

Those words were very weakly inserted where they are so liable to *misconstruction*. *Stillingfleet.*

Do not, great Sir, *misconstrue* his intent,
Nor call rebellion what was prudent care,
To guard himself by necessary war. *Dryden.*

A virtuous emperor was much afflicted to find his actions *misconstrued* and defamed by a party.
Addison.

MISCOUN'SEL, *v. a.* Mis and counsel. To advise wrong.

Every thing that is begun with reason
Will come by ready means unto his end,
But things *miscounselled* must needs miswend.
Spenser.

MIS'CREANCE, *n. s.* } Fr. *mescreance*, or
MIS'CREANCY, } *mescroiance*. Unbe-
MIS'CREANT. } lief; false faith; adherence to a false religion: a miscreant is strictly one that holds a false faith; hence a bad man of any kind; a wretch.

If thou wilt renounce thy *miscreance*,
And my true liegeman yield thyself for ay,
Life will I grant thee for thy valiance.
Spenser.

Their prophets justly condemned them as an adulterous seed, and a wicked generation of *miscreants*, which had forsaken the living God. *Hooker.*

Now, by Apollo king,
Thou swear'st thy gods in vain.
—O vassal, *miscreant*.
Shakspeare. King Lear.

How unnatural is the villainy of those *miscreants*, that can be content to be actors in capital wrongs offered to sovereign authority. *Bp. Hall.*

The more usual causes of deprivation are murder, man-slaughter, heresy, *miscreancy*, atheism, simony.
Ayliffe.

If extraordinary lenity proves ineffectual, those *miscreants* ought to be made sensible that our constitution is armed with force.
Addison's Freeholder.

MISCREATE', *adj.* } Mis and create. Pro-
MISCREA'TED. } duced unnaturally or illegitimately; made as by a blunder.

Then made he head against his enemies,
And Ymner slew or Logis *miscreate*.
Faerie Queene.

Eftsoons he took that *miscreated* fair,
And that false other sprite, on whom he spread
A seeming body of the subtile air. *Spenser.*

God forbid, my lord,
That you should fashion, wrest, or bow your reading;
With opening titles *miscreate*, whose right
Suits not in native colours with the truth.
Shakspeare.

MISDEED', *n. s.* Mis and deed. Evil action.

O God,
If thou wilt be avenged on my *misdeeds*,
Yet execute thy wrath on me alone. *Shakspeare.*
Evils which our own *misdeeds* have wrought.
Milton.

Chased from a throne, abandon'd, and exil'd
For foul *misdeeds* were punishments too mild.
Dryden.

MISDEEM', *v. a.* Mis and deem. To judge ill of; to mistake.

All unweeting an enchanter bad
His sense abus'd, and made him to *misdeem*,
My loyalty, not such as it did seem.
Faerie Queene.

Besides, were we unchangeable in will,
And of a wit that nothing could *misdeem*;
Equal to God whose wisdom shineth still
And never errs, we might ourselves esteem.
Davies.

MISDEMEAN', *v. a.* } Mis and demean.
MISDEME'ANOR, *n. s.* } To behave ill: misdemeanor is offence; ill behaviour; something less than an atrocious crime.

From frailty
And want of wisdom, you, that best should teach us,
Have *misdemeaned* yourself.
Shakspeare. Henry VIII.

The house of commons have only power to censure the members of their own house, in point of election or *misdemeanors*, in or towards that house. *Bacon.*

It is no real disgrace to the church merely to lose her privileges, but to forfeit them by her fault or *misdemeanor*. *South.*

These could never have touched the head, or stopped the source of these unhappy *misdemeanors*, for which the punishment was sent. *Woodward.*

MISDEVOTION, *n. s.* Mis and devotion. Mistaken piety.

A place, where *misdevotion* frames
A thousand prayers, to saints, whose very names
The church knew not, heaven knows not yet.
Donne.

MISDI'ET, *n. s.* Mis and diet. Improper food.

A dropsy through his flesh did flow,
Which by *misdiet* daily greater grew.
Faerie Queene.

MISDISTIN'GUISH, *v. a.* Mis and distinguish. To make wrong distinctions.

If we imagine a difference where there is none, because we distinguish where we should not, it may not be denied that we *misdistinguish*. *Hooker.*

MISDO', *v. a.* & *v. n.* } Mis and do. To do
MISDO'ER, *n. s.* } wrong; to commit;
MISDO'ING, *n. s.* } faults; a misdoer is, an offender; criminal: misdoing, offence; deviation from right.

Were they not contained in duty with a fear of law, which inflicteth sharp punishments to *misdoers*, no man should enjoy any thing. *Spenser on Ireland.*

Afford me place to show what recompence
T'wards thee I intend for what I have *misdone*.
Milton.

Try the erring soul
Not wilfully *misdoing*, but unaware
Misled. *Id. Paradise Regained.*

I have *misdone*, and I endure the smart,
Loth to acknowledge, but more loth to part.
Dryden.

The worst is, to think ourselves safe so long as we keep our injuries from the knowledge of men, and out of our own view, without any awe of that all-seeing eye that observes all our *misdoings*. *L'Estrange.*

MISDOUBT', *v. a.* & *n. s.* Mis and doubt. To suspect of deceit or danger: suspicion of crime or danger.

If she only *misdoubted* me, I were in heaven; for quickly I would bring sufficient assurance. *Sidney.*

The bird that hath been limed in a bush,
With trembling wings *misdoubteth* every bush
And I, the hapless male to one sweet bird,
Have now the fatal object in my eye,
Where my poor young was limed, was caught, and killed. *Shakspeare. Henry VI.*

York, steel thy fearful thoughts,
And change *misdoubt* to resolution.
Shakspeare.

To believe his wiles my truth can move,
Is to *misdoubt* my reason or my love. *Dryden.*

MISE, in law, is used in various senses: sometimes for costs or expenses; in which sense it is commonly used in entering of judgments in actions personal. It is also used for the issue to be tried on the grand assize; in which case, joining of the mise upon the mere right is putting in issue, between the tenant and demandant, Who has the best or clearest right?

MISE also signifies a tax or tallage, &c. An honorary gift, or customary present from the people of Wales to every new king or prince of Wales, anciently given in cattle, wine, and corn, but now in money, being £5000 or more, is denominated a mise: so was the usual tribute of 3000 merks paid by the inhabitants of the county palatine of Chester at the change of every owner of the said earldoms, for enjoying their liberties. At Chester they have a mise-book, wherein every town and village in the county is rated what to pay towards the mise. The 27 Hen. VII. c. 26 ordains that lords shall have all such mises and profits of their lands as they had in times past, &c.

MISE is sometimes also corruptly used for mease, in law French mees, a message; as a mise place, in some manors, such a message or tenement as answers the lord a heriot at the death of its owner.

MISEMPLOY', *v. a.* } Mis and employ.
MISEMPLOY'MENT, *n. s.* } To use to wrong purposes: improper application.

An improvident expense, and *misemployment* of their time and faculties. *Hale's Origin of Mankind.*

Their frugal father's gains they *misemploy*,
And turn to point and pearl, and every female toy.
Dryden.

Some, taking things upon trust, *misemploy* their powers by lazily enslaving their minds to the dictates of others. *Locke.*

That vain and foolish hope, which is *misemployed* on temporal objects, produces many sorrows. *Addison's Spectator.*

They grew dissolute and profane: and, by *misemploying* the advantages which God had thrown into their lap, provoked him to withdraw them. *Atterbury.*

MISENUM, or MISENUS, in ancient geography, a promontory, port, and town of Italy, in Campania, south-west of Baiæ, in the Sinus Puteolanus, on the north side. Here Augustus had a fleet, called Classis Misenensis, for guarding the Mare Inferum; as he had another at Ravenna for the Superum. On this peninsula a villa was built by Caius Marius, with a degree of elegance that gave great offence to the more austere among the Romans, who thought it ill suited to the character of so rough a soldier. Upon the same foundation Lucullus, the plunderer of the eastern world, erected an edifice, in comparison of which the former house was a cottage; but even his magnificence was eclipsed by the splendor of the palace which the emperors raised upon the same spot. To these proud abodes of heroes and monarchs, which have long been levelled to the ground, a few fishing huts, as Mr. Swinburn informs us, and a lonely public house, have succeeded; hither boatmen resort to tipple, perhaps on the identical site where the voluptuous masters of the world quaffed Chian and Falernian wines.

MI'SER, *n. s.* Lat. *miser*. An unhappy wretch; hence, particularly, a covetous wretch: one who in wealth is miserable for the fear of poverty.

Do not disdain to carry with you the woeful words

of a miser now despairing; neither be afraid to appear before her bearing the base title of the sender. *Sidney.*

Fair son of Mars, that seek with warlike spoil
And great atchievements, great yourself to make,
Vouchsafe to stay your steed for humble *miser's* sake. *Spenser.*

Decrepit *miser!* base ignoble wretch!
I am descended of a gentler blood. *Shakspeare.*

Though she be dearer to my soul than rest
To weary pilgrims, or to *misers* gold,
Rather than wrong Castalio I'd forget her. *Otway.*

No silver saints by dying *misers* giv'n,
Here bribed the rage of ill-requited heaven;
But such plain roofs as piety could raise,
And only vocal with the Maker's praise. *Pope.*

MIS'ERABLE, *adj.* } Fr. *miserable;* Lat. MIS'ERABLY, *adv.* } *miser.* Unhappy; MIS'ERY, *n. s.* } wretched; mean; sordid: miserably is, unhappily, calamitously; meanly: misery, is also used both for wretchedness, unhappiness, calamity, and in an obsolete sense for covetousness, avarice.

Miserable comforters are ye all. *Job.* xvi. 2.

As the love I bear you makes me thus invite you, so the same love makes me ashamed to bring you to a place where you shall be so, not spoken by ceremony but by truth, *miserably* entertained. *Sidney.*

O nation *miserable,*
With an untitled tyrant, bloody sceptered!
When shalt thou see thy wholesome days again? *Shakspeare.*

My heart is drowned with grief,
My body round engirt with *misery.* *Id.*

He looked upon things precious as they were
The common muck o' th' world: he covets less
Than *misery* itself would give. *Shakspeare. Coriolanus.*

When we our betters see bearing our woes
We scarely think our *miseries* our foes. *Shakspeare.*

He that hath pity on another man's sorrow, shall be free from it himself, and he that delighteth in, and scorneth the *misery* of another, shall one time or other fall into it himself. *Raleigh.*

In a fabrick of a forty thousand pounds charge, I wish thirty pounds laid out before in an exact model; for a little *misery* may easily breed some absurdity of greater charge. *Wotton.*

What hopes delude thee, *miserable* man? *Dryden.*

MISERERE (Latin, *have mercy*); the name of a celebrated church song, taken from the fifty-seventh psalm, beginning, in the Vulgate, *Miserere mei, Domine.* The *miserere* forms part of certain liturgies, and various great composers have taken it as a subject. The *miserere* of Allegri (q. v.) is particularly famous; and this alone, sung by the Papal choir, in the *capella Sistina,* in the Passion week, would repay the trouble of a visit to the "eternal city."

MISERERE is also the name given to pictures representing the dying Saviour. A terrible disease, produced by obstruction of the bowels, is also called by this name.

MISERICORDIA, in law, an arbitrary fine imposed on any person for an offence: this is called misericordia, because the amercement ought to be but small, and less than that required by magna charta. If a person be outrageously amersed in a court that is not of record, the writ called moderata misericordia lies for moderating the amercement according to the nature of the fault.

MISERICORDIA (mercy; in Greek, ἔλεος) was personified as a deity. She had a celebrated altar in the market-place of Athens, constituting an asylum. *Misericordias Domini* is the name given to the second Sunday after Easter, because the mass for this day begins with *Misericordias Domini cantabo in æternum.* *Misericorde* (French) was also the name of the dagger of the knights in the middle ages. Fauchet derives its name from its putting men out of pain when irrecoverably wounded, or from the sight of it causing the vanquished to cry out for mercy.

MISFASHION, *v. a.* Mis and fashion. To form wrong.

MISFORM, *v. a.* Mis and form. To put in an ill form.

His monstrous scalp down to his teeth it tore,
And that *misformed* shape misshaped more. *Spenser.*

MISFOR'TUNE, *n. s.* Mis and fortune. Calamity; ill luck; want of good fortune.

Fortune thus 'gan say, misery and *misfortune* is all one,
And of *misfortune,* fortune hath only the gift. *Sidney.*

MISFORTUNE, or chance, in law, is a deficiency of the will in committing an unlawful act; or by chance, and not by design. In such case the will does not co-operate with the deed; which, therefore, wants one main ingredient of a crime. See CRIME. For this, when it affects the life of another, see the article HOMICIDE. Here we need only observe that if any accidental mischief happens to follow from the performance of a lawful act, the party stands excused from all guilt: but if a man be doing any thing unlawful, and a consequence ensues which he did not foresee or intend, as the death of a man or the like, his want of foresight shall be no excuse; for being guilty of one offence, in doing antecedently what is in itself unlawful, he is criminally guilty of whatever consequence may follow the first misbehaviour.

MISGIVE', *v. a.* } Mis and give. To fill MISGIV'ING, *n. s.* } with doubt; deprive of confidence. Used with the reciprocal pronoun: misgiving is doubt; distrust.

As Henry's late presaging prophecy
Did glad my heart with hope of this young Richmond;
So doth my heart *misgive me* in these conflicts
What may befal him, to his harm or ours. *Shakspeare.*

Yet oft his heart divine of something ill,
Misgave him. *Milton.*

If a conscience thus qualified and informed, be not the measure by which a man may take a true estimate of his absolution, the sinner is left in the plunge of infinite doubts, suspicions, and *misgivings,* both as to the measures of his present duty, and the final issues of his future reward. *South.*

His heart *misgave him,* that these were so many meeting-houses; but, upon communicating his suspicions, I soon made him easy. *Addison's Freeholder.*

MISGOV'ERN, *v. a.* | Mis and govern.
MISGOV'ERNED, *adj.* | To govern ill; admi-
MISGOV'ERNANCE, *n. s.* | nister unfaithfully:
MISGOV'ERNMENT, *n. s.* | misgovernment is, rude; uncivilised: misgovernance, irregularity; synonymous with misgovernment, or ill administration of affairs.

Thy muse too long slumbereth in sorrowing
Lulled asleep through love's *misgovernance*.
Spenser.

Solyman charged him bitterly, that he had *misgoverned* the state, and inverted his treasures to his own use. *Knolles.*

Rude, *misgoverned* hands, from window tops,
Threw dust and rubbish on King Richard's head.
Shakspeare.

There is not chastity enough in language,
Without offence, to utter them: thus, pretty lady,
I am sorry for thy much *misgovernment*. *Id.*

Men lay the blame of those evils whereof they know not the ground, upon public *misgovernment*. *Raleigh's Essays.*

Men are miserable, if their education hath been so undisciplined as to leave them unfurnished of skill to spend their time; but most miserable, if such *misgovernment* and unskilfulness make them fall into vicious company. *Taylor.*

MISGUIDE', *v. a.* | Mis and guide. To
MISGUI'DANCE, *n. s.* | direct ill or wrong: misguidance, false direction.

The Nicene council fixed the equinox the twenty-first of March for the finding out of Easter: which has caused the *misguidance* from the sun which we lie under in respect of Easter, and the moveable feasts. *Holder on Time.*

Hunting after arguments to make good one side of a question, and wholly to neglect those which favor the other, is wilfully to *misguide* the understanding; and, is so far from giving truth its due value, that it wholly debases it. *Locke.*

Whosoever deceives a man makes him ruin himself; and by causing an error in the great guide of his actions, his judgment, he causes an error in his choice, the *misguidance* of which must naturally engage him to his destruction. *South.*

Misguided prince! no longer urge thy fate,
Nor tempt the hero to unequal war. *Prior.*

Of all the causes which conspire to blind
Man's erring judgment, and *misguide* the mind,
What the weak head with strongest bias rules
Is pride, the never-failing vice of fools. *Pope.*

MISHAP', *n. s.* Mis and hap. Ill chance or luck; calamity.

To tell you what miserable *mishaps* fell to the young prince of Macedon his cousin, I should too much fill your ears with strange horrours. *Sidney.*

Since we are thus far entered into the consideration of her *mishaps*, tell me, have there been any more such tempests wherein she hath thus wretchedly been wrecked? *Spenser.*

Rome's readiest champions, repose you here,
Secure from worldly chances and *mishaps*.
Shakspeare.

It cannot be
But that success attends him; if *mishap*,
Ere this he had returned, with fury driven,
By his avengers; since no place like this
Can fit his punishment, or your revenge. *Milton.*

If the worst of all *mishaps* hath fallen,
Speak; for he could not die unlike himself.
Denham.

MISINFER', *v. a.* Mis and infer. To infer wrong.

Nestorius teaching rightly, that God and man are distinct natures, did thereupon *misinfer*, that in Christ those natures can by no conjunction make one person. *Hooker.*

MISINFORM', *v. a.* | Mis and inform.
MISINFORMA'TION, *n. s.* | To deceive by false accounts: misinformation, false intelligence; false accounts.

Some belonged to a man of great dignity, and not as that wicked Simon had *misinformed*.
2 *Mac.* iii. 11.

By no means trust to your servants, who mislead you, or *misinform* you; the reproach will lie upon yourself. *Bacon.*

Let not such be discouraged as deserve well, by *misinformation* of others, perhaps out of envy or treachery. *Id.*

Bid her well beware,
Lest, by some fair appearing good surprised,
She dictate false; and *misinform* the will
To do what God expressly hath forbid. *Milton.*

The vengeance of God, and the indignation of men, will join forces against an insulting baseness, when backed with greatness, and set on by *misinformation*. *South's Sermons.*

MISINTER'PRET, *v. a.* Mis and interpret. To explain to a wrong sense, or wrong intention.

The gentle reader rests happy to hear the worthiest works *misinterpreted*, the clearest actions obscured, and the innocentest life traduced. *Ben Jonson.*

After all the care I have taken, there may be several passages misquoted and *misinterpreted*.
Arbuthnot on Coins.

MISJOIN', *v. a.* Mis and join. To join unfitly or improperly.

In reason's absence mimick fancy wakes
To imitate her; but *misjoining* shapes,
Wild work produces oft, and most in dreams;
Ill-matching words, and deeds, long past, or late.
Milton.

Luther, more mistaking what he read,
Misjoins the sacred body with the bread.
Dryden.

MISITRA, a town of Modern Greece, the capital of the Morea, renowned in the ancient history of Greece under its original names of LACEDÆMON and SPARTA. See these articles. It has an impregnable castle seated on a rock; several churches, one of them called Perileptos, said to be one of the most beautiful in the world; a superb Turkish mosque and hospital, with three Jewish synagogues; and two large suburbs. It is the see of a Greek archbishop; the residence of a bey, an aga, and a waywode; and contains about 12,000 inhabitants. It is seated on the Vasilipotamo, forty miles S. S. W. of Argos, forty E. N. E. of Navarin, sixty south of Corinth, ninety east of Lepanto, and ten south-west of Athens or Setines. It was taken by the Russians in 1770. Long. 22° 30′ E., lat. 37° 11′ N.

MISJUDGE', *v. n.* & *v. a.* Mis and judge. To form false opinions; judge ill: to mistake; judge ill of.

You *misjudge*;
You see through love, and that deludes your sight;
As, what is straight, seems crooked through the water. *Id.*

Where we *misjudge* the matter, a miscarriage draws pity after it; but, when we are transported by pride, our ruin lies at our own door. *L'Estrange.*

By allowing himself in what is innocent, he breeds offence to his weak and *misjudging* neighbour. *Atterbury.*

Insensate!
Too long *misjudging* have I thought thee wise,
But sure relentless folly steels thy breast. *Pope.*

MISKOLCZ, a considerable and well built town of Hungary, in the county of Borschod, of which it is the capital. It contains 13,600 inhabitants, the majority of whom are Maggars, or Hungarians proper; the rest are Slowacs, Russniacks, Walachians, Germans, Greeks, Jews, and gypsies. The greater number are Calvinists, who have one of their gymnasia or high schools here, as well as several elementary schools. The Catholics, Lutherans, and Greeks have their own churches; the Jews a synagogue; and the Minorites a monastery. There are no extensive manufacturing establishments. It is thirty-three miles west of Tokay.

MISLAY', *v. a.* } Mis and lay. To lay in MISLAYER', *n. s.* } a wrong place: one that puts in a wrong place.

The *mislayer* of a mere stone is to blame; but the unjust judge is the capital remover of landmarks, when he defineth amiss of lands. *Bacon.*

Mean time my worthy wife our arms *mislayed*,
And from beneath my head my sword conveyed. *Dryden.*

The fault is generally *mislaid* upon nature; and there is often a complaint of want of parts, when the fault lies in want of a due improvement. *Locke.*

If the butler be the tell-tale, *mislay* a spooon, so as he may never find it. *Swift's Rules to Servants.*

MISLEAD', *v. a.* } Preterite and participle MISLEAD'ER, *n. s.* } passive misled. Mis and lead. To guide a wrong way; to betray to mischief or mistake: one that leads to ill.

They have disclaimed and abandoned those heretical phantasies touching our Saviour, wherein by their *misleaders* they had been anciently plunged. *Brerewood on Languages.*

Take, oh take those lips away,
That so sweetly were forsworn;
And those eyes, the break of day,
Lights that do *mislead* the morn. *Shakspeare.*

When thou dost hear I am as I have been,
Approach me, and thou shalt be as thou wast,
The tutor and the feeder of my riots;
Till then I banish thee on pain of death,
As I have done the rest of my *misleaders*. *Id.*

Trust not servants who *mislead* or misinform you. *Bacon.*

Poor *misled* men: your states are yet worthy pity.
If you would hear, and change your savage minds,
Leave to be mad. *Ben Jonson's Catiline.*

O thievish night,
Why shouldest thou but for some felonious end,
In thy dark lanthorn thus close up the stars,
That nature hung in heaven, and filled their lamps
With everlasting oil, to give due light
To the *misled* and lonely traveller? *Milton.*

What can they teach and not *mislead*;
Ignorant of themselves, of God much more? *Id.*

The imagination, which is of simple perception, doth never of itself, and directly *mislead* us; yet it is the almost fatal means of our deception. *Glanville's Scepsis.*

Thou who hast taught me to forgive the ill,
And recompense, as friends, the good *misled*;
If mercy be a precept of thy will,
Return that mercy on thy servant's head. *Dryden.*

Whatever necessity determines to the pursuit o. real bliss, the same necessity establishes suspense, and scrutiny of each successive desire, whether the satisfaction of it does not interfere with our true happiness, and *mislead* us from it. *Locke.*

'Tis hard to say, if greater want of skill
Appear in writing or in judging ill;
But of the two, less dangerous is the offence
To tire our patience, than *mislead* our sense. *Pope.*

MISLIKE', *v. a.* & *n. s.* } Mis and like. MISLI'KER, *n. s.* } To disapprove; dislike: disapprobation; distaste: a misliker is one that disapproves.

Open flatterers of great men, privy *mislikers* of good men, fair speakers with smiling countenances. *Ascham.*

Himself stood director over them, with nodding or stamping, showing he did like or *mislike* those things he did not understand. *Sidney.*

Setting your scorns and your *mislikes* aside,
Tell me some reason, why the lady Grey
Should not become my wife. *Shakspeare. Henry VI.*

Tertullian was not deceived in the place; but Aquinas, who *misliked* this opinion, followed a worse. *Raleigh.*

Their angry gestures with *mislike* disclose,
How much his speech offends their noble ears. *Fairfax.*

Judge not the preacher, for he is thy judge:
If thou *mislike* him, thou conceiv'st him not. *Herbert.*

We have religion enough to *mislike* pleasures; not to overcome them. But if we be once conquerors over ourselves, and have devoted ourselves wholly to God, there can be nothing but heavenly mirth to the soul. *Bp. Hall.*

MIS'LEN, *n. s.* From MISCELLANE, which see. Mixed corn: as, wheat and rye.

They commonly sow those lands with wheat, *mislen*, and barley. *Mortimer's Husbandry.*

MIS'LE, *v. n.* From MIST. To rain in imperceptible drops, like a thick mist: properly mistle.

Ynough thou mourned hast,
Now ginnes to *mizzle*, hie we homeward fast. *Spenser.*

The very small drops of a *misling* rain descending through a freezing air, do each of them shoot into one of those figured icicles. *Grew's Cosmologia.*

In *misling* days when I my thresher heard,
With happy beer I to the barn repaired. *Gay's Pastorals.*

This cold precipitates the vapours either in dews, or, if the vapours more copiously ascend, they are condensed into *misling*, or into showers of small rain, falling in numerous, thick, small drops. *Derham's Physico-Theology.*

MISLIVE', *v. n.* Mis and live. To live ill.

Should not thilke God, that gave him that good,
Eke cherish his child if in his ways he stood,
For if he *mislive* in lewdness and lust,
Little boots all the wealth and the trust. *Spenser.*

MISMAN'AGE, *v. a.* } Mis and manage. MISMAN'AGEMENT, *n. s.* } To manage ill: ill management or conduct

The debates of princes' councils would be in danger to be *mismanaged*, since those who have a great stroke in them are not always perfectly knowing in the forms of syllogism. *Locke.*

It is *mismanagement* more than want of abilities, that men have reason to complain of in those that differ. *Id.*

3 C 2

The falls of fav'rites, projects of the great,
Of old *mismanagement*, taxations new,
All neither wholly false, nor wholly true. *Pope.*

MISMARK', *v. a.* Mis and mark. To mark with a wrong token.

Things are *mismarked* in contemplation and life for want of application or integrity. *Collier.*

MISMATCH', *v. a.* Mis and match. To match unsuitably.

What at my years forsaken! had I
Ugly, or old, *mismatched* to my desires
My natural defects had taught me
To set me down contented. *Southern.*

MISNAME', *v. a.* Mis and name. To call by the wrong name.

They make one man's fancies, or perhaps failings, confining laws to others, and convey them as such to their succeeders, who are bold to *misname* all unobsequiousness to their incogitancy, presumption. *Boyle on Colours.*

A MISNOMER, in law, a misnaming or mistaking a person's name. The Christian name of a person should always be perfect; but the law is not so strict in regard to surnames, a small mistake in which will be dispensed with to make good a contract, and support the act of the party. See PLEA TO INDICTMENT.

MISO, a substance resembling salt butter, and used as a substitute for it by the Japanese, prepared from a plant called daidsu, a species of dolichos. To make it they take a measure of mame, or the beans produced by the plant; after boiling them for a considerable time in water, and to a proper degree of softness, they beat or bray them into a softish pulse, incorporating with the mass a large quantity of salt, four measures in summer and three in winter. The less salt that is added, the substance is more palatable; but what it gains in point of taste it loses in durability. They then add to this mixture a certain proportion of rice, called koos; and, having formed the whole into a compost, remove it into a wooden vessel which had lately contained their common ale, named sacki. In two months it is fit for use. The koos gives it a grateful taste; and the preparing of it, like the palenta of the Germans, requires the skilful hand of an experienced master. For this reason there are people who make it their sole business to prepare the koos, and who sell it ready made for making miso: a substance which cannot fail to be greatly valued in those countries where butter from the milk of animals is unknown.

MISOBSERVE', *v. a.* Mis and observe. Not to observe accurately.

They understand it as early as they do language; and, if I *misobserve* not, they love to be treated as rational creatures sooner than is imagined. *Locke.*

MISOR'DER, *v. a.* & *n. s.* } Mis and order.
MISOR'DERLY, *adj.* } To conduct ill: irregularity; disorderly proceedings: misorderly is irregular; unlawful.

If the child miss either in forgetting a word or *misordering* the sentence, I would not have the master frown. *Ascham.*

His over-much fearing of you drives him to seek some *misorderly* shift, to be helped by some other book, or to be prompted by some other scholar. *Ascham's Schoolmaster.*

The time *misordered* doth in common sense
Crowd us, and crush us to this monstrous form,
To hold our safety up. *Shakspeare. Henry IV.*

When news was brought to Richard the Second, that his uncles, who sought to reform the *misorders* of his counsellors, were assembled in a wood near unto the court, he merrily demanded of one Sir Hugh a Linne, who had been a good military man, but was then somewhat distraught of his wits, what he would advise him to do? Issue out, quoth Sir Hugh, and slay them every mother's son; and when thou hast so done thou hast killed all the faithful friends thou hast in England. *Camden.*

MISPEL', *v. a.* Mis and spell. To spell wrong.

She became a profest enemy to the arts and sciences, and scarce ever wrote a letter to him without wilfully *mispelling* his name. *Spectator.*

MISPEND', *v. a.* } Preterite and part. pas-
MISPEND'ER, *n. s.* } sive mispent. Mis and spend. To spend ill; waste; consume to no purpose: mispender, one who spends prodigally.

What a deal of cold business doth a man *mispend* the better part of life in! In scattering compliments, tendering visits, gathering and venting news. *Ben Jonson's Discovery.*

First guilty conscience doth the mirrour bring,
Then sharp remorse shoots out her angry sting;
And anxious thoughts, within themselves at strife,
Upbraid the long *mispent* luxurious life. *Dryden.*

Now let the arched knife their thirsty limbs
Dissever, for the genial moisture due
To apples, otherwise *mispends* itself
In barren twigs. *Phillips.*

I suspect the excellency of those men's parts who are dissolute, and careless *mispenders* of their time. *Norris.*

He who has lived with the greatest care will find, upon a review of his time, that he has something to redeem; but he who has *mispent* much has still a greater concern. *Rogers.*

I this writer's want of sense arraign,
Treat all his empty pages with disdain,
And think a grave reply *mispent* and vain. *Blackmore.*

Let him now endeavour to redeem what he hath *mispent* by employing more of that leisure in this duty for the future. *Duty of Man.*

O man! while in thy early years,
How prodigal of time!
Mispending all thy precious hours,
Thy glorious youthful prime! *Burns.*

MISPERSUA'SION, *n. s.* Mis and persuasion. Wrong notion; false opinion.

Some *mispersuasions* concerning the divine attributes tend to the corrupting men's manners. *Decay of Piety.*

MISPLACE', *v. a.* Mis and place. To put in a wrong place.

I'll have this crown of mine cut from my shoulders,
Before I'll see the crown so foul *misplaced*. *Shakspeare.*

What little arts govern the world! we need not
An armed enemy or corrupted friend,
When service but *misplaced*, or love mistaken,
Performs the work. *Denham's Sophy.*

Is a man betrayed by such agents as he employs? He *misplaced* his confidence, took hypocrisy for fidelity, and so relied upon the services of a pack of villains. *South.*

Shall we repine at a little *misplaced* charity, we who could no way foresee the effect? *Atterbury.*

MISPRISE', *v. a.* } Either from Fr. *mesprendre*, mistake, or *mepriser*, undervalue, disdain. To mistake, or slight; despise: the noun follows one or other of these senses; but both words are obsolete.
MISPRIS'ION, *n. s.* }

You spend your passion on a *misprised* mood;
I am not guilty of Lysander's blood. *Shakspeare.*

Pluck indignation on thy head;
By the *misprising* of a maid, too virtuous
For the contempt of empire. *Id.*

Thou hast mistaken quite,
And laid thy love-juice on some true love's sight;
Of thy *misprision* must perforce ensue
Some true love turned, and not a false turned true. *Id.*

To vindicate our religion from such *misprisions*, and that we may be engaged to prise and cherish it, I shall endeavour to declare that Christian faith doth worthily deserve all the commendations and the advantages granted thereto. *Barrow.*

We feel such or such a sentiment within us, and herein is no cheat or *misprision*; it is truly so, and our sense concludes nothing of its rise. *Glanville's Scepsis.*

MISPRISIONS, from the old French, mespris, a neglect or contempt, are, in the English law, generally understood to be all such high offences as are under the degree of capital, but nearly bordering thereon; and a misprision is contained in every treason and felony whatsoever; and, if the king please, the offender may be proceeded against for the misprision only. Upon this principle, while the jurisdiction of the star-chamber subsisted, it was held that the king might remit a prosecution for treason, and cause the delinquent to be censured in that court, merely for a high misdemeanor; as happened in the case of Roger, earl of Rutland, in 43 Eliz., who was concerned in the earl of Essex's rebellion. Misprisions are generally divided into two sorts, viz. negative, which consist in the concealment of something which ought to be revealed; and positive, which consist in the commission of something which ought not to be done.

MISPRISIONS, NEGATIVE, are either misprision of treason or of felony.

MISPRISION OF FELONY is the concealment of a felony which a man knows, but never assented to; for, if he assented, this makes him either principal or accessory. And the punishment of this, in a public officer, by stat. Westm. 1. 3 Ed. I. c. 9, is imprisonment for a year and a day: in a common person, imprisonment for a less discretionary time; and in both, fine and ransom at the king's pleasure; which pleasure of the king must be observed, once for all, not to signify any extrajudicial will of the sovereign, but such as is declared by his representatives, the judges in his courts of justice, voluntas regis in curia, non in camera.

MISPRISION OF TREASON consists in the bare knowledge and concealment of treason, without any degree of assent thereto: for any assent makes the party a principal traitor; as indeed the concealment, which was construed aiding and abetting, did at the common law; in like manner, as the knowledge of a plot against the state, and not revealing it, was a capital crime at Florence, and other states of Italy. But it is enacted, by stat. 1 and 2 P. & M. c. 10, that a bare concealment of treason shall be only held a misprision. This concealment becomes criminal if the party apprised of the treason does not, as soon as conveniently may be, reveal it to some judge of assize or justice of the peace. But if there be any probable circumstances of assent, as if one goes to a treasonable meeting, knowing beforehand that a conspiracy is intended against the king; or being in such company once by accident, and, having heard such treasonable conspiracy, meets the same company again, and hears more of it, but conceals it, this is an implied assent in law, and makes the concealer guilty of actual high treason.

MISPRISIONS, POSITIVE, are generally denominated contempt or high misdemeanors; of which the principal is the mal-administration of such high offices as are in public trust and employment. This is usually punished by the method of parliamentary impeachment; wherein such penalties, short of death, are inflicted, as to the wisdom of the house of peers shall seem proper; consisting usually of banishment, imprisonment, fines, or perpetual disability. Hither also may be referred the offence of embezzling the public money, called among the Romans peculatus; which the Julian law punished with death in a magistrate, and with deportation, or banishment, in a private person. In the English law it is not capital, but subjects the committer of it to a discretionary fine and imprisonment. Other misprisions are, in general, such contempts of the executive magistrate as demonstrate themselves by some arrogant and undutiful behaviour towards the king and government. For a detail of which see *Blackstone's Commentaries*, iv. 12.

MISPROUD', *adj.* Mis and proud. Viciously proud. Obsolete.

Now I fall thy touch commixtures melt,
Impairing Henry, strengthening *misproud* York. *Shakspeare.*

MISQUOTE', *v. a.* Mis and quote. To quote falsely.

Look how we can, or sad, or merrily,
Interpretation will *misquote* our looks. *Shakspeare.*

After all the care I have taken, there may be several passages *misquoted*. *Arbuthnot on Coins.*

MISRECITE', *v. a.* Mis and recite. To recite not according to the truth.

He *misrecites* the argument, and denies the consequence, which is clear. *Bramhall against Hobbes.*

MISREC'KON, *v. a.* Mis and reckon. To reckon wrong; to compute wrong.

Whoever finds a mistake in the sum total, must allow himself out, though after repeated trials he may not see in which article he has *misreckoned*. *Swift.*

MISRELATE', *v. a.* } Mis and relate. To relate inaccurately or falsely: false or inaccurate narrative.
MISRELA'TION, *n. s.* }

Mine aim was only to press home those things in writing, which had been agitated between us by word of mouth; a course much to be preferred before verbal conferences, as being less subject to mistakes and *misrelations*, and wherein paralogisms are more quickly detected. *Bramhall.*

To satisfy me that he *misrelated* not the experiment, he brought two or three small pipes of glass, which gave me the opportunity of trying it. *Boyle*

MISREMEM'BER, *v. n.* & *v. a.* Mis and remember. To mistake by trusting to memory.

If I much *misremember* not, I had such a spirit from peas kept long enough to lose their verdure. *Boyle.*

MISREPORT', *v. a.* & *n. s.* Mis and report. To give a false account of: false or malicious representation.

His doctrine was *misreported*, as though he had every where preached this not only concerning the Gentiles, but also touching the Jews. *Hooker.*

A man that never yet
Did, as he vouches, *misreport* your grace.
Shakspeare.

We defend him not,
Only desire to know his crime: 'tis possible
It may be some mistake or *misreport*,
Some false suggestion, or malicious scandal.
Denham.

The wrong judgment that misleads us, and makes the will often fasten on the worst side, lies in *misreporting* upon the various comparisons of these. *Locke.*

As by flattery a man is usually brought to open his bosom to his mortal enemy, so by detraction, and a slanderous *misreport* of persons, he is often brought to shut the same even to his best and truest friends. *South's Sermons.*

MISREPRESENT', *v. a.* } Mis and re-
MISREPRESENTA'TION, *n. s.* } present. To falsify, or represent to disadvantage: the act of misrepresenting.

The character of the scholars of the present age will not be much injured or *misrepresented* by saying that they seem to be superficially acquainted with a multitude of subjects, but go to the bottom of very few. *Adventurer.*

Since I have shewn him his foul mistakes and injurious *misrepresentations*, it will become him publicly to own and retract them. *Atterbury.*

Two qualities necessary to a reader before his judgment should be allowed, are common honesty and common sense; and that no man could have *misrepresented* that paragraph, unless he were utterly destitute of one or both. *Swift.*

MISRULE', *n. s.* Mis and rule. Tumult; confusion; revel; unjust domination.

In the portal placed, the heaven-born maid,
Enormous riot, and *misrule* surveyed. *Pope.*
And through his airy hall the loud *misrule*
Of driving tempest is for ever heard. *Thomson.*

MISS, *n. s.* Contracted from mistress: but there is a Belgic *meisje*, a little girl: the term of honor to a young girl; also a concubine; a loose woman.

All women would be of one piece,
The virtuous matron and the *miss*. *Hudibras.*
This gentle cock, for solace of his life,
Six *misses* had besides his lawful wife. *Dryden.*

Where there are little masters and *misses* in a house they are great impediments to the diversions of the servants. *Swift.*

It cannot reasonably be doubted, but a little *miss*, dressed in a new gown for a dancing-school ball, receives as complete enjoyment as the greatest orator who triumphs in the splendour of his eloquence, while he governs the passions and resolutions of a numerous assembly. *Hume.*

Even *misses*, at whose age their mothers wore
The backstring and the bib, assume the dress
Of womanhood, sit pupils in the school
Of card-devoted time, and night by night
Placed at some vacant corner of the board,
Learn every trick, and soon play all the game.
Cowper.

MISS, *v. a.*, *v. n.* & *n. s.* Sax. mιʃʃan; Teut. and Belg. *missen;* Goth. and Swed. *missa*. To go beside a mark; not to hit an object of any kind; omit; do without; perceive or feel the omission, or want of something: as a neuter verb to fly away from a mark or object; fail; mistake; be lost; miscarry: as a substantive (obsolete or only used in low language) omission; loss; want; mistake; hurt or harm.

Thy shepherds we hurt not, neither was there ought *missing* unto them. 1 *Sam.* xxv. 7.

In vain have I kept all that this fellow hath in the wilderness, so that nothing was *missed*.
1 *Sam.* xxv. 21.

Without him I found a weakness, and a mistrustfulness of myself, as one strayed from his best strength, when at any time I *missed* him. *Sidney.*

In humble dales is footing fast,
The trode is not so tickle,
And though one fall through heedless haste,
Yet is his *misse* not mickle. *Spenser's Pastorals.*

He did without any great *miss* in the hardest points of grammar. *Ascham's Schoolmaster.*

Grittus *missing* of the Moldavian fell upon Maylat.
Knolles.

So may I, blind fortune leading me,
Miss that, which one unworthier may attain;
And die with grieving.
Shakspeare. Merchant of Venice.

We cannot *miss* him; he does make our fire,
Fetch in our wood. *Id. Tempest.*

My lord,
Upon my lady's *missing*, came to me
With his sword drawn. *Id.—Cymbeline.*

I could have better spared a better man.
Oh, I should have a heavy *miss* of thee,
If I were much in love with vanity.
Shakspeare.

The general root of superstition is, that men observe when things hit, and not when they *miss:* and commit to memory the one, and forget and pass over the other. *Bacon.*

If I die, the world shall *miss* me but a little: I shall *miss* it less. Not it me, because it hath such store of better men: not I it, because it hath so much ill, and I shall have so much happiness.
Bp. Hall.

To heaven their prayers
Flew up, nor *missed* the way. *Milton.*

For a time caught up to God, as once
Moses was in the mount, and *missing* long,
And the great Thisbite, who on fiery wheels
Rode up to heaven, yet once again to come. *Id.*

The invention all admired, and each, how he
To be the inventor *missed*, so easy it seemed,
Once found, which yet unfound most would have thought
Impossible. *Id. Paradise Lost.*

Flying bullets now
To execute his rage, appear too slow,
They *miss* or sweep but common souls away.
Waller.

Where shall a maid's distracted heart find rest,
If she can *miss* it in her lover's breast? *Dryden.*

When a man *misses* his great end, happiness, he will acknowledge he judged not right. *Locke.*

If these papers have that evidence in them, there will be no great *miss* of those which are lost, and my reader may be satisfied without them. *Id.*

He who was a firm, sincere friend, may want all the rest without missing them. *South*

She would never *miss* one day,
A walk so fine, a sight so gay. *Prior.*

The moral and relative perfections of the Deity are easy to be understood by us; upon the least reflection we cannot *miss* of them. *Atterbury.*

He that is so tender of himself, that he can never find in his heart so much as to *miss* a meal, by way of punishment for his faults, shews he is not much fallen out with himself. *Duty of Man.*

The life you boasted to your javelin given,
Prince, you have *missed.* *Pope.*

The man who threatens the world is always ridiculous; for the world can easily go on without him, and, in a short time, will cease to *miss* him. *Johnson.*

The good we never *miss* we rarely prize. *Cowper.*

MIS'SAL, *n. s.* Fr. *missel;* Lat. *missale.* The mass book of the Romish church.

By the rubrick of the *missal,* in every solemn mass, the priest is to go up to the middle of the altar. *Stillingfleet.*

MISSAY', *v. n.* Mis and say. To speak ill of; censure. Obsolete.

Their ill behaviour garres men *missay,*
Both of their doctrine and their fay. *Spenser's Pastorals.*

We are not dwarfs, but of equal stature, if Vives *missay* not. *Hakewill on Providence.*

MISSEEM', *v. n.* Mis and seem. To make false appearance.

Foul Duessa meet,
Who with her witchcraft and *misseeming* sweet
Inveigled her to follow her desires unmeet. *Faerie Queene.*

Never knight I saw in such *misseeming* plight. *Id.*

MISSERVE', *v. a.* Mis and serve. To serve unfaithfully.

Great men, who *misserved* their country, were fined very highly. *Arbuthnot on Coins.*

MISSHAPE', *v. a.* } Part. misshapen and mis-
MISSHA'PEN, *adj.* } shaped. Mis and shape. To shape ill or badly: ill-shaped: in Shakspeare, perhaps, it only signifies ill directed: as, to shape a course.

Him then she does transform to monstrous hues,
And horribly *misshapes* with ugly sights,
Captived eternally in iron mews. *Faerie Queene.*

A rude *misshapen,* monstrous rabblement. *Id.*

His monstrous scalp down to his teeth it tore,
And that misformed shape, *misshaped* more. *Id.*

Let the *misshaped* trunk that bears this head
Be round impaled with a glorious crown. *Shakspeare.*

Thy wit, that ornament to shape and love,
Misshapen in the conduct of them both,
Like powder in a skill-less soldier's flask,
I set on fire. *Id. Romeo and Juliet.*

If the world will be so vain as to *misshape* itself, we may not be so foolish as to follow it. *Bp. Hall.*

Pluto hates his own *misshapen* race,
Her sister furies fly her hideous face. *Dryden.*

Pride will have a fall: the beautiful trees go all to the wreck here, and only the *misshapen* and despicable dwarf is left standing. *L'Estrange.*

They make bold to destroy ill-formed and *misshaped* productions. *Locke.*

The Alps broken into so many steps and precipices, form one of the most irregular, *misshapen* scenes in the world. *Addison.*

We ought not to believe that the banks of the ocean are really deformed, because they have not the form of a regular bulwark; nor that the mountains are *misshapen,* because they are not exact pyramids or cones. *Bentley's Sermons.*

Some figures monstrous and *misshaped* appear,
Considered singly, or beheld too near,
Which but proportioned to their site or place,
Due distance reconciles to form and grace. *Pope.*

MIS'SILE, *adj.* Lat. *missilis.* Thrown by the hand; striking at distance.

We bend the bow, or wing the *missile* dart. *Pope.*

MISSIO, in Roman antiquity, was a full discharge given to a soldier after twenty years service, and differed from the exauctoratio, which was a discharge from duty after seventeen years service. Every soldier had a right to claim his missio at the end of twenty years.

MIS'SION, *n. s.* } Lat. *missio;* Fr. *missio-*
MIS'SIONARY, } *naire, missive.* Errand or
MIS'SIONER, } message from a supreme
MIS'SIVE. } authority: persons, taken collectively, sent on such an errand: used by Shakspeare for faction; party: in an obsolete sense, discharge; dismission. A missionary or missioner is an individual so sent. See below. A missive, a letter or messenger.

Glorious deeds, in these fields of late,
Made emulous *missions* 'mongst the gods themselves,
And drove great Mars to faction. *Shakspeare.*

Rioting in Alexandria, you
Did pocket up my letters; and with taunts
Did gibe my *missive* out of audience. *Id.*

Great aids came in to him; partly upon *missives,* and partly voluntary from many parts. *Bacon.*

In Cæsar's army, somewhat the soldiers would have had, yet only demanded a *mission* or discharge, though with no intention it should be granted, but thought to wrench him to their other desires; whereupon with one cry they asked *mission.* *Id.*

In these ships there should be a *mission* of three of the brethren of Solomon's house, to give us knowledge of the sciences, manufactures, and inventions of all the world, and bring us books and patterns; and that the brethren should stay abroad till the new *mission.* *Id. New Atlantis.*

Her son tracing the desert wild,
All his great work to come before him set,
How to begin, how to accomplish best,
His end of being on earth, and *mission* high. *Milton.*

Like mighty *missioner* you come,
Ad partes infidelium. *Dryden.*

In vain with darts a distant war they try,
Short, and more short, the *missive* weapons fly *Id.*

The king grants a license under the great seal, called a congé d'elire, to elect the person he has nominated by his letters *missive.* *Ayliffe's Parergon.*

The divine authority of our *mission,* and the powers vested in us by the high-priest of our profession, Christ Jesus, are publickly disputed and denied. *Atterbury.*

You mention the presbyterian *missionary,* who hath been persecuted for his religion. *Swift.*

MISSION, MISSIO, among the Romans, a term used to signify the emperor's sending to rescue a wounded gladiator from his antagonist. The munerarii, or persons who exhibited the games, and likewise the people, were allowed to rescue a favorite gladiator. The manner of their sig-

nifying this favor was pollice presso, or with the thumb hid in the palm of the hand. However, the gladiator was only saved for that time; whereas by the rudis he had a free discharge.

MISSION, in theology, denotes a commission to preach the gospel. Jesus Christ gave his disciples their mission in these words, 'Go and teach all nations,' &c. The Romanists reproach the Protestants that their ministers have, strictly, no mission, as not being authorised in the exercise of their ministry, either by an uninterrupted succession from the apostles, or by miracles, or by any extraordinary proof of a vocation. Many among Protestants hold a similar doctrine as to episcopal succession and ordination; while others deny any other mission necessary for their ministry than the talent to discharge it.

MISSION is also used for an establishment of people zealous for the glory of God and the salvation of souls; who go and preach the gospel in remote countries. Among the Romanists, the religious orders of St. Dominic, St. Francis, St. Augustine, &c., &c., have missions in the Levant, America, &c. The Jesuits had likewise missions in China, and all other parts of the globe where they were able to penetrate. Protestant missions, for diffusing the light of Christianity through the benighted regions of Asia, America, and the South Seas, are numerous. An early undertaking of this kind was the Danish mission planned by Frederic IV. in 1706. See MISSIONARY.

MISSIONARY SOCIETIES. Under this article we need only notice that the zealous and laudable exertions of various bodies of Christians, who, within these few years, have associated for the purpose of propagating the gospel both at home and abroad, are detailed by us under the names adopted by the principal societies. The most pleasing success has of late attended their labors, and the system can need no defence in these pages.

But a writer whom we have already quoted on the prospects of the church (see our article MILLENNIUM), the Rev. E. Irving, has boldly questioned the entire claims of these societies to a scriptural or apostolical character. He accuses the modern missionary societies of 'patching and mending, helping and repairing, and accommodating the unchangeable constitution of the Messiah to the changeable constitution of the world.' He insists that what he calls the missionary charter is contained in Matt. x. 5–42; and that the ninth and tenth verses are still binding on modern missionaries. In his own peculiar manner he exclaims, 'I have been tempted to indignation and wrath, that the institution and appointment of the great Head of the church should have been so widely departed from in these modern times, and, being honestly and plainly stated, should find so little favor in the eyes of a generation which prideth itself in the evangelical character of its missionary undertakings. And that, instead of going about to seek men who were advanced in faith to the height of the undertaking, they have gone about to reduce the undertaking to the measure of an ordinary faith, and have attracted to the service many who were hardly fit for a pastoral care in the church at home, much less for laying the foundation of Christian empire abroad. But most of all hath a holy indignation risen within my breast, when, to keep up the popular glory and renown of their work, which they should be ever rectifying by the word of God, they should be content rather to obliterate and annul that part of his holy word which is able to give them counsel. It is instructive of the self-exaltation of man to hear with what cool indifference they would consign to uselessness those immortal counsels which our Lord gave for the conduct of Christian missionaries, in order that they may have the field open for their own infallibility. They would break through all rules and laws of interpretation, and, to a passage whose every word and sentence breathes immortality, they would give a temporary application, destroying its obligation, losing its comfort, and abolishing its promises to the evil-entreated messenger of peace: all because it contains in its bosom two clauses which were necessary to make it useful and applicable to the time which then was, as well as to the times which were to come. Against this I have argued by an analysis of the passage, against it I have protested by an appeal to the apostolical times, in the hope of being able to prevail by argument and appeal; though, I confess with slender hope in a time when names or periodical organs of opinion have obtained almost the whole authority in the church.'

These novel views of the subject have been already animadverted upon by Mr. Orme of Camberwell. He contends that the language of Christ must be interpreted of those whom alone it can concern. 'I hold as decidedly as you,' he says in his Expostulatory Letter to Mr. Irving, 'that all who can preach the gospel are bound to preach the gospel; that all who can heal the sick, and cast out devils, are obliged to do so; that all who can speak with tongues, or interpret tongues, are called to exercise their gifts. Show me the man who can convey himself 10,000 miles across the pathless ocean without purse or scrip, who does not need to be brought on his way, or whose necessities, when at a distance, require not to be relieved, and I will show the man on whom the commands of Christ, in their most literal interpretation, are as binding now as they were when first delivered.

'But this leads us to the consideration of the obligations upon all missionaries literally to comply with all the injunctions of this discourse; particularly with those contained in verses nine and ten. You admit that there are in the discourse two, and only two, restrictive clauses, or local and temporary directions. These relate to the limits of the first commission, and the exclusion of the Gentiles and Samaritans. If I do not succeed in proving that there are several other peculiar and temporary circumstances involved in this document, I shall willingly submit to any epithet which you may think proper to apply.

'The apostles themselves, then, when they first received their Lord's instructions, were restricted, both by the nature of the commission, and by their inability to execute it in a more enlarged acceptation. They fulfilled it however

to the extent of their ability, and this was all that was required of them; and is all that Christ expects of us.

'In the second place I hope you will admit, Sir, that the part of the chapter which relates to 'healing the sick, cleansing the lepers, raising the dead, casting out devils,' is temporary, if not local; binding only on those who possess the power. I am sure I need not dwell on this; yet it constitutes another grand peculiarity of this missionary charter, and shows that there are more parts of it than you acknowledge binding only on a particular class of individuals.

'The third exceptive clause is that which you admit limits the field of labor to the land of Israel; but which I contend includes also what was peculiar to that land, and to this particular period of the apostolic ministry.

'Before taking up another point, I must refer to a fourth limitation or peculiarity in this charge. It occurs in the ninteenth and twenty-first verses. 'But when they deliver you up, take no thought how or what ye shall speak; for it shall be given you in that same hour what ye shall speak: for it is not ye that speak, but the spirit of your father that speaketh in you.' Do you mean to contend for the literal adoption of these words by all Christian ministers and missionaries? You do, indeed, say, 'that the assurance that the Lord would put into their mouth what they should say, hath always been the fountain of their [Christ's confessors] eloquence.' And you affirm that 'this hath been the judgment of the whole church.' Excuse me, Sir, from thinking that this is either the faith of the church or your own. 'Take no thought,—settle it in your hearts not to meditate before' (Luke xxi. 14), is a positive prohibition of premeditation, either respecting the testimony or the defence of the gospel; most appropriate to divinely inspired men, but utterly unsuitable to others. Does the minister of Hatton Garden not premeditate before he addresses his orations to the people? Did he take no thought, when, like Cicero, 'he retired into the quiet and peaceful country, to prepare himself with every preparation of the mind and of the spirit,' in order to the production of 'For Missionaries after the Apostolical School, a Series of Orations?' Yet this is child's play compared with being brought before kings and governors for Christ's sake.

'You anticipate an objection to the literal adoption of the prohibition respecting provision drawn from Luke xxii. 35—38. 'And he said unto them, When I sent you without purse, and scrip, and shoes, lacked ye any thing? And they said, Nothing. Then he said unto them, But now, he that hath a purse, let him take it, and likewise his scrip; and he that hath no sword, let him sell his garment, and buy one. For I say unto you, that this that is written must yet be accomplished in me, And he was reckoned among the transgressors: for the things concerning me have an end. And they said, Lord, behold, here are two swords. And he said unto them, It is enough.'

'I do not wonder, Sir, that you have put forth all your strength on this passage, which, I feel confident, must prove the ruin of your whole theory. I shall not enter into your general explanation, farther than to say, I do not perceive the force of many of your reasonings. You contend against the literal application of the latter part of the passage. So do I. You do so because a literal adoption of the command would be at variance with scripture and common sense; so think I. You limit obedience to the injunction to a particular, and that a very short period, the hour of our Lord's darkness and desolation. This is adopting the very ground of your opponents respecting local and temporary obligations. And then you abandon the literal interpretation altogether, and contend for a figurative meaning. In the following passage you have surrendered your cause, and relieved any one from following you farther:—

'In all this there is nothing which hath or can have a wider application than to that hour of darkness, during which the glory of his kingdom was eclipsed. And, even of this season, that it was not to be literally interpreted is manifest from the scene which immediately took place. The disciples, mistaking his meaning, made answer to him in these words, 'Lord, here are two swords.' And he answered them, 'It is enough;' that is, it is enough that I have reduced your minds from these high and towering expectations of power, which would have cast you upon ruin, to the lowly sense of your weakness, and the prudent thought of your safety. But they, imagining that he really meant them to use these two swords with which they were provided, said, when the rout came upon him in the garden, 'Lord, shall we smite with the sword?' And Peter actually lifted up his sword, and smote the high priest's servant, and cut off his ear; to which action our Lord made the reply, 'Put up again thy sword into his place: for all they that take the sword shall perish by the sword.' Which shows that not only did he not intend the sentence under consideration to be understood of the propagation, but not even of the defence of his cause; that, so far from intending it to be applied literally to all times, he did not intend it to be literally applied even to that time of oppression, for the sake of which it was spoken. That it was to be understood, as we have explained it, for a strong and figurative way of reducing their minds from the ambitious thoughts of a power which their question indicated, down to a lowly sense of their true condition, its trials, and its dangers.'

We recommend the whole of this masterly letter to the consideration of such of our readers as feel interested in this important subject.

Missionary Society, Church. See Society, Church Missionary.

MISSISSIPPI, a river of the United States of North America, which rises from Ibasca Lake, long. 95° 8' W., lat. 47° 47' N., and, after a course of about 600 miles, reaches the falls of St. Anthony in lat. 44° N. It forms a junction with the Missouri in lat. 38° 50' N., and flows into the Gulf of Mexico by several mouths, the principal of which, called the Balize, is in long. 89° 30' W., lat. 29° 6' N.

This river overflows its banks every spring, and lays the country, for many miles in exten-

under water. It is from one to two miles in width, and of an uncommon depth. The navigation is difficult and dangerous. Vessels are from five to thirty days on their passage up to New Orleans; though, with a favorable wind, they will sometimes descend in twelve hours. From New Orleans to the Illinois the voyage requires eight or ten weeks. Boats of forty tons ascend to St. Anthony's Falls; but ships seldom ascend above Natchez. The navigation is now greatly facilitated by the use of steam-boats, the tonnage of six of which, some time since, exceeded 300, and one 400, tons. They are employed with great advantage, and their number is rapidly increasing. The principal towns on the Mississippi are New Orleans, Natchez, and St. Louis.

The whole length of the Mississippi is about 3000 miles. The length, above its junction with the Missouri, upwards of 1600 miles. The length of the Missouri, above the junction, is 3096 miles. The Missouri, being both longer and larger, may properly be considered the main river. On this principle the following table is constructed, exhibiting a view of the principal tributaries of this unrivalled stream. The first column expresses the distance of one junction from the preceding, the second the distance of the junction from the entrance into the Gulf of Mexico by the course of the stream, and the third the estimated length of the tributary river.

	Dist.	Whole Dist.	Length.
Red River		344	1500
Arkansaw	398	500	2170
White River	14	514	1200
Ohio	336	1092	1350
Mississippi	192	1284	1620
Osage	133	1417	600
Grand	107	1524	600
Kansas	100	1624	1200
Platte	260	1884	1800
Yellowstone	1280	3164	1100

BRANCHES OF THE TRIBUTARIES.

Branches of the Mississippi.

	Length.
Illinois	500
Moines	800
Of the Ohio.	
Tennessee	1100
Cumberland	750
Of Red River.	
Ouachitta	600
Of the Yellowstone.	
Bighorn	800

The above distances from the mouth of the Mississippi to the junction of the Missouri are given according to Mr. Darby. Some others make the distances greater. Above the junction the distances are given according to Lewis and Clark. Besides the above, there are a great number of other rivers, many of them large, that flow into the Mississippi and its tributaries.

The following table exhibits an estimate of the extent of country watered by this river and its branches. It comprises nearly three-fifths of the whole territory of the United States.

	Square Miles.
Missouri Territory, 2-3	1,000,000
Northwest Territory, ½	73,500
Illinois Territory, the whole	52,000
Indiana, 19-20	35,150
Ohio, 4-5	31,300
Pennsylvania, 1-3	14,600
New York, 1-100	460
Maryland, 1-100	120
Virginia, 2-5	25,600
North Carolina, 1-50	960
South Carolina, 1-150	190
Georgia, 1-100	620
Kentucky, the whole	42,000
Tennessee, the whole	40,000
Mississippi, 3-5	27,000
Louisiana, 2-3	32,000
Total,	1,375,500

Mississippi is one of the United States of North America, erected into a state in 1817; bounded north by Tennessee, east by Alabama Territory, south by the Gulf of Mexico and Louisiana, and west by Pearl and Mississippi Rivers, which separate it from the state of Louisiana. Long. 80° 30′ to 81° 35′ W., lat. 30° 10 to 35° N. 312 miles long from north to south, and 150 from east to west; containing about 45,000 square miles.

The Mississippi Territory was divided, in 1817, into two parts nearly equal; the western part forming the state of Mississippi, and the eastern forming the Alabama Territory. The population of the whole, in 1810, was 40,352; and, in 1830, 136,806, of whom 65,659 were slaves. The counties, population, and chief towns of the state of Mississipi, in 1816, are exhibited in the following table:—

Counties.	Pop.	Chief Towns.
Adams	12,129	Natchez
Amite	7,943	Liberty
Claiborne	9,818	Port Gibson
Franklin	4,622	Meadville
Greene	1,849	Leaksville
Hancock	1,961	Pearlington
Jefferson	9,755	Fayette
Lawrence	5,321	Monticello
Marion	3,701	Columbia
Pike	5,402	Holmesville
Warren	7,661	Warren
Wayne	2,778	Winchester
Wilkinson	11,693	Woodville
Washington	1,976	Princeton
Yaroo	6,550	Benton

These are the principal counties.

Monticello is the present seat of government. Natchez is the largest town, and Washington is next to Natchez in size. The other towns in the state are very small. A bank is established at Natchez with a capital of 3,000,000 dollars, having several branches. A college was incorporated, in 1802, at Washington, and another has been recently incorporated at Shieldsborough. There are academies at Natchez, Monticello, and Woodville.

The principal rivers are the Mississippi, Pearl, Pascagoula, Yazoo, Black, Tennessee, and the western branches of the Tombigbee. The Mississippi forms the western boundary from lat. 31° to 35° N.; 308 miles in a right line, but, by the course of the river, nearly 700 miles.

The southern part of the territory, extending about 100 miles north from the Gulf of Mexico, is mostly a champaign country, with occasional hills of moderate elevation, and is covered with forests of the long leaved pine, interspersed with cypress swamps, open prairies, and inundated marshes. A considerable portion of this part is susceptible of cultivation. The soil is generally sandy, sometimes gravelly and clayey. It is capable of producing cotton, corn, indigo, sugar, garden vegetables, plums, cherries, peaches, figs, sour oranges, and grapes. In proceeding north the face of the country becomes more elevated and agreeably diversified. The growth of timber consists of poplar, hickory, oak, black walnut, sugar-maple, buckeye, elm, hackberry, &c.; and the soil is exceedingly fertile, producing abundant crops of cotton, corn, sweet potatoes, indigo, garden vegetables, and fruit. Nearly all the country watered by the Yazoo is described as incomparably fertile, well-watered, and healthful.

Cotton is the staple production of the state. Tobacco and indigo have both been cultivated; but the former is nearly, and the latter entirely, abandoned by the planters. Peaches and figs are the fruits most easily produced. Apples, plums, lemons, and oranges, are common. The climate is temperate, and in the elevated parts generally healthy. The local situation of this state, the fertility of its soil, the temperature of its climate, and the value of its productions, will doubtless cause it to remain an important part of the union.

The Choctaw and Chickasaw Indians possess a large portion of the territory of this state, embracing the northern and eastern parts. The tracts possessed by these tribes comprise some of the finest parts of the state, abounding with extensive and beautiful prairies.

MISSON (Francis Maximilian), an eminent French lawyer, who distinguished himself by his pleadings before the parliament of Paris in favor of the reformers. He retired into England after the revocation of the edict of Nantz, and became a strenuous advocate of the Protestant religion. In 1687 and 1688 he travelled to Italy as governor to an English nobleman; in consequence of which he published, at the Hague, A New Voyage to Italy, 3 vols. 12mo.; which was translated into English with many additions. He published also the Sacred Theatre at Cevennes, or An Account of Prophecies and Miracles performed in that part of Languedoc; London, 1707; Observations and Remarks of a Traveller, 12mo., Hague. He died at London in 1721.

MISSOURI, a river of North America, which rises in the rocky mountains, and, uniting with the Mississippi, flows into the gulf of Mexico. The three head branches are Jefferson's, Madison's, and Gallatin's Rivers, which are navigable for some distance. The following table of distances is taken from Lewis and Clark's Travels; and the distance, from the junction with the Mississippi to the gulf of Mexico, from Schultz.

From the extreme point of navigation, in long. 111° 45′ W., lat. 43° 31′ N., to

	Miles.	Whole Dist.
The Gates of the Rocky Mountains	411	411
Great Falls	110	521
Yellowstone River . . .	695	1216
Fort Mandan	280	1496
Chyenne River	290	1786
Platte River	710	2496
Kansas River	260	2756
Grand River	100	2856
Osage River	107	2963
Mississippi River . . .	133	3096
Gulf of Mexico . . .	1395	4491

The only interruption of the navigation through this whole distance is at the Great Falls. At these falls the river descends, in the space of eighteen miles, 357 feet. The greatest cascade is eighty-seven feet perpendicular, and exhibits a view of singular beauty and grandeur. There is another pitch of forty-seven feet. About 100 miles below these falls there are natural walls of stone, in several places, on the banks of the river. They rise 200 or 300 feet high, nearly perpendicular, exhibit a most extraordinary and romantic appearance, and are regarded as a great curiosity. The place where the river makes its escape from the mountains, called the 'Gates of the Rocky Mountains,' presents an object of extraordinary curiosity. For the distance of five miles and three-quarters the rocks rise perpendicularly from the water's edge nearly 1200 feet. The river is here compressed to the width of 150 yards; and, for the first three miles, there is but one spot, and that of only a few yards, on which a man could stand between the water and the perpendicular ascent of the mountain. From the Mississippi to the Great Falls the Missouri is not difficult of navigation; but, above the falls, the navigation is considerably obstructed by rocks and rapid currents. The breadth of this river, at its junction with the Mississippi, is from half to three-quarters of a mile; its waters are very turbid and muddy. See MISSISSIPPI.

MISSOURI TERRITORY, a country belonging to the United States. In the most extended sense it includes all the country of Louisiana not comprised within the limits of the state of Louisiana. For its extent, boundaries, &c., see LOUISIANA.

If the western boundary of the state of Louisiana were continued due north to lat. 40° 30′ N., and a line extended thence due east to the Mississippi, these limits, with the Mississippi on the east, and the state of Louisiana on the south, would include all the settlements made in the Missouri Territory, except on the Missouri and Mississippi rivers. The number of square miles in this region is about 98,000, of which 16,000 lie north, and 82,000 south, of the Missouri. The extended line on the western side would cross the Missouri fifteen or twenty miles below the mouth of the Kansas.

In 1810 this territory was divided into five districts, and contained 20,895 inhabitants, of whom 3618 were blacks.

In 1830 it comprised 33 counties, the principal of which, with their chief towns, are exhibited in the following table.

Counties.	Chief Towns.
Boon	Columbia
Cape Girardeau	Jackson
Howard	Fayette
Lincoln	Troy
New Madrid	New Madrid
St. Charles	St. Charles
St. Genevieve	St. Genevieve
St. Louis	St. Louis
Washington	Potosi
Wayne	Greenville.

The present population is estimated at about 140,074. St. Louis is the chief town. The other most considerable towns are St. Charles, St. Genevieve, Jackson, and Franklin. There are two banks at St. Louis. The principal rivers are the Mississippi, Missouri, Osage, Grand, Charlatan, Marameck, St. Francis, White, Arkansaw, and Ouachitta.

There are extensive alluvial tracts on all the rivers. This land, where it is not subject to inundation, is of excellent quality. Howard county, sometimes called Boone's Lick, which lies on both sides of the Missouri, extending south as far as Osage River, is represented as including some of the most fertile tracts in America. The land produces abundant crops of wheat, Indian corn, rye, oats, barley, potatoes, white clover, timothy, and blue grass. Various kinds of garden vegetables and fruits are cultivated. The forest trees are walnut, hickory, various kinds of oak, locust, ash, cotton-wood, pawpaw, coffee nut, sycamore, elm, maple, hackberry, box, &c. The climate is very pleasant and healthy.

The land in this territory on the Arkansaw is mostly alluvial, and, where not liable to inundation, excellent. The region watered by White River has immense strata of limestone and marble, and a great portion of it is of a very productive soil. Here are some prairies, but they are not very fertile or extensive. The country watered by the St. Francis is less fertile than that watered by White River. The country between these two rivers, for more than 100 miles above their junction, is overflowed; as is also the country between the St. Francis and the Mississippi. The southern part of the territory is well adapted to the culture of cotton, and some cotton is raised for domestic use north of Osage River.

This territory has an abundance of salt springs, from which salt is manufactured. It also has coal, iron, and lead mines. The famous lead mines of this country include a district about fifty miles in length, and twenty-five in breadth; the whole of which abounds in lead ore, so exceedingly rich that 100 lbs. of the ore will yield eighty or ninety of fine lead. The mines are so extensive that it is supposed that lead enough might be obtained from them to supply the world. They are forty-five miles west of Herculaneum, which is the present store-house of the mines.

Missouri, Little, a river of Louisiana, which runs into the Missouri 1690 miles from the Mississippi. Length about 500 miles.

MISSPEAK, *v. a.* & *v. n.* Mis and speak. To speak wrong; blunder in speech.

> It is not so; thou hast *mispoke*, misheard,
> Tell o'er thy tale again. *Shakspeare. King Lear.*
> A mother delights to hear
> Her early child *misspeak* half-uttered words.
> *Donne.*

MISSUS, in the Circensian games, were the matches in horse or chariot races. The usual number of missus or matches in one day was twenty-four; though Domitian presented the people with 100. The last match was generally made at the expense of the people, who made a collection for the purpose; hence it was called, Missus Ærarius, a subscription plate.

MIST, *n. s.* & *v. a.*, Mis'tiness, *n. s.*, Mis'ty, *adj.* } Sax. mirt; Belg. and Teut. *mist*. Vapor; a low thin cloud; small thin rain: hence metaphorically any thing that bedims or darkens: Shakspeare uses it as a verb for to cover with a cloud or vapor: misty is cloudy; vapory.

> The morrow fair with purple beams
> Dispersed the shadows of the *misty* night.
> *Faerie Queene.*

> Loud howling wolves arouse the jades,
> That drag the tragick melancholy night;
> Who with their drowsy, slow, and flagging wings
> Clip dead men's graves, and from their *misty* jaws
> Breathe foul contagious darkness in the air.
> *Shakspeare.*

> Good Romeo, hide thyself,
> —Not I, unless the breath of heart-sick groans
> *Mistlike* infold me from the search of eyes. *Id.*

> Lend me a looking-glass;
> If that her breath will *mist* or stain the stone,
> Why then she lives. *Id. King Lear.*

The speedy depredation of air upon watery moisture, and version of the same into air, appeareth in the sudden vanishing of vapours from glass, or the blade of a sword, such as doth not at all detain or imbibe the moisture, for the *mistiness* scattereth immediately. *Bacon.*

Parents overprize their children, while they behold them through the vapours of affection, which alter the appearance, as things seem bigger in *misty* mornings. *Wotton.*

My people's eyes once blinded with such *mists* of suspicion, they are misled into the most desperate actions. *King Charles.*

> Old Chaucer, like the morning star,
> To us discovers day from far;
> His light those *mists* and clouds dissolved
> Which our dark nation long involved.
> *Denham.*

> And *mists* condensed to clouds obscure the sky,
> And clouds dissolved the thirsty ground supply.
> *Roscommon.*

> His passion cast a *mist* before his sense,
> And either made or magnified the offence.
> *Dryden.*

A cloud is nothing but a *mist* flying high in the air, as a *mist* is nothing but a cloud here below. *Locke.*

As a *mist* is a multitude of small but solid globules, which therefore descend; so a vapour, and therefore a watery cloud, is nothing else but a congeries of very small and concave globules, which therefore ascend to that height in which they are of equal weight with the air, where they remain suspended, till by some motion in the air, being broken,

they descend in solid drops; either small, as in a *mist*, or bigger, when many of them run together, as in rain. *Grew.*

Now smoaks with showers the *misty* mountain ground,
And floated fields lie undistinguished round. *Pope.*

Are *mists* begotten? who their Father knew?
From whom descend the pearly drops of dew? *Young.*

All in this mottie, *misty* clime,
I backward mused on wasted time,
How I had spent my youthfu' prime,
An' done nae-thing. *Burns.*

MISTAKE', *v. a., v. n. & n. s.* } Mis and take. To take or conceive wrongfully; err: mistake is also put for the misconception or error made: mistakable, is liable to be misconceived: mistakingly, erroneously; foolishly or falsely.
MISTA'KABLE, *adj.*
MISTA'KINGLY, *adv.*

The towns, neither of the one side nor the other, willingly opening their gates to strangers, nor strangers willingly entering for fear of being *mistaken*. *Sidney.*

This dagger hath *mistaken*, for lo! the sheath
Lies empty on the back of Montague,
The point missheathed in my daughter's bosom. *Shakspeare.*

England is so idly kinged:
—You are too much *mistaken* in this king:
Question, your grace, the late ambassadors,
How modest in exception, and withal
How terrible in constant resolution. *Id.*

Seeing God found folly in his angels; men's judgments, which inhabit these houses of clay, cannot be without their *mistakings*. *Raleigh.*

The most general enmities and oppositions to good arise from *mistakings*. *Bp. Hall.*

He never shall find out fit mate; but such
As some misfortune brings him, or *mistake*. *Milton.*

Look, nymphs, and shepherds, look,
What sudden blaze of majesty,
Too divine to be *mistook*. *Id.*

It is not strange to see the difference of a third part in so large an account, if we consider how differently they are set forth in minor and less *mistakeable* numbers. *Browne.*

Mistaken Brutus thought to break their yoke,
But cut the bond of union with that stroke. *Waller.*

The error is not in the eye, but in the estimative faculty, which *mistakingly* concludes that colour to belong to the wall which does indeed belong to the object. *Boyle on Colours.*

Infallibility is an absolute security of the understanding from all possibility of *mistake* in what it believes. *Tillotson.*

These did apprehend a great affinity between their invocation of saints and the heathen idolatry, or else there was no danger one should be *mistaken* for the other. *Stillingfleet.*

This will make the reader very much *mistake* and misunderstand his meaning. *Locke.*

Fancy passes for knowledge, and what is prettily said is *mistaken* for solid. *Id.*

Those terrors are not to be charged upon religion, which proceed either from the want of religion, or superstitious *mistakes* about it. *Bentley.*

Fools into the notion fall,
That vice or virtue there is none at all:
Ask your own heart, and nothing is so plain
'Tis to *mistake* them costs the time and pain. *Pope.*

Servants *mistake*, and sometimes occasion misunderstanding among friends. *Swift.*

There are few, very few, that will own themselves in a *mistake*, though all the world see them to be in downright nonsense. *Id.*

Where men are the most sure and arrogant, they are commonly the most *mistaken*, and have there given reins to passion, without that proper deliberation and suspense, which can alone secure them from the grossest absurdities. *Hume.*

MISTAKEN POINT, a point on the west of Cape Race and east of Cape Pini, at the south-east point of the island of Newfoundland.

MISTATE', *v. a.* Mis and state. To state wrongly.

They *mistate* the question, when they talk of pressing ceremonies. *Bp. Saunderson.*

MISTEACH', *v. a.* Mis and teach. To teach wrong, or wrongly.

Such guides shall be set over the several congregations as will be sure to *misteach* them. *Saunderson.*

The extravagancies of the lewdest life are the more consummate disorders of a *mistaught* or neglected youth. *L'Estrange.*

MISTEM'PER, *v. a.* Mis and temper. To temper ill; to disorder.

This inundation of *mistempered* humour
Rests by you only to be qualified. *Shakspeare.*

MIS'TER, *adj.* Fr. *mestier*, trade. What mister means what kind of. Johnson. Obsolete.

The redcross knight toward him crossed fast,
To weet what *mister* wight was so dismayed,
There him he finds all senseless and aghast. *Spenser.*

MISTERM', *v. a.* Mis and term. To term erroneously.

Hence banished, is banished from the world;
And world exiled is death. That banished
Is death *mistermed*. *Shakspeare. Romeo and Juliet.*

MISTHINK', *v. a.* Mis and think. To think ill; to think wrong.

How will the country, for these woful chances,
Misthink the king, and not be satisfied! *Shakspeare.*

We, the greatest, are *misthought*
For things that others do. *Id. Anthony and Cleopatra.*

Thoughts! which how found they harbour in thy breast,
Adam! *Misthought* of her to thee so dear! *Milton.*

MIS'TION, *n. s.* Lat. *mistus*. The state of being mingled.

In animals many actions are mixt, and depend upon their living form as well as that of *mistion*, and though they wholly seem to retain unto the body, depart upon disunion. *Browne.*

Both bodies do, by the new texture resulting from their *mistion*, produce colour. *Boyle on Colours.*

MISTLETOE, *n. s.* Sax. mıꞅtelꞇan; Belg. *mistel*, bird-lime, and ꞇan, a twig. A plant. See below.

If snowe do continue, sheepe hardly that fare
Crave *mistle* and ivie for them for to spare. *Tusser.*

A barren and detested vale, you see it is:
The trees, though Summer, yet forlorn and lean,
Overcome with moss, and baleful *misseltoe*. *Shakspeare.*

Misseltoe groweth chiefly upon crab trees, apple trees, sometimes upon hazles, and rarely upon oaks; the *misseltoe* whereof is counted very medicinal: it is ever green Winter and Summer, and beareth a white

glistering berry; and it is a plant utterly differing from the plant upon which it groweth. *Bacon.*

All your temples strow
With laurel green, and sacred *misletoe.* *Gay.*

MISTLETOE. See VISCUM. The flower of the mistletoe consists of one leaf, which is shaped like a basin, divided into four parts, and beset with warts; the ovary, which is produced in the female flowers, is placed in a remote part of the plant from the male flowers, and consists of four shorter leaves; this becomes a round berry full of a glutinous substance, enclosing a plain heart-shaped seed. This plant is always produced from seed, and is not to be cultivated in the earth, but will always grow upon trees; whence the ancients, who thought it to be an excrescence on the tree without seed, accounted it a superplant. The manner of its propagation is said to be as follows: the misletoe thrush, which feeds upon the berries of this plant in winter, when they are ripe, opens the seed from tree to tree; for the viscous part of the berry, which immediately surrounds the seed, sometimes fastens it to the outward part of the bird's beak, which to get disengaged of, he strikes his beak at the branches of a neighbouring tree, and leaves the seed sticking by this viscous matter to the bark, which, if it lights upon a smooth part of the tree, will fasten itself, and the following winter put out and grow: the trees on which this plant grows most readily are the apple, the ash, and some other smooth rind trees.

MIS'TRESS, *n. s.* Fr. *maistresse.* The feminine of master; a woman who possesses, governs, or is skilled in something: a contemptuous cognomen; a concubine.

There had she enjoyed herself while she was *mistress* of herself, and had no other thoughts but such as might arise out of quiet senses. *Sidney.*

Here stood he in the dark, his sharp sword out,
Mumbling of wicked charms, conjuring the moon
To stand 's auspicious *mistress.*
Shakspeare. King Lear.

Let us prepare
Some welcome for the *mistress* of the house.
Shakspeare.

He'll make your Paris Louvre shake for it,
Were it the *mistress* court of mighty Europe. *Id.*

I will not charm my tongue; I'm bound to speak;
My *mistress* here lies murthered in her bed.
Id. Othello.

Look you pale, *mistress,*
Do you perceive the ghastness of her eyes?
Shakspeare.

Rome now is *mistress* of the whole world, sea, and land, to either pole. *Ben Jonson's Catiline.*

They would not suffer the prince to confer with, or very rarely to see, his *mistress,* whom they pretended he should forthwith marry. *Clarendon.*

Wonder not, sovereign *mistress!* if perhaps
Thou can'st, who art sole wonder; much less arm
Thy looks, the heaven of mildness, with disdain.
Milton.

This is indeed the highest philosophy; the true culture and medicine of our soul; the true guide of life, and *mistress* of action; the mother of all virtues. *Barrow.*

Ages to come, that shall your bounty hear,
Will think you *mistress* of the Indies were;
Though straiter bounds your fortune did confine,
In your large heart was found a wealthy mine.
Waller.

A letter desires all young wives to make themselves *mistresses* of Wingate's Arithmetic. *Addison.*

Those who assert the lunar orb presides
O'er humid bodies, and the ocean guides;
Whose waves obsequious ebb, or swelling run
With the declining or increasing moon;
With reason seem her empire to maintain
As *mistress* of the rivers and the main.
Blackmore.

What a miserable spectacle, for a nation that had been *mistress* at sea so long! *Arbuthnot on Coins.*

Nice honour still engages to requite
False *mistresses* and proud with slight for slight.
Granville.

Erect public schools, provided with the best and ablest masters and *mistresses.* *Swift.*

Fame is a public *mistress* none enjoys
But, more or less, his rivals' peace destroys;
With fame, in just proportion, envy grows;
The man that makes a character makes foes.
Young.

Sweet Poll! his doting *mistress* cries,
Sweet Poll! the mimic bird replies,
And calls aloud for sack. *Cowper.*

MISTRETTA, a large inland town of Sicily, in the Val di Demona, situated on a small river, about five miles from the great road from Palermo to Messina. Population 6000. Fifty miles east by south of Palermo.

MISTRUST', *n. s.* & *v. a.*
MISTRUST'FUL, *n. s.*
MISTRUST'FULNESS, *n. s.*
MISTRUST'FULLY, *adv.*
MISTRUST'LESS, *adj.*
} Mis and trust. Suspicion; want of confidence; diffidence: to mistrust is to doubt; suspect; disbelieve: the other derivatives follow these senses.

Without him I found a weakness, and a *mistrustfulness* of myself, as one strayed from his best strength, when at any time I missed him. *Sidney.*

Will any man allege those human infirmities, as reasons why these things should be *mistrusted* or doubted of? *Hooker.*

He needs not our *mistrust,* since he delivers
Our offices, and what we have to do,
To the direction just. *Shakspeare. Macbeth.*

By a divine instinct, men's minds *mistrust*
Ensuing danger; as by proof we see,
The waters swell before a boisterous storm.
Shakspeare

I hold it cowardice
To rest *mistrustful,* where a noble heart
Hath pawned an open hand in sign of love. *Id.*

Where he doth in stream *mistrustless* play,
Veiled with night's robe, they stalk the shore abroad.
Carew.

How shall I depend on him, for raising my body from dust, and saving my soul, if I *mistrust* him for a crust of bread towards my preservation?
Bp. Hall.

Fate her own book *mistrusted* at the sight,
On that side war, on this a single fight. *Cowley.*

Not then *mistrust,* but tender love, injoins
That I should mind thee oft; and mind thou me!
Milton.

The relation of a Spartan youth, that suffered a fox concealed under his robe to tear out his bowels, is *mistrusted* by men of business. *Browne.*

Here the *mistrustful* fowl no harm suspects,
So safe are all things which our king protects.
Waller.

The generous train complies,
Nor fraud *mistrusts* in virtue's fair disguise.
Pope.

How aften didst thou pledge and vow,
Thou wad for aye be mine!
And my fond heart, itsel sae true,
It ne'er *mistrusted* thine. *Burns.*

MISUND'ERSTAND, *v. a.* } Mis and understand. To mistake; misinterpret; misconceive; difference of understanding: dissension; disagreement.
MISUND'ERSTANDING, *n. s.* }

The words of Tertullian, as they are by them alledged, are *misunderstood.* *Hooker.*

He failed in distinguishing two regions, both called Eden, and altogether *misunderstood* two of the four rivers. *Raleigh.*

Sever the construction of the injury from the point of contempt, imputing it to *misunderstanding* or fear. *Bacon.*

There is a great *misunderstanding* betwixt the corpuscular philosophers and the chemists. *Boyle.*

This, if it be neglected, will make the reader very much mistake and *misunderstand* his meaning. *Locke.*

In vain do men take sanctuary in such *misunderstood* expressions as these; and, from a false persuasion that they cannot reform their lives, never go about it. *South.*

Were they only designed to instruct the three succeeding generations, they are in no danger of being *misunderstood.* *Addison.*

The example of a good man is the best direction we can follow in the performance of our duty; the most exact rules and precepts are subject to be *misunderstood*; some at least will mistake their meaning. *Rogers's Sermons.*

Servants mistake, and sometimes occasion *misunderstandings* among friends. *Swift.*

MISUSE', *v. a.* } Fr. *mesuser*, mis and use. To treat or use improperly; to abuse: misusage is ill usage; bad treatment.
MISU'SAGE, *n. s.* }

You *misuse* the reverence of your place,
As a false favorite doth his prince's name
In deeds dishonourable. *Shakspeare. Henry IV.*

Upon whose dead corpse there was such *misuse*,
Such beastly, shameless transformation,
By those Welshwomen done, as may not be
Without much shame retold. *Shakspeare.*

It hath been their custom shamefully to *misuse* the fervent zeal of men to religious arms, by converting the monies that have been levied for such wars to their own services. *Raleigh.*

Bacchus, that first from out the purple grape
Crushed the sweet poison of *misused* wine. *Milton.*

How names taken for things mislead the understanding, the attentive reading of philosophical writers would discover, and that in words little suspected of any such *misuse.* *Locke.*

Machiavel makes it appear, that the weakness of Italy, once so strong, was caused by the corrupt practices of the papacy, in depraving and *misusing* religion. *South.*

We have reason to humble ourselves before God by fasting and prayer, lest he should punish the *misuse* of our mercies, by stopping the course of them. *Atterbury.*

MISWEEN', *v. n.* Mis and ween. To misjudge; to distrust. Obsolete.

Latter times things more unknown shall show,
Why then should witless man so much *misween*?
Faerie Queene.

MISWEND', *v. n.* Mis and Sax. penðan, to go. To go wrong. Obsolete.

Every thing begun with reason,
Will come by ready means unto his end:
But things miscounselled must needs *miswend.*
Hubberd.

In this maze still wandered and *miswent*,
For heaven decreed to conceal the same,
To make the miscreant more to feel his shame.
Fairfax

MI'SY, *n. s.* Gr. μισυ. A kind of mineral.

Misy contains no vitriol but that of iron: it is a very beautiful mineral, of a fine bright yellow colour, of friable structure, and resembles the golden marcasites. *Hill.*

MITCHELSTOWN, a post town of Ireland, in the county of Cork, 102 miles from Dublin. It has a college for the support of twelve decayed gentlemen and twelve gentlewomen, who have £40 yearly, with handsome apartments, and a chaplain at £100 a year, with a house. Divine service is daily performed in a neat chapel belonging to the college: the whole was founded by the late earl of Kingston. Here is also a most magnificent seat of lord Kingsborough. Near this town, at the foot of one of the Galtee mountains, is the cave of Skeheenrinky, which is described by Arthur Young in his Irish Tour, and preferred by him to the famous cave in the peak of Derbyshire, as it was by lord Kingsborough to the Grot d'Aucel in Burgundy. Fairs are held on the 30th July and 12th November.

MITE, *n. s.* Fr. *mite*; Belg. *migt*, *myte*; Teut. *meit*, *macte*; all, perhaps, of Goth. *mith*, minute. A small insect; small coin or particle; any thing very small.

And he saw a certain poor widow casting in thither two mites: and he said, Of a truth I say unto you, that this poor widow hath cast in more than they all. *Luke* xxi. 43.

Through any man's corn they do bite,
They will not allow him a *mite.* *Tusser.*

Virginity breeds *mites*, like a cheese consumes itself to the very paring, and dies with feeding its own stomach. *Shakspeare.*

Are you defrauded, when he feeds the poor?
Our *mite* decreases nothing of your store. *Dryden.*

The idea of two is as distinct from the idea of three, as the magnitude of the earth from that of a *mite.* *Locke.*

Put blue-bottles into an ant-hill, they will be stained with red, because the ants thrust in their stings, and instil into them a small *mite* of their stinging liquor, which hath the same effect as oil of vitriol. *Ray on the Creation.*

The polished glass, whose small convex
Enlarges to ten millions of degrees
The *mite* invisible else, of nature's hand
Least animal. *Philips.*

The Seville piece of eight contains thirteen penny weights twenty-one grains and fifteen *mites*, of which there are twenty in the grain, of sterling silver, and is in value forty-three English pence and eleven hundredths of a penny. *Arbuthnot.*

Did I e'er my *mite* with-hold
From the impotent and old? *Swift.*

MITE, in zoology. See ACARUS.

MITE, in Jewish antiquity, a small piece of money mentioned in Luke xii. 59, and xxi. 2. In the Greek it is Λεπτὸν, and is one half of the Κοδράντης, and therefore one-eighth of the Roman denarius, or of sevenpence-halfpenny of our money.

MITELLA, bastard American sanicle, a genus of the digynia order and decandria class of plants; natural order thirteenth, succulentæ: CAL. quinquefid: COR. pentapetalous, and inserted into the calyx; petals pinnatifid: CAPS. unilocular and bivalved, with the valves equal. There are four species, all natives of North America, rising with annual herbaceous stalks, from five or six to eight or nine inches, and producing spikes of small whitish flowers, whose petals are fringed on their edges. They are easily propagated, by parting their roots, in a shady situation and soft loamy soil.

MITHRA, or MITHRAS, a god of Persia and Chaldea, supposed to be the sun. He is generally represented as a young man, whose head is covered with a turban after the manner of the Persians. He supports his knee upon a bull that lies on the ground, and one of whose horns he holds in one hand, while with the other he plunges a dagger into his neck. The grand festival of Mithras was celebrated six days in the middle of the month of Mihir, which began September 30th and ended October 30th. On these days only was it lawful for the kings of Persia to get drunk and dance.

MITHRAS, FEASTS OF, in antiquity, feasts celebrated among the Romans in honor of Mithras. The most ancient instance of this worship among the Romans occurs in an inscription dated in the third consulate of Trajan, or about A. D. 101, on an altar thus inscribed, Deo Soli Mithræ. But the worship of Mithras was not known in Egypt and Syria in the time of Origen, who died about A. D. 263. The worship of Mithras was proscribed at Rome in 378 by order of Gracchus prefect of the prætorium. According to M. Freret, the feasts of Mithras were derived from Chaldea, where they had been instituted for celebrating the entrance of the sun into the sign Taurus.

MITH'RIDATE, *n. s.* Fr. *mithridate.*

Mithridate is one of the capital medicines of the shops, consisting of a great number of ingredients, and has its name from its inventor Mithridates, king of Pontus. *Quincy.*

But you of learning and religion,
And virtue, and such ingredients, have made
A *mithridate*, whose operation
Keeps off, or cures, what can be done or said.
Donne.

MITHRIDATE is a composition, in form of an electuary, supposed to serve either as a remedy or a preservative against poisons. See PHARMACY. It takes its name from the inventor, Mithridates VII. king of Pontus. The recipe was found in his cabinet, written with his own hand, and was carried to Rome by Pompey. It was translated into verse by Damocrates, a famous physician; and afterwards by Galen, from whom we have it; though it is supposed to have undergone considerable alterations since the time of its royal prescriber.

MITHRIDATE MUSTARD. See THLASPI.
